pg_similarity.overlap_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.overlap_threshold	Sets the threshold used by the Overlap Coefficient similarity measure.	–
pg_similarity.overlap_tokenizer	Sets the tokenizer for Overlap Coefficientsimilarity measure.	–
pg_similarity.qgram_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.qgram_threshold	Sets the threshold used by the Q-Gram similarity measure.	–
pg_similarity.qgram_tokenizer	Sets the tokenizer for Q-Gram measure.	–
pg_similarity.swg_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.swg_threshold	Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.	–
pg_similarity.sw_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.sw_threshold	Sets the threshold used by the Smith-Waterman similarity measure.	–
pg_stat_statements.max	Sets the maximum number of statements tracked by pg_stat_statements.	–
pg_stat_statements.save	Save pg_stat_statements statistics across server shutdowns.	–

Parameter name	Description	Default
pg_stat_statements.track	Selects which statements are tracked by pg_stat_statements.	–
pg_stat_statements.track_planning	Selects whether planning duration is tracked by pg_stat_statements.	–
pg_stat_statements.track_utility	Selects whether utility commands are tracked by pg_stat_statements.	–
plan_cache_mode	Controls the planner selection of custom or generic plan.	–
port	Sets the TCP port the server listens on.	EndPointPort
postgis.gdal_enabled_drivers	Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.	ENABLE_ALL
quote_all_identifiers	When generating SQL fragments, quote all identifiers.	–
random_page_cost	Sets the planners estimate of the cost of a nonsequentially fetched disk page.	–
rdkit.dice_threshold	Lower threshold of Dice similarity. Molecules with similarity lower than threshold are not similar by # operation.	–
rdkit.do_chiral_sss	Should stereochemistry be taken into account in substructure matching. If false, no stereochemistry information is used in substructure matches.	–
rdkit.tanimoto_threshold	Lower threshold of Tanimoto similarity. Molecules with similarity lower than threshold are not similar by % operation.	–

Parameter name	Description	Default
rds.accepted_password_auth_method	Force authentication for connections with password stored locally.	md5+scram
rds.adaptive_autovacuum	RDS parameter to enable/disable adaptive autovacuum.	1
rds.babelfish_status	RDS parameter to enable/disable Babelfish for Aurora PostgreSQL.	off
rds.enable_plan_management	Enable or disable the apg_plan_mgmt extension.	0

Parameter name	Description	Default
rds.extensions	List of extensions provided by RDS	address_standardizer, address_standardizer_data_us, apg_plan_mgmt, aurora_stat_utils, amcheck, autoinc, aws_commons, aws_ml, aws_s3, aws_lambda, bool_plperl, bloom, btree_gin, btree_gist, citext, cube, dblink, dict_int, dict_xsyn, earthdistance, fuzzystrmatch, hll, hstore, hstore_plperl, insert_username, intagg, intarray, ip4r, isn, jsonb_plperl, lo, log_fdw, ltree, moddatetime, old_snapshot, oracle_fdw, orafce, pgaudit, pgcrypto, pglogical, pgrouting, pgrowlocks, pgstattuple, pgtap, pg_bigm, pg_buffercache, pg_cron, pg_freespacemap, pg_hint_plan, pg_partman, pg_prewarm, pg_proctab,

Parameter name	Description	Default
		pg_repack, pg_similarity, pg_stat_statements, pg_trgm, pg_visibility, plcoffee, plls, plperl, plpgsql, plprofiler, pltcl, plv8, postgis, postgis_tiger_geocoder, postgis_raster, postgis_topology, postgres_fdw, prefix, rdkit, rds_tools, refint, sslinfo, tablefunc, tds_fdw, test_parser, tsm_system_rows, tsm_system_time, unaccent, uuid-ossp
rds.force_admin_logging_level	See log messages for RDS admin user actions in customer databases.	–
rds.force_autovacuum_logging_level	See log messages related to autovacuum operations.	WARNING
rds.force_ssl	Force SSL connections.	0

Parameter name	Description	Default
rds.global_db_rpo	(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated. **Important** This parameter is meant for Aurora PostgreSQL-based global databases. For a nonglobal database, leave it at the default value. For more information about using this parameter, see the section called "Managing RPOs for Aurora PostgreSQL–based global databases".	–
rds.logical_replication	Enables logical decoding.	0
rds.logically_replicate_unlogged_tables	Unlogged tables are logically replicated.	1
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.	4320
rds.pg_stat_ramdisk_size	Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk. This parameter is only available in Aurora PostgreSQL 14 and lower versions.	0
rds.rds_superuser_reserved_connections	Sets the number of connection slots reserved for rds_superusers. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation reserved connections.	2

Parameter name	Description	Default
rds.restrict_password_commands	restricts password-related commands to members of rds_password	–
rds.superuser_variables	List of superuser-only variables for which we elevate rds_superuser modification statements.	session_replication_role
recovery_init_sync_method	Sets the method for synchronizing the data directory before crash recovery.	syncfs
remove_temp_files_after_crash	Remove temporary files after backend crash.	0
restart_after_crash	Reinitialize server after backend crash.	–
row_security	Enable row security.	–
search_path	Sets the schema search order for names that are not schema-qualified.	–
seq_page_cost	Sets the planners estimate of the cost of a sequentially fetched disk page.	–
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.	–
shared_buffers	(8kB) Sets the number of shared memory buffers used by the server.	SUM(DBInstanceClassMemory/12038,-50003)
shared_preload_libraries	Lists shared libraries to preload into server.	pg_stat_statements
ssl	Enables SSL connections.	1
ssl_ca_file	Location of the SSL server authority file.	/rdsdbdata/rds-metadata/ca-cert.pem

Parameter name	Description	Default
ssl_cert_file	Location of the SSL server certificate file.	/rdsdbdata/rds-metadata/server-cert.pem
ssl_ciphers	Sets the list of allowed TLS ciphers to be used on secure connections.	–
ssl_crl_dir	Location of the SSL certificate revocation list directory.	/rdsdbdata/rds-metadata/ssl_crl_dir/
ssl_key_file	Location of the SSL server private key file	/rdsdbdata/rds-metadata/server-key.pem
ssl_max_protocol_version	Sets the maximum SSL/TLS protocol version allowed	–
ssl_min_protocol_version	Sets the minimum SSL/TLS protocol version allowed	TLSv1.2
standard_conforming_strings	Causes ... strings to treat backslashes literally.	–
statement_timeout	(ms) Sets the maximum allowed duration of any statement.	–
stats_temp_directory	Writes temporary statistics files to the specified directory.	/rdsdbdata/db/pg_stat_tmp
superuser_reserved_connections	Sets the number of connection slots reserved for superusers.	3
synchronize_seqscans	Enable synchronized sequential scans.	–
synchronous_commit	Sets the current transactions synchronization level.	on
tcp_keepalives_count	Maximum number of TCP keepalive retransmits.	–

Parameter name	Description	Default
tcp_keepalives_idle	(s) Time between issuing TCP keepalives.	–
tcp_keepalives_interval	(s) Time between TCP keepalive retransmits.	–
temp_buffers	(8kB) Sets the maximum number of temporary buffers used by each session.	–
temp_file_limit	Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables	-1
temp_tablespaces	Sets the tablespace(s) to use for temporary tables and sort files.	–
timezone	Sets the time zone for displaying and interpreting time stamps.	UTC
track_activities	Collects information about executing commands.	–
track_activity_query_size	Sets the size reserved for pg_stat_activity.current_query, in bytes.	4096
track_commit_timestamp	Collects transaction commit time.	–
track_counts	Collects statistics on database activity.	–
track_functions	Collects function-level statistics on database activity.	pl
track_io_timing	Collects timing statistics on database IO activity.	1
track_wal_io_timing	Collects timing statistics for WAL I/O activity.	–

Parameter name	Description	Default
transform_null_equals	Treats expr=NULL as expr IS NULL.	–
update_process_title	Updates the process title to show the active SQL command.	–
vacuum_cost_delay	(ms) Vacuum cost delay in milliseconds.	–
vacuum_cost_limit	Vacuum cost amount available before napping.	–
vacuum_cost_page_dirty	Vacuum cost for a page dirtied by vacuum.	–
vacuum_cost_page_hit	Vacuum cost for a page found in the buffer cache.	–
vacuum_cost_page_miss	Vacuum cost for a page not found in the buffer cache.	0
vacuum_defer_cleanup_age	Number of transactions by which VACUUM and HOT cleanup should be deferred, if any.	–
vacuum_failsafe_age	Age at which VACUUM should trigger failsafe to avoid a wraparound outage.	1200000000
vacuum_freeze_min_age	Minimum age at which VACUUM should freeze a table row.	–
vacuum_freeze_table_age	Age at which VACUUM should scan whole table to freeze tuples.	–
vacuum_multixact_failsafe_age	Multixact age at which VACUUM should trigger failsafe to avoid a wraparound outage.	1200000000
vacuum_multixact_freeze_min_age	Minimum age at which VACUUM should freeze a MultiXactId in a table row.	–

Parameter name	Description	Default
vacuum_multixact_freeze_table_age	Multixact age at which VACUUM should scan whole table to freeze tuples.	–
wal_buffers	(8kB) Sets the number of disk-page buffers in shared memory for WAL.	–
wal_receiver_create_temp_slot	Sets whether a WAL receiver should create a temporary replication slot if no permanent slot is configured.	0
wal_receiver_status_interval	(s) Sets the maximum interval between WAL receiver status reports to the primary.	–
wal_receiver_timeout	(ms) Sets the maximum wait time to receive data from the primary.	30000
wal_sender_timeout	(ms) Sets the maximum time to wait for WAL replication.	–
work_mem	(kB) Sets the maximum memory to be used for query workspaces.	–
xmlbinary	Sets how binary values are to be encoded in XML.	–
xmloption	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.	–

Aurora PostgreSQL instance-level parameters

You can view the instance-level parameters available for a specific Aurora PostgreSQL version using the AWS Management console, the AWS CLI, or the Amazon RDS API. For information about viewing the parameters in an Aurora PostgreSQL DB parameter groups in the RDS console, see Viewing parameter values for a DB parameter group.

Some instance-level parameters aren't available in all versions and some are being deprecated. For information about viewing the parameters of a specific Aurora PostgreSQL version, see Viewing Aurora PostgreSQL DB cluster and DB parameters.

For example, the following table lists the parameters that apply to a specific DB instance in an Aurora PostgreSQL DB cluster. This list was generated by running the describe-db-parameters AWS CLI command with `default.aurora-postgresql14` for the `--db-parameter-group-name` value.

For a listing of the DB cluster parameters for this same default DB parameter group, see Aurora PostgreSQL cluster-level parameters.

Parameter name	Description	Default
apg_enable_batch_mode_function_execution	Enables batch-mode functions to process sets of rows at a time.	–
apg_enable_correlated_any_transform	Enables the planner to transform correlated ANY Sublink (IN/NOT IN subquery to JOIN when possible.	–
apg_enable_function_migration	Enables the planner to migrate eligible scalar functions to the FROM clause.	–
apg_enable_not_in_transform	Enables the planner to transform NOT IN subquery to ANTI JOIN when possible.	–
apg_enable_remove_redundant_inner_joins	Enables the planner to remove redundant inner joins.	–

Parameter name	Description	Default
apg_enable_semijoin_push_down	Enables the use of semijoin filters for hash joins.	–
apg_plan_mgmt.capture_plan_baselines	Capture plan baseline mode. manual - enable plan capture for any SQL statement, off - disable plan capture, automatic - enable plan capture for for statements in pg_stat_statements that satisfy the eligibility criteria.	off
apg_plan_mgmt.max_databases	Sets the maximum number of databases that that may manage queries using apg_plan_mgmt.	10
apg_plan_mgmt.max_plans	Sets the maximum number of plans that may be cached by apg_plan_mgmt.	10000
apg_plan_mgmt.plan_retention_period	Maximum number of days since a plan was last_used before a plan will be automatically deleted.	32
apg_plan_mgmt.unapproved_plan_execution_threshold	Estimated total plan cost below which an Unapproved plan will be executed.	0
apg_plan_mgmt.use_plan_baselines	Use only approved or fixed plans for managed statements.	false
application_name	Sets the application name to be reported in statistics and logs.	–
aurora_compute_plan_id	Monitors query execution plans to detect the execution plans contributing to current database load and to track performance statistics of execution plans over time. For more information, see Monitoring query execution plans for Aurora PostgreSQL.	on

Parameter name	Description	Default
authentication_timeout	(s Sets the maximum allowed time to complete client authentication.	–
auto_explain.log_analyze	Use EXPLAIN ANALYZE for plan logging.	–
auto_explain.log_buffers	Log buffers usage.	–
auto_explain.log_format	EXPLAIN format to be used for plan logging.	–
auto_explain.log_min_duration	Sets the minimum execution time above which plans will be logged.	–
auto_explain.log_nested_statements	Log nested statements.	–
auto_explain.log_timing	Collect timing data, not just row counts.	–
auto_explain.log_triggers	Include trigger statistics in plans.	–
auto_explain.log_verbose	Use EXPLAIN VERBOSE for plan logging.	–
auto_explain.sample_rate	Fraction of queries to process.	–
babelfishpg_tds.listen_addresses	Sets the host name or IP address(es to listen TDS to.	*
babelfishpg_tds.tds_debug_log_level	Sets logging level in TDS, 0 disables logging	1
backend_flush_after	(8Kb Number of pages after which previously performed writes are flushed to disk.	–

Parameter name	Description	Default
bytea_output	Sets the output format for bytea.	–
check_function_bodies	Check function bodies during CREATE FUNCTION.	–
client_connection_check_interval	Sets the time interval between checks for disconnection while running queries.	–
client_min_messages	Sets the message levels that are sent to the client.	–
config_file	Sets the servers main configuration file.	/rdsdbdata/config/postgresql.conf
constraint_exclusion	Enables the planner to use constraints to optimize queries.	–
cpu_index_tuple_cost	Sets the planners estimate of the cost of processing each index entry during an index scan.	–
cpu_operator_cost	Sets the planners estimate of the cost of processing each operator or function call.	–
cpu_tuple_cost	Sets the planners estimate of the cost of processing each tuple (row.	–
cron.database_name	Sets the database to store pg_cron metadata tables	postgres
cron.log_run	Log all jobs runs into the job_run_details table	on
cron.log_statement	Log all cron statements prior to execution.	off
cron.max_running_jobs	Maximum number of jobs that can run concurrently.	5

Parameter name	Description	Default
cron.use_background_workers	Enables background workers for pg_cron	on
cursor_tuple_fraction	Sets the planners estimate of the fraction of a cursors rows that will be retrieved.	–
db_user_namespace	Enables per-database user names.	–
deadlock_timeout	(ms Sets the time to wait on a lock before checking for deadlock.	–
debug_pretty_print	Indents parse and plan tree displays.	–
debug_print_parse	Logs each querys parse tree.	–
debug_print_plan	Logs each querys execution plan.	–
debug_print_rewritten	Logs each querys rewritten parse tree.	–
default_statistics_target	Sets the default statistics target.	–
default_transaction_deferrable	Sets the default deferrable status of new transactions.	–
default_transaction_isolation	Sets the transaction isolation level of each new transaction.	–
default_transaction_read_only	Sets the default read-only status of new transactions.	–
effective_cache_size	(8kB Sets the planners assumption about the size of the disk cache.	SUM(DBInstanceClassMemory/12038,-50003
effective_io_concurrency	Number of simultaneous requests that can be handled efficiently by the disk subsystem.	–

Parameter name	Description	Default
enable_async_append	Enables the planners use of async append plans.	–
enable_bitmapscan	Enables the planners use of bitmap-scan plans.	–
enable_gathermerge	Enables the planners use of gather merge plans.	–
enable_hashagg	Enables the planners use of hashed aggregation plans.	–
enable_hashjoin	Enables the planners use of hash join plans.	–
enable_incremental_sort	Enables the planners use of incremental sort steps.	–
enable_indexonlyscan	Enables the planners use of index-only-scan plans.	–
enable_indexscan	Enables the planners use of index-scan plans.	–
enable_material	Enables the planners use of materialization.	–
enable_memoize	Enables the planners use of memoization	–
enable_mergejoin	Enables the planners use of merge join plans.	–
enable_nestloop	Enables the planners use of nested-loop join plans.	–
enable_parallel_append	Enables the planners use of parallel append plans.	–
enable_parallel_hash	Enables the planners user of parallel hash plans.	–

Parameter name	Description	Default
enable_partition_pruning	Enable plan-time and run-time partition pruning.	–
enable_partitionwise_aggregate	Enables partitionwise aggregation and grouping.	–
enable_partitionwise_join	Enables partitionwise join.	–
enable_seqscan	Enables the planners use of sequential-scan plans.	–
enable_sort	Enables the planners use of explicit sort steps.	–
enable_tidscan	Enables the planners use of TID scan plans.	–
escape_string_warning	Warn about backslash escapes in ordinary string literals.	–
exit_on_error	Terminate session on any error.	–
force_parallel_mode	Forces use of parallel query facilities.	–
from_collapse_limit	Sets the FROM-list size beyond which subqueries are not collapsed.	–
geqo	Enables genetic query optimization.	–
geqo_effort	GEQO: effort is used to set the default for other GEQO parameters.	–
geqo_generations	GEQO: number of iterations of the algorithm.	–
geqo_pool_size	GEQO: number of individuals in the population.	–
geqo_seed	GEQO: seed for random path selection.	–

Parameter name	Description	Default
geqo_selection_bias	GEQO: selective pressure within the populatio n.	–
geqo_threshold	Sets the threshold of FROM items beyond which GEQO is used.	–
gin_fuzzy_search_l imit	Sets the maximum allowed result for exact search by GIN.	–
gin_pending_list_l imit	(kB Sets the maximum size of the pending list for GIN index.	–
hash_mem_multiplier	Multiple of work_mem to use for hash tables.	–
hba_file	Sets the servers hba configuration file.	/rdsdbdata/config/ pg_hba.conf
hot_standby_feedba ck	Allows feedback from a hot standby to the primary that will avoid query conflicts.	on
ident_file	Sets the servers ident configuration file.	/rdsdbdata/config/ pg_ident.conf
idle_in_transactio n_session_timeout	(ms Sets the maximum allowed duration of any idling transaction.	86400000
idle_session_timeout	Terminate any session that has been idle (that is, waiting for a client query, but not within an open transaction, for longer than the specified amount of time	–
join_collapse_limit	Sets the FROM-list size beyond which JOIN constructs are not flattened.	–
lc_messages	Sets the language in which messages are displayed.	–

Parameter name	Description	Default
listen_addresses	Sets the host name or IP address(es to listen to.	*
lo_compat_privileges	Enables backward compatibility mode for privilege checks on large objects.	0
log_connections	Logs each successful connection.	–
log_destination	Sets the destination for server log output.	stderr
log_directory	Sets the destination directory for log files.	/rdsdbdata/log/error
log_disconnections	Logs end of a session, including duration.	–
log_duration	Logs the duration of each completed SQL statement.	–
log_error_verbosity	Sets the verbosity of logged messages.	–
log_executor_stats	Writes executor performance statistics to the server log.	–
log_file_mode	Sets the file permissions for log files.	0644
log_filename	Sets the file name pattern for log files.	postgresql.log.%Y-%m-%d-%H%M
logging_collector	Start a subprocess to capture stderr output and/or csvlogs into log files.	1
log_hostname	Logs the host name in the connection logs.	0
logical_decoding_work_mem	(kB This much memory can be used by each internal reorder buffer before spilling to disk.	–
log_line_prefix	Controls information prefixed to each log line.	%t:%r:%u@%d:%p]:
log_lock_waits	Logs long lock waits.	–

Parameter name	Description	Default
log_min_duration_sample	(ms Sets the minimum execution time above which a sample of statements will be logged. Sampling is determined by log_statement_sample_rate.	–
log_min_duration_statement	(ms Sets the minimum execution time above which statements will be logged.	–
log_min_error_statement	Causes all statements generating error at or above this level to be logged.	–
log_min_messages	Sets the message levels that are logged.	–
log_parameter_max_length	(B When logging statements, limit logged parameter values to first N bytes.	–
log_parameter_max_length_on_error	(B When reporting an error, limit logged parameter values to first N bytes.	–
log_parser_stats	Writes parser performance statistics to the server log.	–
log_planner_stats	Writes planner performance statistics to the server log.	–
log_replication_commands	Logs each replication command.	–
log_rotation_age	(min Automatic log file rotation will occur after N minutes.	60
log_rotation_size	(kB Automatic log file rotation will occur after N kilobytes.	100000
log_statement	Sets the type of statements logged.	–
log_statement_sample_rate	Fraction of statements exceeding log_min_duration_sample to be logged.	–

Parameter name	Description	Default
log_statement_stats	Writes cumulative performance statistics to the server log.	–
log_temp_files	(kB Log the use of temporary files larger than this number of kilobytes.	–
log_timezone	Sets the time zone to use in log messages.	UTC
log_truncate_on_rotation	Truncate existing log files of same name during log rotation.	0
maintenance_io_concurrency	A variant of effective_io_concurrency that is used for maintenance work.	1
maintenance_work_mem	(kB Sets the maximum memory to be used for maintenance operations.	GREATEST(DBInstanceClassMemory/63963136*1024,65536
max_connections	Sets the maximum number of concurrent connections.	LEAST(DBInstanceClassMemory/9531392,5000
max_files_per_process	Sets the maximum number of simultaneously open files for each server process.	–
max_locks_per_transaction	Sets the maximum number of locks per transaction.	64
max_parallel_maintenance_workers	Sets the maximum number of parallel processes per maintenance operation.	–
max_parallel_workers	Sets the maximum number of parallel workers than can be active at one time.	GREATEST($DBInstanceVCPU/2,8
max_parallel_workers_per_gather	Sets the maximum number of parallel processes per executor node.	–

Parameter name	Description	Default
max_pred_locks_per_page	Sets the maximum number of predicate-locked tuples per page.	–
max_pred_locks_per_relation	Sets the maximum number of predicate-locked pages and tuples per relation.	–
max_pred_locks_per_transaction	Sets the maximum number of predicate locks per transaction.	–
max_slot_wal_keep_size	(MB Replication slots will be marked as failed, and segments released for deletion or recycling, if this much space is occupied by WAL on disk.	–
max_stack_depth	(kB Sets the maximum stack depth, in kilobytes.	6144
max_standby_streaming_delay	(ms Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.	14000
max_worker_processes	Sets the maximum number of concurrent worker processes.	GREATEST($DBInstanceVCPU*2,8
min_dynamic_shared_memory	(MB Amount of dynamic shared memory reserved at startup.	–
min_parallel_index_scan_size	(8kB Sets the minimum amount of index data for a parallel scan.	–
min_parallel_table_scan_size	(8kB Sets the minimum amount of table data for a parallel scan.	–
old_snapshot_threshold	(min Time before a snapshot is too old to read pages changed after the snapshot was taken.	–

Parameter name	Description	Default
parallel_leader_participation	Controls whether Gather and Gather Merge also run subplans.	–
parallel_setup_cost	Sets the planners estimate of the cost of starting up worker processes for parallel query.	–
parallel_tuple_cost	Sets the planners estimate of the cost of passing each tuple (row from worker to master backend.	–
pgaudit.log	Specifies which classes of statements will be logged by session audit logging.	–
pgaudit.log_catalog	Specifies that session logging should be enabled in the case where all relations in a statement are in pg_catalog.	–
pgaudit.log_level	Specifies the log level that will be used for log entries.	–
pgaudit.log_parameter	Specifies that audit logging should include the parameters that were passed with the statement.	–
pgaudit.log_relation	Specifies whether session audit logging should create a separate log entry for each relation (TABLE, VIEW, etc. referenced in a SELECT or DML statement.	–
pgaudit.log_statement_once	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.	–
pgaudit.role	Specifies the master role to use for object audit logging.	–

Parameter name	Description	Default
pg_bigm.enable_recheck	It specifies whether to perform Recheck which is an internal process of full text search.	on
pg_bigm.gin_key_limit	It specifies the maximum number of 2-grams of the search keyword to be used for full text search.	0
pg_bigm.last_update	It reports the last updated date of the pg_bigm module.	2013.11.22
pg_bigm.similarity_limit	It specifies the minimum threshold used by the similarity search.	0.3
pg_hint_plan.debug_print	Logs results of hint parsing.	–
pg_hint_plan.enable_hint	Force planner to use plans specified in the hint comment preceding to the query.	–
pg_hint_plan.enable_hint_table	Force planner to not get hint by using table lookups.	–
pg_hint_plan.message_level	Message level of debug messages.	–
pg_hint_plan.parse_messages	Message level of parse errors.	–
pglogical.batch_inserts	Batch inserts if possible	–
pglogical.conflict_log_level	Sets log level used for logging resolved conflicts.	–
pglogical.conflict_resolution	Sets method used for conflict resolution for resolvable conflicts.	–

Parameter name	Description	Default
pglogical.extra_connection_options	connection options to add to all peer node connections	–
pglogical.synchronous_commit	pglogical specific synchronous commit value	–
pglogical.use_spi	Use SPI instead of low-level API for applying changes	–
pg_similarity.block_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.block_threshold	Sets the threshold used by the Block similarity function.	–
pg_similarity.block_tokenizer	Sets the tokenizer for Block similarity function.	–
pg_similarity.cosine_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.cosine_threshold	Sets the threshold used by the Cosine similarity function.	–
pg_similarity.cosine_tokenizer	Sets the tokenizer for Cosine similarity function.	–
pg_similarity.dice_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.dice_threshold	Sets the threshold used by the Dice similarity measure.	–
pg_similarity.dice_tokenizer	Sets the tokenizer for Dice similarity measure.	–
pg_similarity.euclidean_is_normalized	Sets if the result value is normalized or not.	–

Parameter name	Description	Default
pg_similarity.euclidean_threshold	Sets the threshold used by the Euclidean similarity measure.	–
pg_similarity.euclidean_tokenizer	Sets the tokenizer for Euclidean similarity measure.	–
pg_similarity.hamming_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.hamming_threshold	Sets the threshold used by the Block similarity metric.	–
pg_similarity.jaccard_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jaccard_threshold	Sets the threshold used by the Jaccard similarity measure.	–
pg_similarity.jaccard_tokenizer	Sets the tokenizer for Jaccard similarity measure.	–
pg_similarity.jaro_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jaro_threshold	Sets the threshold used by the Jaro similarity measure.	–
pg_similarity.jarowinkler_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jarowinkler_threshold	Sets the threshold used by the Jarowinkler similarity measure.	–
pg_similarity.levenshtein_is_normalized	Sets if the result value is normalized or not.	–

Parameter name	Description	Default
pg_similarity.levenshtein_threshold	Sets the threshold used by the Levenshtein similarity measure.	–
pg_similarity.matching_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.matching_threshold	Sets the threshold used by the Matching Coefficient similarity measure.	–
pg_similarity.matching_tokenizer	Sets the tokenizer for Matching Coefficient similarity measure.	–
pg_similarity.mongeelkan_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.mongeelkan_threshold	Sets the threshold used by the Monge-Elkan similarity measure.	–
pg_similarity.mongeelkan_tokenizer	Sets the tokenizer for Monge-Elkan similarity measure.	–
pg_similarity.nw_gap_penalty	Sets the gap penalty used by the Needleman-Wunsch similarity measure.	–
pg_similarity.nw_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.nw_threshold	Sets the threshold used by the Needleman-Wunsch similarity measure.	–
pg_similarity.overlap_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.overlap_threshold	Sets the threshold used by the Overlap Coefficient similarity measure.	–
pg_similarity.overlap_tokenizer	Sets the tokenizer for Overlap Coefficientsimilarity measure.	–

Parameter name	Description	Default
pg_similarity.qgram_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.qgram_threshold	Sets the threshold used by the Q-Gram similarity measure.	–
pg_similarity.qgram_tokenizer	Sets the tokenizer for Q-Gram measure.	–
pg_similarity.swg_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.swg_threshold	Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.	–
pg_similarity.sw_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.sw_threshold	Sets the threshold used by the Smith-Waterman similarity measure.	–
pg_stat_statements.max	Sets the maximum number of statements tracked by pg_stat_statements.	–
pg_stat_statements.save	Save pg_stat_statements statistics across server shutdowns.	–
pg_stat_statements.track	Selects which statements are tracked by pg_stat_statements.	–
pg_stat_statements.track_planning	Selects whether planning duration is tracked by pg_stat_statements.	–
pg_stat_statements.track_utility	Selects whether utility commands are tracked by pg_stat_statements.	–
postgis.gdal_enabled_drivers	Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.	ENABLE_ALL

Parameter name	Description	Default
quote_all_identifiers	When generating SQL fragments, quote all identifiers.	–
random_page_cost	Sets the planners estimate of the cost of a nonsequentially fetched disk page.	–
rds.enable_memory_management	Improves memory management capabilities in Aurora PostgreSQL 12.17, 13.13, 14.10, 15.5, and higher versions that prevents stability issues and database restarts caused by insufficient free memory. For more information, see Improved memory management in Aurora PostgreSQL.	True
rds.force_admin_logging_level	See log messages for RDS admin user actions in customer databases.	–
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.	4320
rds.memory_allocation_guard	Improves memory management capabilities in Aurora PostgreSQL 11.21, 12.16, 13.12, 14.9, 15.4, and older versions that prevents stability issues and database restarts caused by insufficient free memory. For more information, see Improved memory management in Aurora PostgreSQL.	False
rds.pg_stat_ramdisk_size	Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk.	0
rds.rds_superuser_reserved_connections	Sets the number of connection slots reserved for rds_superusers. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation reserved connections.	2

Parameter name	Description	Default
rds.superuser_variables	List of superuser-only variables for which we elevate rds_superuser modification statements.	session_replication_role
remove_temp_files_after_crash	Remove temporary files after backend crash.	0
restart_after_crash	Reinitialize server after backend crash.	–
row_security	Enable row security.	–
search_path	Sets the schema search order for names that are not schema-qualified.	–
seq_page_cost	Sets the planners estimate of the cost of a sequentially fetched disk page.	–
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.	–
shared_buffers	(8kB Sets the number of shared memory buffers used by the server.	SUM(DBInstanceClassMemory/12038,-50003
shared_preload_libraries	Lists shared libraries to preload into server.	pg_stat_statements
ssl_ca_file	Location of the SSL server authority file.	/rdsdbdata/rds-metadata/ca-cert.pem
ssl_cert_file	Location of the SSL server certificate file.	/rdsdbdata/rds-metadata/server-cert.pem
ssl_crl_dir	Location of the SSL certificate revocation list directory.	/rdsdbdata/rds-metadata/ssl_crl_dir/

Parameter name	Description	Default
ssl_key_file	Location of the SSL server private key file	/rdsdbdata/rds-metadata/server-key.pem
standard_conforming_strings	Causes ... strings to treat backslashes literally.	–
statement_timeout	(ms Sets the maximum allowed duration of any statement.	–
stats_temp_directory	Writes temporary statistics files to the specified directory.	/rdsdbdata/db/pg_stat_tmp
superuser_reserved_connections	Sets the number of connection slots reserved for superusers.	3
synchronize_seqscans	Enable synchronized sequential scans.	–
tcp_keepalives_count	Maximum number of TCP keepalive retransmits.	–
tcp_keepalives_idle	(s Time between issuing TCP keepalives.	–
tcp_keepalives_interval	(s Time between TCP keepalive retransmits.	–
temp_buffers	(8kB Sets the maximum number of temporary buffers used by each session.	–
temp_file_limit	Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables	-1
temp_tablespaces	Sets the tablespace(s to use for temporary tables and sort files.	–
track_activities	Collects information about executing commands.	–

Parameter name	Description	Default
track_activity_query_size	Sets the size reserved for pg_stat_activity.current_query, in bytes.	4096
track_counts	Collects statistics on database activity.	–
track_functions	Collects function-level statistics on database activity.	pl
track_io_timing	Collects timing statistics on database IO activity.	1
transform_–_equals	Treats expr=– as expr IS –.	–
update_process_title	Updates the process title to show the active SQL command.	–
wal_receiver_status_interval	(s Sets the maximum interval between WAL receiver status reports to the primary.	–
work_mem	(kB Sets the maximum memory to be used for query workspaces.	–
xmlbinary	Sets how binary values are to be encoded in XML.	–
xmloption	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.	–

Amazon Aurora PostgreSQL wait events

The following are common wait events for Aurora PostgreSQL. To learn more about wait events and tuning your Aurora PostgreSQL DB cluster, see Tuning with wait events for Aurora PostgreSQL.

Activity:ArchiverMain

The archiver process is waiting for activity.

Activity:AutoVacuumMain

The autovacuum launcher process is waiting for activity.

Activity:BgWriterHibernate

The background writer process is hibernating while waiting for activity.

Activity:BgWriterMain

The background writer process is waiting for activity.

Activity:CheckpointerMain

The checkpointer process is waiting for activity.

Activity:LogicalApplyMain

The logical replication apply process is waiting for activity.

Activity:LogicalLauncherMain

The logical replication launcher process is waiting for activity.

Activity:PgStatMain

The statistics collector process is waiting for activity.

Activity:RecoveryWalAll

A process is waiting for the write-ahead log (WAL) from a stream at recovery.

Activity:RecoveryWalStream

The startup process is waiting for the write-ahead log (WAL) to arrive during streaming recovery.

Activity:SysLoggerMain

The syslogger process is waiting for activity.

Activity:WalReceiverMain

The write-ahead log (WAL) receiver process is waiting for activity.

Activity:WalSenderMain

The write-ahead log (WAL) sender process is waiting for activity.

Activity:WalWriterMain

The write-ahead log (WAL) writer process is waiting for activity.

BufferPin:BufferPin

A process is waiting to acquire an exclusive pin on a buffer.

Client:GSSOpenServer

A process is waiting to read data from the client while establishing a Generic Security Service Application Program Interface (GSSAPI) session.

Client:ClientRead

A backend process is waiting to receive data from a PostgreSQL client. For more information, see Client:ClientRead.

Client:ClientWrite

A backend process is waiting to send more data to a PostgreSQL client. For more information, see Client:ClientWrite.

Client:LibPQWalReceiverConnect

A process is waiting in the write-ahead log (WAL) receiver to establish connection to remote server.

Client:LibPQWalReceiverReceive

A process is waiting in the write-ahead log (WAL) receiver to receive data from remote server.

Client:SSLOpenServer

A process is waiting for Secure Sockets Layer (SSL) while attempting connection.

Client:WalReceiverWaitStart

A process is waiting for startup process to send initial data for streaming replication.

Client:WalSenderWaitForWAL

A process is waiting for the write-ahead log (WAL) to be flushed in the WAL sender process.

Client:WalSenderWriteData

A process is waiting for any activity when processing replies from the write-ahead log (WAL) receiver in the WAL sender process.

CPU

A backend process is active in or is waiting for CPU. For more information, see CPU.

Extension:extension

A backend process is waiting for a condition defined by an extension or module.

IO:AuroraOptimizedReadsCacheRead

A process is waiting for a read from Optimized Reads tiered cache because the page isn't available in shared memory.

IO:AuroraOptimizedReadsCacheSegmentTruncate

A process is waiting for an Optimized Reads tiered cache segment file to be truncated.

IO:AuroraOptimizedReadsCacheWrite

The background writer process is waiting to write in Optimized Reads tiered cache.

IO:AuroraStorageLogAllocate

A session is allocating metadata and preparing for a transaction log write.

IO:BufFileRead

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations read from the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite.

IO:BufFileWrite

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations write to the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite.

IO:ControlFileRead

A process is waiting for a read from the `pg_control` file.

IO:ControlFileSync

A process is waiting for the `pg_control` file to reach durable storage.

IO:ControlFileSyncUpdate

A process is waiting for an update to the `pg_control` file to reach durable storage.

IO:ControlFileWrite

A process is waiting for a write to the `pg_control` file.

IO:ControlFileWriteUpdate

A process is waiting for a write to update the `pg_control` file.

IO:CopyFileRead

A process is waiting for a read during a file copy operation.

IO:CopyFileWrite

A process is waiting for a write during a file copy operation.

IO:DataFileExtend

A process is waiting for a relation data file to be extended.

IO:DataFileFlush

A process is waiting for a relation data file to reach durable storage.

IO:DataFileImmediateSync

A process is waiting for an immediate synchronization of a relation data file to durable storage.

IO:DataFilePrefetch

A process is waiting for an asynchronous prefetch from a relation data file.

IO:DataFileSync

A process is waiting for changes to a relation data file to reach durable storage.

IO:DataFileRead

A backend process tried to find a page in the shared buffers, didn't find it, and so read it from storage. For more information, see IO:DataFileRead.

IO:DataFileTruncate

A process is waiting for a relation data file to be truncated.

IO:DataFileWrite

A process is waiting for a write to a relation data file.

IO:DSMFillZeroWrite

A process is waiting to write zero bytes to a dynamic shared memory backing file.

IO:LockFileAddToDataDirRead

A process is waiting for a read while adding a line to the data directory lock file.

IO:LockFileAddToDataDirSync

A process is waiting for data to reach durable storage while adding a line to the data directory lock file.

IO:LockFileAddToDataDirWrite

A process is waiting for a write while adding a line to the data directory lock file.

IO:LockFileCreateRead

A process is waiting to read while creating the data directory lock file.

IO:LockFileCreateSync

A process is waiting for data to reach durable storage while creating the data directory lock file.

IO:LockFileCreateWrite

A process is waiting for a write while creating the data directory lock file.

IO:LockFileReCheckDataDirRead

A process is waiting for a read during recheck of the data directory lock file.

IO:LogicalRewriteCheckpointSync

A process is waiting for logical rewrite mappings to reach durable storage during a checkpoint.

IO:LogicalRewriteMappingSync

A process is waiting for mapping data to reach durable storage during a logical rewrite.

IO:LogicalRewriteMappingWrite

A process is waiting for a write of mapping data during a logical rewrite.

IO:LogicalRewriteSync

A process is waiting for logical rewrite mappings to reach durable storage.

IO:LogicalRewriteTruncate

A process is waiting for the truncation of mapping data during a logical rewrite.

IO:LogicalRewriteWrite

A process is waiting for a write of logical rewrite mappings.

IO:RelationMapRead

A process is waiting for a read of the relation map file.

IO:RelationMapSync

A process is waiting for the relation map file to reach durable storage.

IO:RelationMapWrite

A process is waiting for a write to the relation map file.

IO:ReorderBufferRead

A process is waiting for a read during reorder buffer management.

IO:ReorderBufferWrite

A process is waiting for a write during reorder buffer management.

IO:ReorderLogicalMappingRead

A process is waiting for a read of a logical mapping during reorder buffer management.

IO:ReplicationSlotRead

A process is waiting for a read from a replication slot control file.

IO:ReplicationSlotRestoreSync

A process is waiting for a replication slot control file to reach durable storage while restoring it to memory.

IO:ReplicationSlotSync

A process is waiting for a replication slot control file to reach durable storage.

IO:ReplicationSlotWrite

A process is waiting for a write to a replication slot control file.

IO:SLRUFlushSync

A process is waiting for simple least-recently used (SLRU) data to reach durable storage during a checkpoint or database shutdown.

IO:SLRURead

A process is waiting for a read of a simple least-recently used (SLRU) page.

IO:SLRUSync

A process is waiting for simple least-recently used (SLRU) data to reach durable storage following a page write.

IO:SLRUWrite

A process is waiting for a write of a simple least-recently used (SLRU) page.

IO:SnapbuildRead

A process is waiting for a read of a serialized historical catalog snapshot.

IO:SnapbuildSync

A process is waiting for a serialized historical catalog snapshot to reach durable storage.

IO:SnapbuildWrite

A process is waiting for a write of a serialized historical catalog snapshot.

IO:TimelineHistoryFileSync

A process is waiting for a timeline history file received through streaming replication to reach durable storage.

IO:TimelineHistoryFileWrite

A process is waiting for a write of a timeline history file received through streaming replication.

IO:TimelineHistoryRead

A process is waiting for a read of a timeline history file.

IO:TimelineHistorySync

A process is waiting for a newly created timeline history file to reach durable storage.

IO:TimelineHistoryWrite

A process is waiting for a write of a newly created timeline history file.

IO:TwophaseFileRead

A process is waiting for a read of a two phase state file.

IO:TwophaseFileSync

A process is waiting for a two phase state file to reach durable storage.

IO:TwophaseFileWrite

A process is waiting for a write of a two phase state file.

IO:WALBootstrapSync

A process is waiting for the write-ahead log (WAL) to reach durable storage during bootstrapping.

IO:WALBootstrapWrite

A process is waiting for a write of a write-ahead log (WAL) page during bootstrapping.

IO:WALCopyRead

A process is waiting for a read when creating a new write-ahead log (WAL) segment by copying an existing one.

IO:WALCopySync

A process is waiting for a new write-ahead log (WAL) segment created by copying an existing one to reach durable storage.

IO:WALCopyWrite

A process is waiting for a write when creating a new write-ahead log (WAL) segment by copying an existing one.

IO:WALInitSync

A process is waiting for a newly initialized write-ahead log (WAL) file to reach durable storage.

IO:WALInitWrite

A process is waiting for a write while initializing a new write-ahead log (WAL) file.

IO:WALRead

A process is waiting for a read from a write-ahead log (WAL) file.

IO:WALSenderTimelineHistoryRead

A process is waiting for a read from a timeline history file during a WAL sender timeline command.

IO:WALSync

A process is waiting for a write-ahead log (WAL) file to reach durable storage.

IO:WALSyncMethodAssign

A process is waiting for data to reach durable storage while assigning a new write-ahead log (WAL) sync method.

IO:WALWrite

A process is waiting for a write to a write-ahead log (WAL) file.

IO:XactSync

A backend process is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. For more information, see IO:XactSync.

IPC:BackupWaitWalArchive

A process is waiting for write-ahead log (WAL) files required for a backup to be successfully archived.

IPC:AuroraOptimizedReadsCacheWriteStop

A process is waiting for the background writer to stop writing into Optimized Reads tiered cache.

IPC:BgWorkerShutdown

A process is waiting for a background worker to shut down.

IPC:BgWorkerStartup

A process is waiting for a background worker to start.

IPC:BtreePage

A process is waiting for the page number needed to continue a parallel B-tree scan to become available.

IPC:CheckpointDone

A process is waiting for a checkpoint to complete.

IPC:CheckpointStart

A process is waiting for a checkpoint to start.

IPC:ClogGroupUpdate

A process is waiting for the group leader to update the transaction status at a transaction's end.

IPC:DamRecordTxAck

A backend process has generated a database activity streams event and is waiting for the event to become durable. For more information, see IPC:DamRecordTxAck.

IPC:ExecuteGather

A process is waiting for activity from a child process while executing a Gather plan node.

IPC:Hash/Batch/Allocating

A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Electing

A process is electing a parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Loading

A process is waiting for other parallel hash participants to finish loading a hash table.

IPC:Hash/Build/Allocating

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/Electing

A process is electing a parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/HashingInner

A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:Hash/Build/HashingOuter

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

IPC:Hash/GrowBatches/Allocating

A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Deciding

A process is electing a parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Electing

A process is electing a parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Finishing

A process is waiting for an elected parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Repartitioning

A process is waiting for other parallel hash participants to finishing repartitioning.

IPC:Hash/GrowBuckets/Allocating

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

IPC:Hash/GrowBuckets/Electing

A process is electing a parallel hash participant to allocate more buckets.

IPC:Hash/GrowBuckets/Reinserting

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

IPC:HashBatchAllocate

A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:HashBatchElect

A process is waiting to elect a parallel hash participant to allocate a hash table.

IPC:HashBatchLoad

A process is waiting for other parallel hash participants to finish loading a hash table.

IPC:HashBuildAllocate

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:HashBuildElect

A process is waiting to elect a parallel hash participant to allocate the initial hash table.

IPC:HashBuildHashInner

A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:'HashBuildHashOuter

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

IPC:HashGrowBatchesAllocate

A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:'HashGrowBatchesDecide

A process is waiting to elect a parallel hash participant to decide on future batch growth.

IPC:HashGrowBatchesElect

A process is waiting to elect a parallel hash participant to allocate more batches.

IPC:HashGrowBatchesFinish

A process is waiting for an elected parallel hash participant to decide on future batch growth.

IPC:HashGrowBatchesRepartition

A process is waiting for other parallel hash participants to finish repartitioning.

IPC:HashGrowBucketsAllocate

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

IPC:HashGrowBucketsElect

A process is waiting to elect a parallel hash participant to allocate more buckets.

IPC:HashGrowBucketsReinsert

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

IPC:LogicalSyncData

A process is waiting for a logical replication remote server to send data for initial table synchronization.

IPC:LogicalSyncStateChange

A process is waiting for a logical replication remote server to change state.

IPC:MessageQueueInternal

A process is waiting for another process to be attached to a shared message queue.

IPC:MessageQueuePutMessage

A process is waiting to write a protocol message to a shared message queue.

IPC:MessageQueueReceive

A process is waiting to receive bytes from a shared message queue.

IPC:MessageQueueSend

A process is waiting to send bytes to a shared message queue.

IPC:ParallelBitmapScan

A process is waiting for a parallel bitmap scan to become initialized.

IPC:ParallelCreateIndexScan

A process is waiting for parallel CREATE INDEX workers to finish a heap scan.

IPC:ParallelFinish

A process is waiting for parallel workers to finish computing.

IPC:ProcArrayGroupUpdate

A process is waiting for the group leader to clear the transaction ID at the end of a parallel operation.

IPC:ProcSignalBarrier

A process is waiting for a barrier event to be processed by all backends.

IPC:Promote

A process is waiting for standby promotion.

IPC:RecoveryConflictSnapshot

A process is waiting for recovery conflict resolution for a vacuum cleanup.

IPC:RecoveryConflictTablespace

A process is waiting for recovery conflict resolution for dropping a tablespace.

IPC:RecoveryPause

A process is waiting for recovery to be resumed.

IPC:ReplicationOriginDrop

A process is waiting for a replication origin to become inactive so it can be dropped.

IPC:ReplicationSlotDrop

A process is waiting for a replication slot to become inactive so it can be dropped.

IPC:SafeSnapshot

A process is waiting to obtain a valid snapshot for a READ ONLY DEFERRABLE transaction.

IPC:SyncRep

A process is waiting for confirmation from a remote server during synchronous replication.

IPC:XactGroupUpdate

A process is waiting for the group leader to update the transaction status at the end of a parallel operation.

Lock:advisory

A backend process requested an advisory lock and is waiting for it. For more information, see Lock:advisory.

Lock:extend

A backend process is waiting for a lock to be released so that it can extend a relation. This lock is needed because only one backend process can extend a relation at a time. For more information, see Lock:extend.

Lock:frozenid

A process is waiting to update `pg_database.datfrozenxid` and `pg_database.datminmxid`.

Lock:object

A process is waiting to get a lock on a nonrelation database object.

Lock:page

A process is waiting to get a lock on a page of a relation.

Lock:Relation

A backend process is waiting to acquire a lock on a relation that is locked by another transaction. For more information, see Lock:Relation.

Lock:spectoken

A process is waiting to get a speculative insertion lock.

Lock:speculative token

A process is waiting to acquire a speculative insertion lock.

Lock:transactionid

A transaction is waiting for a row-level lock. For more information, see Lock:transactionid.

Lock:tuple

A backend process is waiting to acquire a lock on a tuple while another backend process holds a conflicting lock on the same tuple. For more information, see Lock:tuple.

Lock:userlock

A process is waiting to get a user lock.

Lock:virtualxid

A process is waiting to get a virtual transaction ID lock.

LWLock:AddinShmemInit

A process is waiting to manage an extension's space allocation in shared memory.

LWLock:AddinShmemInitLock

A process is waiting to manage space allocation in shared memory.

LWLock:async

A process is waiting for I/O on an async (notify) buffer.

LWLock:AsyncCtlLock

A process is waiting to read or update a shared notification state.

LWLock:AsyncQueueLock

A process is waiting to read or update notification messages.

LWLock:AuroraOptimizedReadsCacheMapping

A process is waiting to associate a data block with a page in the Optimized Reads tiered cache.

LWLock:AutoFile

A process is waiting to update the `postgresql.auto.conf` file.

LWLock:AutoFileLock

A process is waiting to update the `postgresql.auto.conf` file.

LWLock:Autovacuum

A process is waiting to read or update the current state of autovacuum workers.

LWLock:AutovacuumLock

An autovacuum worker or launcher is waiting to update or read the current state of autovacuum workers.

LWLock:AutovacuumSchedule

A process is waiting to ensure that a table selected for autovacuum still needs vacuuming.

LWLock:AutovacuumScheduleLock

A process is waiting to ensure that the table it has selected for a vacuum still needs vacuuming.

LWLock:BackendRandomLock

A process is waiting to generate a random number.

LWLock:BackgroundWorker

A process is waiting to read or update background worker state.

LWLock:BackgroundWorkerLock

A process is waiting to read or update the background worker state.

LWLock:BtreeVacuum

A process is waiting to read or update vacuum-related information for a B-tree index.

LWLock:BtreeVacuumLock

A process is waiting to read or update vacuum-related information for a B-tree index.

LWLock:buffer_content

A backend process is waiting to acquire a lightweight lock on the contents of a shared memory buffer. For more information, see LWLock:buffer_content (BufferContent).

LWLock:buffer_mapping

A backend process is waiting to associate a data block with a buffer in the shared buffer pool. For more information, see LWLock:buffer_mapping.

LWLock:BufferIO

A backend process wants to read a page into shared memory. The process is waiting for other processes to finish their I/O for the page. For more information, see LWLock:BufferIO (IPC:BufferIO).

LWLock:Checkpoint

A process is waiting to begin a checkpoint.

LWLock:CheckpointLock

A process is waiting to perform checkpoint.

LWLock:CheckpointerComm

A process is waiting to manage `fsync` requests.

LWLock:CheckpointerCommLock

A process is waiting to manage `fsync` requests.

LWLock:clog

A process is waiting for I/O on a clog (transaction status) buffer.

LWLock:CLogControlLock

A process is waiting to read or update transaction status.

LWLock:CLogTruncationLock

A process is waiting to run `txid_status` or update the oldest transaction ID available to it.

LWLock:commit_timestamp

A process is waiting for I/O on a commit timestamp buffer.

LWLock:CommitTs

A process is waiting to read or update the last value set for a transaction commit timestamp.

LWLock:CommitTsBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a commit timestamp.

LWLock:CommitTsControlLock

A process is waiting to read or update transaction commit timestamps.

LWLock:CommitTsLock

A process is waiting to read or update the last value set for the transaction timestamp.

LWLock:CommitTsSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a commit timestamp.

LWLock:ControlFile

A process is waiting to read or update the `pg_control` file or create a new write-ahead log (WAL) file.

LWLock:ControlFileLock

A process is waiting to read or update the control file or creation of a new write-ahead log (WAL) file.

LWLock:DynamicSharedMemoryControl

A process is waiting to read or update dynamic shared memory allocation information.

LWLock:DynamicSharedMemoryControlLock

A process is waiting to read or update the dynamic shared memory state.

LWLock:lock_manager

A backend process is waiting to add or examine locks for backend processes. Or it's waiting to join or exit a locking group that is used by parallel query. For more information, see LWLock:lock_manager.

LWLock:LockFastPath

A process is waiting to read or update a process's fast-path lock information.

LWLock:LogicalRepWorker

A process is waiting to read or update the state of logical replication workers.

LWLock:LogicalRepWorkerLock

A process is waiting for an action on a logical replication worker to finish.

LWLock:multixact_member

A process is waiting for I/O on a multixact_member buffer.

LWLock:multixact_offset

A process is waiting for I/O on a multixact offset buffer.

LWLock:MultiXactGen

A process is waiting to read or update shared multixact state.

LWLock:MultiXactGenLock

A process is waiting to read or update a shared multixact state.

LWLock:MultiXactMemberBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member. For more information, see LWLock:MultiXact.

LWLock:MultiXactMemberControlLock

A process is waiting to read or update multixact member mappings.

LWLock:MultiXactMemberSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member. For more information, see LWLock:MultiXact.

LWLock:MultiXactOffsetBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset. For more information, see LWLock:MultiXact.

LWLock:MultiXactOffsetControlLock

A process is waiting to read or update multixact offset mappings.

LWLock:MultiXactOffsetSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset. For more information, see LWLock:MultiXact.

LWLock:MultiXactTruncation

A process is waiting to read or truncate multixact information.

LWLock:MultiXactTruncationLock

A process is waiting to read or truncate multixact information.

LWLock:NotifyBuffer

A process is waiting for I/O on the simple least-recently used (SLRU) buffer for a NOTIFY message.

LWLock:NotifyQueue

A process is waiting to read or update NOTIFY messages.

LWLock:NotifyQueueTail

A process is waiting to update a limit on NOTIFY message storage.

LWLock:NotifyQueueTailLock

A process is waiting to update limit on notification message storage.

LWLock:NotifySLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a NOTIFY message.

LWLock:OidGen

A process is waiting to allocate a new object ID (OID).

LWLock:OidGenLock

A process is waiting to allocate or assign an object ID (OID).

LWLock:oldserxid

A process is waiting for I/O on an oldserxid buffer.

LWLock:OldSerXidLock

A process is waiting to read or record conflicting serializable transactions.

LWLock:OldSnapshotTimeMap

A process is waiting to read or update old snapshot control information.

LWLock:OldSnapshotTimeMapLock

A process is waiting to read or update old snapshot control information.

LWLock:parallel_append

A process is waiting to choose the next subplan during parallel append plan execution.

LWLock:parallel_hash_join

A process is waiting to allocate or exchange a chunk of memory or update counters during a parallel hash plan execution.

LWLock:parallel_query_dsa

A process is waiting for a lock on dynamic shared memory allocation for a parallel query.

LWLock:ParallelAppend

A process is waiting to choose the next subplan during parallel append plan execution.

LWLock:ParallelHashJoin

A process is waiting to synchronize workers during plan execution for a parallel hash join.

Lwlock:ParallelQueryDSA

A process is waiting for dynamic shared memory allocation for a parallel query.

Lwlock:PerSessionDSA

A process is waiting for dynamic shared memory allocation for a parallel query.

Lwlock:PerSessionRecordType

A process is waiting to access a parallel query's information about composite types.

Lwlock:PerSessionRecordTypmod

A process is waiting to access a parallel query's information about type modifiers that identify anonymous record types.

Lwlock:PerXactPredicateList

A process is waiting to access the list of predicate locks held by the current serializable transaction during a parallel query.

Lwlock:predicate_lock_manager

A process is waiting to add or examine predicate lock information.

Lwlock:PredicateLockManager

A process is waiting to access predicate lock information used by serializable transactions.

Lwlock:proc

A process is waiting to read or update the fast-path lock information.

LWLock:ProcArray

A process is waiting to access the shared per-process data structures (typically, to get a snapshot or report a session's transaction ID).

LWLock:ProcArrayLock

A process is waiting to get a snapshot or clearing a transaction Id at a transaction's end.

LWLock:RelationMapping

A process is waiting to read or update a `pg_filenode.map` file (used to track the file-node assignments of certain system catalogs).

LWLock:RelationMappingLock

A process is waiting to update the relation map file used to store catalog-to-file-node mapping.

LWLock:RelCacheInit

A process is waiting to read or update a `pg_internal.init` file (a relation cache initialization file).

LWLock:RelCacheInitLock

A process is waiting to read or write a relation cache initialization file.

LWLock:replication_origin

A process is waiting to read or update the replication progress.

LWLock:replication_slot_io

A process is waiting for I/O on a replication slot.

LWLock:ReplicationOrigin

A process is waiting to create, drop, or use a replication origin.

LWLock:ReplicationOriginLock

A process is waiting to set up, drop, or use a replication origin.

LWLock:ReplicationOriginState

A process is waiting to read or update the progress of one replication origin.

LWLock:ReplicationSlotAllocation

A process is waiting to allocate or free a replication slot.

LWLock:ReplicationSlotAllocationLock

A process is waiting to allocate or free a replication slot.

LWLock:ReplicationSlotControl

A process is waiting to read or update a replication slot state.

LWLock:ReplicationSlotControlLock

A process is waiting to read or update the replication slot state.

LWLock:ReplicationSlotIO

A process is waiting for I/O on a replication slot.

LWLock:SerialBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a serializable transaction conflict.

LWLock:SerializableFinishedList

A process is waiting to access the list of finished serializable transactions.

LWLock:SerializableFinishedListLock

A process is waiting to access the list of finished serializable transactions.

LWLock:SerializablePredicateList

A process is waiting to access the list of predicate locks held by serializable transactions.

LWLock:SerializablePredicateLockListLock

A process is waiting to perform an operation on a list of locks held by serializable transactions.

LWLock:SerializableXactHash

A process is waiting to read or update information about serializable transactions.

LWLock:SerializableXactHashLock

A process is waiting to retrieve or store information about serializable transactions.

LWLock:SerialSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a serializable transaction conflict.

LWLock:SharedTidBitmap

A process is waiting to access a shared tuple identifier (TID) bitmap during a parallel bitmap index scan.

LWLock:SharedTupleStore

A process is waiting to access a shared tuple store during a parallel query.

LWLock:ShmemIndex

A process is waiting to find or allocate space in shared memory.

LWLock:ShmemIndexLock

A process is waiting to find or allocate space in shared memory.

LWLock:SInvalRead

A process is waiting to retrieve messages from the shared catalog invalidation queue.

LWLock:SInvalReadLock

A process is waiting to retrieve or remove messages from a shared invalidation queue.

LWLock:SInvalWrite

A process is waiting to add a message to the shared catalog invalidation queue.

LWLock:SInvalWriteLock

A process is waiting to add a message in a shared invalidation queue.

LWLock:subtrans

A process is waiting for I/O on a subtransaction buffer.

LWLock:SubtransBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a subtransaction.

LWLock:SubtransControlLock

A process is waiting to read or update subtransaction information.

LWLock:SubtransSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a subtransaction.

LWLock:SyncRep

A process is waiting to read or update information about the state of synchronous replication.

LWLock:SyncRepLock

A process is waiting to read or update information about synchronous replicas.

LWLock:SyncScan

A process is waiting to select the starting location of a synchronized table scan.

LWLock:SyncScanLock

A process is waiting to get the start location of a scan on a table for synchronized scans.

LWLock:TablespaceCreate

A process is waiting to create or drop a tablespace.

LWLock:TablespaceCreateLock

A process is waiting to create or drop the tablespace.

LWLock:tbm

A process is waiting for a shared iterator lock on a tree bitmap (TBM).

LWLock:TwoPhaseState

A process is waiting to read or update the state of prepared transactions.

LWLock:TwoPhaseStateLock

A process is waiting to read or update the state of prepared transactions.

LWLock:wal_insert

A process is waiting to insert the write-ahead log (WAL) into a memory buffer.

LWLock:WALBufMapping

A process is waiting to replace a page in write-ahead log (WAL) buffers.

LWLock:WALBufMappingLock

A process is waiting to replace a page in write-ahead log (WAL) buffers.

LWLock:WALInsert

A process is waiting to insert write-ahead log (WAL) data into a memory buffer.

LWLock:WALWrite

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

LWLock:WALWriteLock

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

LWLock:WrapLimitsVacuum

A process is waiting to update limits on transaction ID and multixact consumption.

LWLock:WrapLimitsVacuumLock

A process is waiting to update limits on transaction ID and multixact consumption.

LWLock:XactBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a transaction status.

LWLock:XactSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a transaction status.

LWLock:XactTruncation

A process is waiting to run pg_xact_status or update the oldest transaction ID available to it.

LWLock:XidGen

A process is waiting to allocate a new transaction ID.

LWLock:XidGenLock

A process is waiting to allocate or assign a transaction ID.

Timeout:BaseBackupThrottle

A process is waiting during base backup when throttling activity.

Timeout:PgSleep

A backend process has called the pg_sleep function and is waiting for the sleep timeout to expire. For more information, see Timeout:PgSleep.

Timeout:RecoveryApplyDelay

A process is waiting to apply write-ahead log (WAL) during recovery because of a delay setting.

Timeout:RecoveryRetrieveRetryInterval

A process is waiting during recovery when write-ahead log (WAL) data is not available from any source (pg_wal, archive, or stream).

Timeout:VacuumDelay

A process is waiting in a cost-based vacuum delay point.

For a complete list of PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.

Amazon Aurora PostgreSQL updates

Following, you can find information about Amazon Aurora PostgreSQL engine version releases and updates. You can also find information about how to upgrade your Aurora PostgreSQL engine. For more information about Aurora releases in general, see Amazon Aurora versions.

> **Tip**
>
> You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see *Using Blue/Green Deployments for database updates*.

Topics

- Identifying versions of Amazon Aurora PostgreSQL
- Amazon Aurora PostgreSQL releases and engine versions
- Extension versions for Amazon Aurora PostgreSQL
- Upgrading Amazon Aurora PostgreSQL DB clusters
- Aurora PostgreSQL long-term support (LTS) releases

Identifying versions of Amazon Aurora PostgreSQL

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora database release typically has two version numbers, the database engine version number and the Aurora version number. If an Aurora PostgreSQL release has an Aurora version number, it's included after the engine version number in the Amazon Aurora PostgreSQL releases and engine versions listing.

Aurora version number

Aurora version numbers use the `major.minor.patch` naming scheme. An Aurora patch version includes important bug fixes added to a minor version after its release. To learn more about

Amazon Aurora major, minor, and patch releases, see Amazon Aurora major versions, Amazon Aurora minor versions, and Amazon Aurora patch versions.

You can find out the Aurora version number of your Aurora PostgreSQL DB instance with the following SQL query:

```
postgres=> SELECT aurora_version();
```

Starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers align more closely to the PostgreSQL engine version. For example, querying an Aurora PostgreSQL 13.3 DB cluster returns the following:

```
aurora_version
----------------
 13.3.1
(1 row)
```

Prior releases, such as Aurora PostgreSQL 10.14 DB cluster, return version numbers similar to the following:

```
aurora_version
----------------
 2.7.3
(1 row)
```

PostgreSQL engine version numbers

Starting with PostgreSQL 10, PostgreSQL database engine versions use a *major*.*minor* numbering scheme for all releases. Some examples include PostgreSQL 10.18, PostgreSQL 12.7, and PostgreSQL 13.3.

Releases prior to PostgreSQL 10 used a *major*.*major*.*minor* numbering scheme in which the first two digits make up the major version number and a third digit denotes a minor version. For example, PostgreSQL 9.6 was a major version, with minor versions 9.6.21 or 9.6.22 indicated by the third digit.

Note

The PostgreSQL engine version 9.6 is no longer supported. To upgrade, see Upgrading Amazon Aurora PostgreSQL DB clusters. For version policies and release timelines, see How long Amazon Aurora major versions remain available.

You can find out the PostgreSQL database engine version number with the following SQL query:

```
postgres=> SELECT version();
```

For an Aurora PostgreSQL 13.3 DB cluster, the results are as follows:

```
version
----------------------------------------------------------------------------------------------
 PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC)
 7.4.0, 64-bit
(1 row)
```

Amazon Aurora PostgreSQL releases and engine versions

Amazon Aurora PostgreSQL-Compatible Edition releases are updated regularly. Updates are applied to Aurora PostgreSQL DB clusters during system maintenance windows. When updates are applied depends on the type of update, the AWS Region, and maintenance window setting for the DB cluster. Many of the listed releases include both a PostgreSQL version number and an Amazon Aurora version number. However, starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers aren't used. To identify the version numbers of your Aurora PostgreSQL database, see Identifying versions of Amazon Aurora PostgreSQL.

For information about extensions and modules, see Extension versions for Amazon Aurora PostgreSQL.

Note

For information about Amazon Aurora version policies and release timelines, see How long Amazon Aurora major versions remain available.

For information about support for Amazon Aurora see Amazon RDS FAQs.

To determine which Aurora PostgreSQL DB engine versions are available in an AWS Region, use the describe-db-engine-versions AWS CLI command. For example:

```
aws rds describe-db-engine-versions --engine aurora-postgresql --query '*[].
[EngineVersion]' --output text --region aws-region
```

For a list of AWS Regions, see Aurora PostgreSQL Region availability.

For details about the PostgreSQL versions that are available on Aurora PostgreSQL, see the *Release Notes for Aurora PostgreSQL*.

Extension versions for Amazon Aurora PostgreSQL

You can install and configure various PostgreSQL extensions for use with Aurora PostgreSQL DB clusters. For example, you can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. To learn more about this and other extensions available for Aurora PostgreSQL, see Working with extensions and foreign data wrappers.

For details about the PostgreSQL extensions that are supported on Aurora PostgreSQL, see Extension versions for Amazon Aurora PostgreSQL in *Release Notes for Aurora PostgreSQL*.

Upgrading Amazon Aurora PostgreSQL DB clusters

Amazon Aurora makes new versions of the PostgreSQL database engine available in AWS Regions only after extensive testing. You can upgrade your Aurora PostgreSQL DB clusters to the new version when it's available in your Region.

Depending on the version of Aurora PostgreSQL that your DB cluster is currently running, an upgrade to the new release is either a minor upgrade or a major upgrade. For example, upgrading an Aurora PostgreSQL 11.15 DB cluster to Aurora PostgreSQL 13.6 is a *major version upgrade*. Upgrading an Aurora PostgreSQL 13.3 DB cluster to Aurora PostgreSQL 13.7 is a *minor version upgrade*. In the following topics, you can find information about how to perform both types of upgrades.

Contents

Overview of the Aurora PostgreSQL upgrade processes

The differences between major and minor version upgrades are as follows:

Minor version upgrades and patches

Minor version upgrades and patches include only those changes that are backward-compatible with existing applications. Minor version upgrades and patches become available to you only after Aurora PostgreSQL tests and approves them.

Minor version upgrades can be applied for you automatically by Aurora. When you create a new Aurora PostgreSQL DB cluster, the **Enable minor version upgrade** option is preselected. Unless you turn off this option, minor version upgrades are applied automatically during your scheduled maintenance window. For more information about the automatic minor version upgrade (AmVU) option and how to modify your Aurora DB cluster to use it, see Automatic minor version upgrades for Aurora DB clusters.

If the automatic minor version upgrade option isn't set for your Aurora PostgreSQL DB cluster, your Aurora PostgreSQL isn't automatically upgraded to the new minor version. Instead, when a new minor version is released in your AWS Region and your Aurora PostgreSQL DB cluster is running an older minor version, Aurora prompts you to upgrade. It does so by adding a recommendation to the maintenance tasks for your cluster.

Patches aren't considered an upgrade, and they aren't applied automatically. Aurora PostgreSQL prompts you to apply any patches by adding a recommendation to maintenance tasks for your Aurora PostgreSQL DB cluster. For more information, see How to perform minor version upgrades and apply patches.

Note

Patches that resolve security or other critical issues are also added as maintenance tasks. However, these patches are required. Make sure to apply security patches to your Aurora PostgreSQL DB cluster when they become available in your pending maintenance tasks.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. However, after Aurora PostgreSQL versions 14.3.3, 13.7.3, 12.11.3, 11.16.3, 10.21.3 and other higher releases of these minor versions and newer major versions, the upgrade process uses the zero-downtime patching (ZDP) feature. This feature minimizes outages, and in most cases completely eliminates them. For more information, see Minor release upgrades and zero-downtime patching.

Note

ZDP isn't supported in the following cases:

- When Aurora PostgreSQL DB clusters are configured as Aurora Serverless v1.
- When Aurora PostgreSQL DB clusters are configured as Aurora global database in the secondary AWS Regions.
- During the upgrade of reader instances in Aurora global database.
- During OS patches and OS upgrades.

ZDP is supported for Aurora PostgreSQL DB clusters that are configured as Aurora Serverless v2.

Major version upgrades

Unlike for minor version upgrades and patches, Aurora PostgreSQL doesn't have an automatic major version upgrade option. New major PostgreSQL versions might contain database changes that aren't backward-compatible with existing applications. The new functionality can cause your existing applications to stop working correctly.

To prevent any issues, we strongly recommend that you follow the process outlined in Testing an upgrade of your production DB cluster to a new major version before upgrading the DB instances in your Aurora PostgreSQL DB clusters. First ensure that your applications can run on the new version by following that procedure. Then you can manually upgrade your Aurora PostgreSQL DB cluster to the new version.

The upgrade process involves the possibility of brief outage when all the instances in the cluster are upgraded to the new version. The preliminary planning process also takes time. We recommend that you always perform upgrade tasks during your cluster's maintenance window or when operations are minimal. For more information, see How to perform a major version upgrade.

> **Note**
>
> Both minor version upgrades and major version upgrades might involve brief outages. For that reason, we recommend strongly that you perform or schedule upgrades during your maintenance window or during other periods of low utilization.

Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in Collations supported in Aurora PostgreSQL.

Getting a list of available versions in your AWS Region

You can get a list of all engine versions available as upgrade targets for your Aurora PostgreSQL DB cluster by querying your AWS Region using the describe-db-engine-versions AWS CLI command, as follows.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version version-number \
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output text
```

For example, to identify the valid upgrade targets for an Aurora PostgreSQL version 12.10 DB cluster, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version 12.10 \
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version 12.10 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output text
```

In this table, you can find both major and minor version upgrade targets that are available for various Aurora PostgreSQL DB versions.

Curre sourc versi	**Upgrade targets**			
16.1	16			
15.6	16			
15.5	16	16	15	
15.4	16	16	15	15

Current source version	Upgrade targets																						
15.3	16	16	15	15	15																		
15.2	16	16	15	15	15	15																	
14.11	16	15																					
14.10	16	16	15	15																			
14.9	16	16	15	15	15	14	14																
14.8	16	16	15	15	15	15	15	14	14	14													
14.7	16	16	15	15	15	15	15	14	14	14	14												
14.6	16	16	15	15	15	15	15	14	14	14	14	14											
14.5	16	16	15	15	15	15	15	14	14	14	14	14	14										
14.4	16	16	15	15	15	15	15	14	14	14	14	14	14	14									
14.3	16	16	15	15	15	15	15	14	14	14	14	14	14	14	14								
13.14	16	15	14																				
13.13	16	16	15	15	14	14																	
13.12	16	16	15	15	15	14	14	14															
13.11	16	16	15	15	15	15	14	14	14	14													
13.10	16	16	15	15	15	15	15	14	14	14	14	14	13	13	13	13							
13.9	16	16	15	15	15	15	15	14	14	14	14	14	14	13	13	13							
13.8	16	16	15	15	15	15	15	14	14	14	14	14	14	14	13	13	13	13	13	13			
13.7	16	16	15	15	15	15	15	14	14	14	14	14	14	14	14	14	13	13	13	13	13	13	13

Curre sourc versi	Upgrade targets																										
12.18	16	15	14	13																							
12.17	16	16	15	15	14	14	13																				
12.16	16	16	15	15	15	14	14	14	13	13	13																
12.15	16	16	15	15	15	15	14	14	14	14	13	13	13	13													
12.14	16	16	15	15	15	15	15	15	14	14	14	14	14	13	13	13	13	13	12								
12.13	16	16	15	15	15	15	15	14	14	14	14	14	14	13	13	13	13	13	13	12	12	12	12				
12.12	16	16	15	15	15	15	15	14	14	14	14	14	14	14	13	13	13	13	13	13	12	12	12	13	12	12	12	[illegible]
12.11	16	16	15	15	15	15	15	14	14	14	14	14	14	14	14	13	13	13	13	13	13	13	13	12	12	12	12	[illegible]
12.9	16	16	15	15	15	15	15	14	14	14	14	14	13	13	13	13	13	13	13	13	12	12	12	12	12	12	12	[illegible]
11.21	16	16	15	15	15	14	14	14	13	13	13	12	12															
11.9	16	16	15	15	15	15	15	14	14	14	14	14	14	13	13	13	13	13	13	12	12	12	12	12	12	12	12	11.21

For any version that you're considering, always check the availability of your cluster's DB instance class. For example, `db.r4` isn't supported for Aurora PostgreSQL 13. If your Aurora PostgreSQL DB cluster currently uses a db.r4 instance class, you need to move to db.r5 before trying to upgrade. For more information about DB instance classes, including which ones are Graviton2-based and which ones are Intel-based, see Aurora DB instance classes.

How to perform a major version upgrade

Major version upgrades might contain database changes that are not backward-compatible with previous versions of the database. New functionality in a new version can cause your existing applications to stop working correctly. To avoid issues, Amazon Aurora doesn't apply major version upgrades automatically. Rather, we recommend that you carefully plan for a major version upgrade by following these steps:

1. Choose the major version that you want from the list of available targets from those listed for your version in the table. You can get a precise list of versions available in your AWS Region for your current version by using the AWS CLI. For details, see Getting a list of available versions in your AWS Region.
2. Verify that your applications work as expected on a trial deployment of the new version. For information about the complete process, see Testing an upgrade of your production DB cluster to a new major version.
3. After verifying that your applications work as expected on the trial deployment, you can upgrade your cluster. For details, see Upgrading the Aurora PostgreSQL engine to a new major version.

> **Note**
>
> You can perform a major version upgrade from Babelfish for Aurora PostgreSQL 13-based versions starting from 13.6 to Aurora PostgreSQL 14-based versions starting from 14.6. Babelfish for Aurora PostgreSQL 13.4 and 13.5 don't support major version upgrade.

You can get a list of engine versions available as major version upgrade targets for your Aurora PostgreSQL DB cluster by querying your AWS Region using the describe-db-engine-versions AWS CLI command, as follows.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version version-number \
  --query 'DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version version-number ^
  --query "DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
{EngineVersion:EngineVersion}" ^
```

```
  --output text
```

In some cases, the version that you want to upgrade to isn't a target for your current version. In such cases, use the information in the versions table to perform minor version upgrades until your cluster is at a version that has your chosen target in its row of targets.

Testing an upgrade of your production DB cluster to a new major version

Each new major version includes enhancements to the query optimizer that are designed to improve performance. However, your workload might include queries that result in a worse performing plan in the new version. That's why we recommend that you test and review performance before upgrading in production. You can manage query plan stability across versions by using the Query Plan Management (QPM) extension, as detailed in Ensuring plan stability after a major version upgrade.

Before upgrading your production Aurora PostgreSQL DB clusters to a new major version, we strongly recommend that you test the upgrade to verify that all your applications work correctly:

1. Have a version-compatible parameter group ready.

   If you are using a custom DB instance or DB cluster parameter group, you can choose from two options:

   a. Specify the default DB instance, DB cluster parameter group, or both for the new DB engine version.

   b. Create your own custom parameter group for the new DB engine version.

   If you associate a new DB instance or DB cluster parameter group as a part of the upgrade request, make sure to reboot the database after the upgrade completes to apply the parameters. If a DB instance needs to be rebooted to apply the parameter group changes, the instance's parameter group status shows `pending-reboot`. You can view an instance's parameter group status in the console or by using a CLI command such as describe-db-instances or describe-db-clusters.

2. Check for unsupported usage:

   - Commit or roll back all open prepared transactions before attempting an upgrade. You can use the following query to verify that there are no open prepared transactions on your instance.

     ```
     SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
     ```

- Remove all uses of the *reg** data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the *reg** data types. The pg_upgrade utility (used by Amazon Aurora to do the upgrade) can't persist this data type. To learn more about this utility, see [pg_upgrade]() in the PostgreSQL documentation.

  To verify that there are no uses of unsupported *reg** data types, use the following query for each database.

  ```
  SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
   pg_catalog.pg_attribute a
    WHERE c.oid = a.attrelid
        AND NOT a.attisdropped
        AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                           'pg_catalog.regprocedure'::pg_catalog.regtype,
                           'pg_catalog.regoper'::pg_catalog.regtype,
                           'pg_catalog.regoperator'::pg_catalog.regtype,
                           'pg_catalog.regconfig'::pg_catalog.regtype,
                           'pg_catalog.regdictionary'::pg_catalog.regtype)
        AND c.relnamespace = n.oid
        AND n.nspname NOT IN ('pg_catalog', 'information_schema');
  ```

- If you are upgrading an Aurora PostgreSQL version 10.18 or higher DB cluster that has the `pgRouting` extension installed, drop the extension before upgrading to version 12.4 or higher.

  If you are upgrading an Aurora PostgreSQL 10.x version that has the extension `pg_repack` version 1.4.3 installed, drop the extension before upgrading to any higher version.

3. Check for template1 and template0 databases.

   For a successful upgrade, template 1 and template 0 databases must exist and should be listed as a template. To check on this, use the following command:

   ```
   SELECT datname, datistemplate FROM pg_database;

   datname    | datistemplate
   -----------+---------------
   template0  | t
   rdsadmin   | f
   template1  | t
   postgres   | f
   ```

In the command output, the `datistemplate` value for template1 and template0 databases should be `t`.

4. Drop logical replication slots.

   The upgrade process can't proceed if the Aurora PostgreSQL DB cluster is using any logical replication slots. Logical replication slots are typically used for short-term data migration tasks, such as migrating data using AWS DMS or for replicating tables from the database to data lakes, BI tools, or other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that exist, and confirm that it's okay to delete them. You can check for logical replication slots using the following query:

   ```
   SELECT * FROM pg_replication_slots;
   ```

   If logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade. However, if the logical replication slots aren't needed, you can delete them using the following SQL:

   ```
   SELECT pg_drop_replication_slot(slot_name);
   ```

   Logical replication scenarios that use the `pglogical` extension also need to have slots dropped from the publisher node for a successful major version upgrade on that node. However, you can restart the replication process from the subscriber node after the upgrade. For more information, see Reestablishing logical replication after a major upgrade.

5. Perform a backup.

   The upgrade process creates a DB cluster snapshot of your DB cluster during upgrading. If you also want to do a manual backup before the upgrade process, see Creating a DB cluster snapshot for more information.

6. Upgrade certain extensions to the latest available version before performing the major version upgrade. The extensions to update include the following:

   - `pgRouting`
   - `postgis_raster`
   - `postgis_tiger_geocoder`
   - `postgis_topology`
   - `address_standardizer`

- address_standardizer_data_us

Run the following command for each extension that's currently installed.

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see Upgrading PostgreSQL extensions. To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension.

7. If you're upgrading to version 11.x, drop the extensions that it doesn't support before performing the major version upgrade. The extensions to drop include:

   - chkpass
   - tsearch2

8. Drop unknown data types, depending on your target version.

   PostgreSQL version 10 doesn't support the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to version 10 shows an error message such as the following.

   ```
   Database instance is in a state that cannot be upgraded: PreUpgrade checks failed: 
   The instance could not be upgraded because the 'unknown' data type is used in user
    tables. 
   Please remove all usages of the 'unknown' data type and try again."
   ```

   To find the unknown data type in your database so that you can remove such columns or change them to supported data types, use the following SQL code for each database.

   ```
   SELECT n.nspname, c.relname, a.attname
       FROM pg_catalog.pg_class c,
       pg_catalog.pg_namespace n,
       pg_catalog.pg_attribute a
       WHERE c.oid = a.attrelid AND NOT a.attisdropped AND
       a.atttypid = 'pg_catalog.unknown'::pg_catalog.regtype AND
       c.relkind IN ('r','m','c') AND
       c.relnamespace = n.oid AND
       n.nspname !~ '^pg_temp_' AND
       n.nspname !~ '^pg_toast_temp_' AND n.nspname NOT IN ('pg_catalog',
    'information_schema');
   ```

9. Perform a dry-run upgrade.

We highly recommend testing a major version upgrade on a duplicate of your production database before trying the upgrade on your production database. You can monitor the execution plans on the duplicate test instance for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or clone your database. For more information, see Restoring from a snapshot or Cloning a volume for an Amazon Aurora DB cluster.

For more information, see Upgrading the Aurora PostgreSQL engine to a new major version.

10. Upgrade your production instance.

    When your dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Upgrading the Aurora PostgreSQL engine to a new major version.

    > **Note**
    >
    > During the upgrade process, Aurora PostgreSQL takes a DB cluster snapshot if the cluster's backup retention period is greater than 0. You can't do a point-in-time restore of your cluster during this process. Later, you can perform a point-in-time restore to times before the upgrade began and after the automatic snapshot of your instance has completed. However, you can't perform a point-in-time restore to a previous minor version.

    For information about an upgrade in progress, you can use Amazon RDS to view two logs that the pg_upgrade utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon Aurora appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon Aurora log files.

11. Upgrade PostgreSQL extensions. The PostgreSQL upgrade process doesn't upgrade any PostgreSQL extensions. For more information, see Upgrading PostgreSQL extensions.

Post-upgrade recommendations

After you complete a major version upgrade, we recommend the following:

- Run the ANALYZE operation to refresh the pg_statistic table. You should do this for every database on all your PostgreSQL DB instances. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

  ```
  ANALYZE VERBOSE;
  ```

  The VERBOSE flag is optional, but using it shows you the progress. For more information, see ANALYZE in the PostgreSQL documentation.

  > **Note**
  >
  > Run ANALYZE on your system after the upgrade to avoid performance issues.

- If you upgraded to PostgreSQL version 10, run REINDEX on any hash indexes you have. Hash indexes were changed in version 10 and must be rebuilt. To locate invalid hash indexes, run the following SQL for each database that contains hash indexes.

  ```
  SELECT idx.indrelid::regclass AS table_name,
     idx.indexrelid::regclass AS index_name
  FROM pg_catalog.pg_index idx
     JOIN pg_catalog.pg_class cls ON cls.oid = idx.indexrelid
     JOIN pg_catalog.pg_am am ON am.oid = cls.relam
  WHERE am.amname = 'hash'
  AND NOT idx.indisvalid;
  ```

- We recommend that you test your application on the upgraded database with a similar workload to verify that everything works as expected. After the upgrade is verified, you can delete this test instance.

Upgrading the Aurora PostgreSQL engine to a new major version

When you initiate the upgrade process to a new major version, Aurora PostgreSQL takes a snapshot of the Aurora DB cluster before it makes any changes to your cluster. This snapshot is created for major version upgrades only, not minor version upgrades. When the upgrade process completes, you can find this snapshot among the manual snapshots listed under **Snapshots** in the RDS console. The snapshot name includes preupgrade as its prefix, the name of your Aurora

PostgreSQL DB cluster, the source version, the target version, and the date and timestamp, as shown in the following example.

```
preupgrade-docs-lab-apg-global-db-12-8-to-13-6-2022-05-19-00-19
```

After the upgrade completes, you can use the snapshot that Aurora created and stored in your manual snapshot list to restore the DB cluster to its previous version, if necessary.

Tip

In general, snapshots provide many ways to restore your Aurora DB cluster to various points in time. To learn more, see Restoring from a DB cluster snapshot and Restoring a DB cluster to a specified time. However, Aurora PostgreSQL doesn't support using a snapshot to restore to a previous minor version.

During the major version upgrade process, Aurora allocates a volume and clones the source Aurora PostgreSQL DB cluster. If the upgrade fails for any reason, Aurora PostgreSQL uses the clone to roll back the upgrade. After more than 15 clones of a source volume are allocated, subsequent clones become full copies and take longer. This can cause the upgrade process also to take longer. If Aurora PostgreSQL rolls back the upgrade, be aware of the following:

- You might see billing entries and metrics for both the original volume and the cloned volume allocated during the upgrade. Aurora PostgreSQL cleans up the extra volume after the cluster backup retention window is beyond the time of the upgrade.
- The next cross-Region snapshot copy from this cluster will be a full copy instead of an incremental copy.

To safely upgrade the DB instances that make up your cluster, Aurora PostgreSQL uses the pg_upgrade utility. After the writer upgrade completes, each reader instance experiences a brief outage while it's upgraded to the new major version. To learn more about this PostgreSQL utility, see pg_upgrade in the PostgreSQL documentation.

You can upgrade your Aurora PostgreSQL DB cluster to a new version by using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To upgrade the engine version of a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon Aurora DB cluster.
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of a DB cluster, use the modify-db-cluster AWS CLI command. Specify the following parameters:

- `--db-cluster-identifier` – The name of the DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.
- `--allow-major-version-upgrade` – A required flag when the `--engine-version` parameter is a different major version than the DB cluster's current major version.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --engine-version new_version \
    --allow-major-version-upgrade \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --engine-version new_version ^
    --allow-major-version-upgrade ^
    --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB cluster, use the ModifyDBCluster operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example *mydbcluster*.
- `EngineVersion` – The version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `AllowMajorVersionUpgrade` – A required flag when the `EngineVersion` parameter is a different major version than the DB cluster's current major version.
- `ApplyImmediately` – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Major upgrades for global databases

For an Aurora global database cluster, the upgrade process upgrades all DB clusters that make up your Aurora global database at the same time. It does so to ensure that each runs the same Aurora PostgreSQL version. It also ensures that any changes to system tables, data file formats, and so on, are automatically replicated to all secondary clusters.

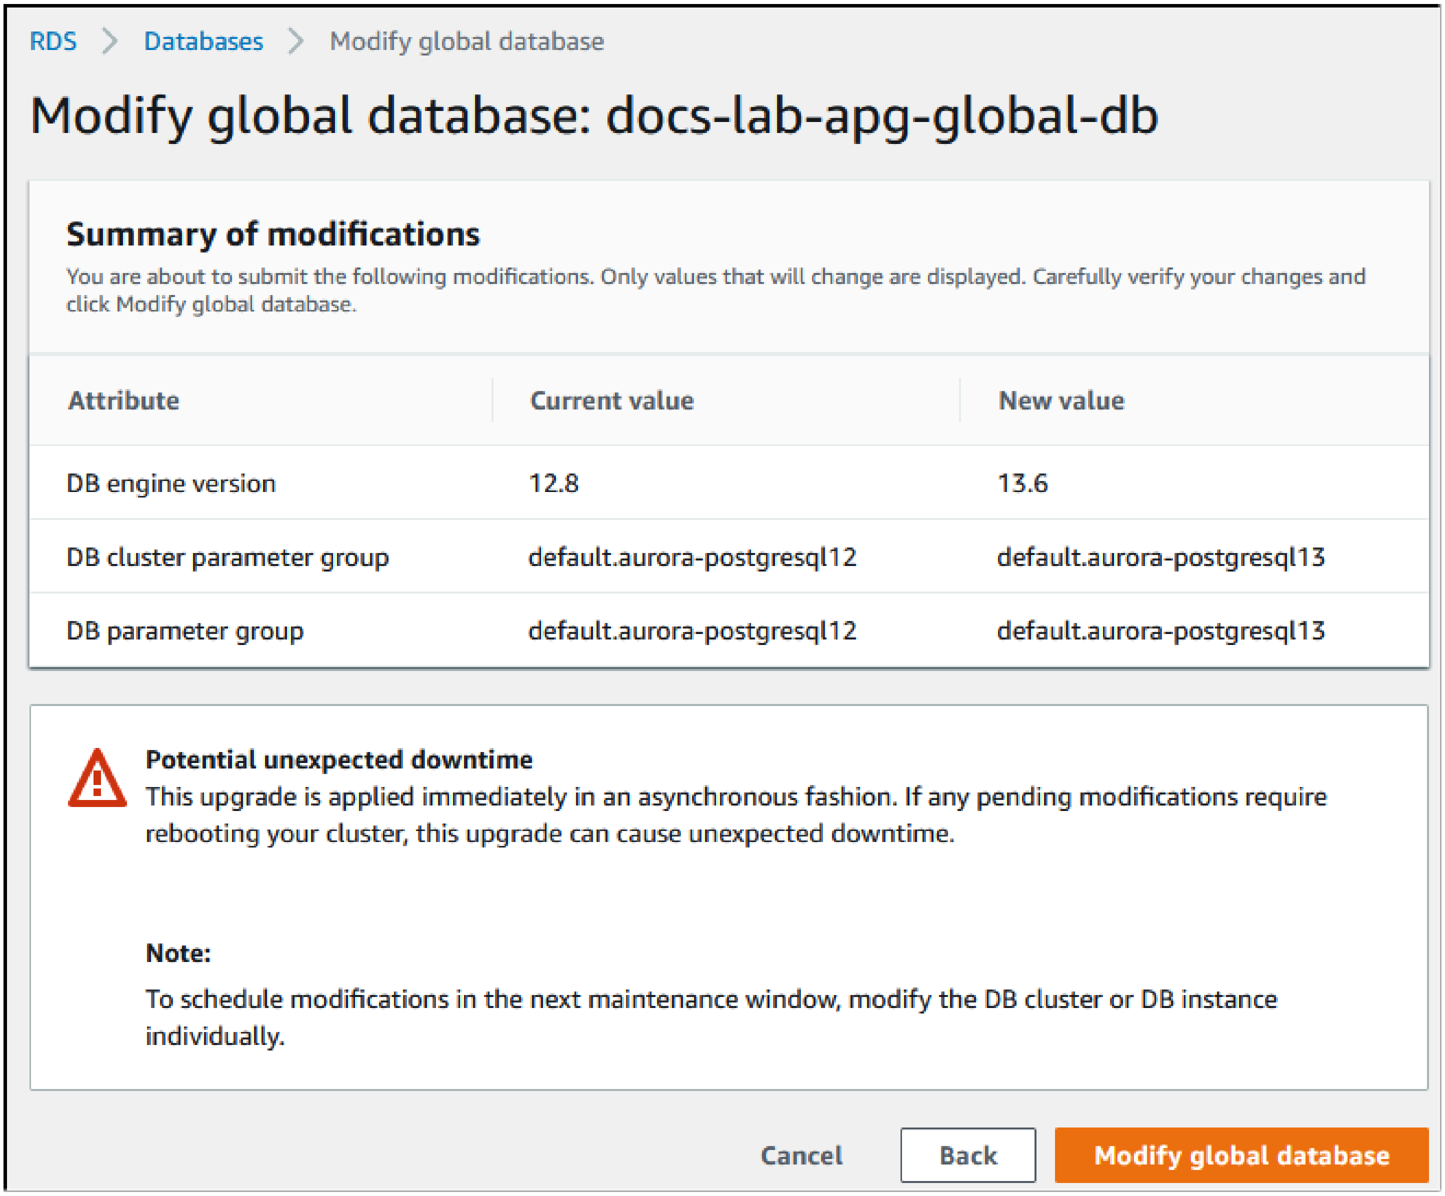
To upgrade a global database cluster to a new major version of Aurora PostgreSQL, we recommend that you test your applications on the upgraded version, as detailed in Testing an upgrade of your production DB cluster to a new major version. Be sure to prepare your DB cluster parameter group and DB parameter group settings for each AWS Region in your Aurora global database before the upgrade as detailed in step 1. of Testing an upgrade of your production DB cluster to a new major version.

If your Aurora PostgreSQL global database cluster has a recovery point objective (RPO) set for its `rds.global_db_rpo` parameter, make sure to reset the parameter before upgrading. The major version upgrade process doesn't work if the RPO is turned on. By default, this parameter is turned off. For more information about Aurora PostgreSQL global databases and RPO, see Managing RPOs for Aurora PostgreSQL–based global databases.

If you verify that your applications can run as expected on the trial deployment of the new version, you can start the upgrade process. To do so, see Upgrading the Aurora PostgreSQL engine to a new major version. Be sure to choose the top-level item from the **Databases** list in the RDS console, **Global database**, as shown in the following image.

	DB identifier	Role	Engine	Region & AZ	Size
○	⊞ docs-lab-apg-aiml	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
●	⊟ docs-lab-apg-global-db	Global database	Aurora PostgreSQL	2 regions	2 clusters
○	⊟ docs-lab-apg-global-12-7	Primary cluster	Aurora PostgreSQL	us-west-1	2 instances
○	docs-lab-apg-global-12-7-instance-1	Writer instance	Aurora PostgreSQL	us-west-1c	db.r6g.large
○	docs-lab-apg-global-12-7-instance-1-us-west-1a	Reader instance	Aurora PostgreSQL	us-west-1a	db.r6g.large
○	⊟ docs-lab-apg-global-db-cluster-northwest	Secondary cluster	Aurora PostgreSQL	us-west-2	2 instances
○	docs-lab-apg-global-db-instance-north	Reader instance	Aurora PostgreSQL	us-west-2c	db.r6g.large
○	docs-lab-apg-global-db-instance-north-us-west-2b	Reader instance	Aurora PostgreSQL	us-west-2b	db.r6g.large
○	⊞ docs-lab-apg-main	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
○	docs-lab-apg-sless-test-aws-s3	Serverless	Aurora PostgreSQL	us-west-1	0 capacity units

As with any modification, you can confirm that you want the process to proceed when prompted.



Modify global database: docs-lab-apg-global-db

Summary of modifications

You are about to submit the following modifications. Only values that will change are displayed. Carefully verify your changes and click Modify global database.

Attribute	Current value	New value
DB engine version	12.8	13.6
DB cluster parameter group	default.aurora-postgresql12	default.aurora-postgresql13
DB parameter group	default.aurora-postgresql12	default.aurora-postgresql13

Potential unexpected downtime
This upgrade is applied immediately in an asynchronous fashion. If any pending modifications require rebooting your cluster, this upgrade can cause unexpected downtime.

Note:

To schedule modifications in the next maintenance window, modify the DB cluster or DB instance individually.

Rather than using the console, you can start the upgrade process by using the AWS CLI or the RDS API. As with the console, you operate on the Aurora global database cluster rather than any of its constituents, as follows:

- Use the modify-global-cluster AWS CLI command to start the upgrade for your Aurora global database by using the AWS CLI.
- Use the ModifyGlobalCluster API to start the upgrade.

Before performing a minor version upgrade

We recommend that you perform the following actions to reduce the downtime during a minor version upgrade:

- The Aurora DB cluster maintenance should be performed during a period of low traffic. Use Performance Insights to identify these time periods in order to configure the maintenance windows correctly. For more information on Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS. For more information on DB cluster maintenance window, Adjusting the preferred DB cluster maintenance window.
- Use AWS SDKs that support exponential backoff and jitter as a best practice. For more information, see Exponential Backoff And Jitter.

How to perform minor version upgrades and apply patches

Minor version upgrades and patches become available in AWS Regions only after rigorous testing. Before releasing upgrades and patches, Aurora PostgreSQL tests to ensure that known security issues, bugs, and other issues that emerge after the release of the minor community version don't disrupt overall Aurora PostgreSQL fleet stability.

As Aurora PostgreSQL makes new minor versions available, the instances that make up your Aurora PostgreSQL DB cluster can be automatically upgraded during your specified maintenance window. For this to happen, your Aurora PostgreSQL DB cluster must have the **Enable auto minor version upgrade** option turned on. All DB instances that make up your Aurora PostgreSQL DB cluster must have the automatic minor version upgrade (AmVU) option turned on so that the minor upgrade to be applied throughout the cluster.

> **Tip**
>
> Make sure that the **Enable auto minor version upgrade** option is turned on for all PostgreSQL DB instances that make up your Aurora PostgreSQL DB cluster. This option must be turned on for every instance in the DB cluster to work. For information on how to set **Auto minor version upgrade**, and how the setting works when applied at the cluster and instance levels, see Automatic minor version upgrades for Aurora DB clusters.

You can check the value of the **Enable auto minor version upgrade** option for all your Aurora PostgreSQL DB clusters by using the describe-db-instances AWS CLI command with the following query.

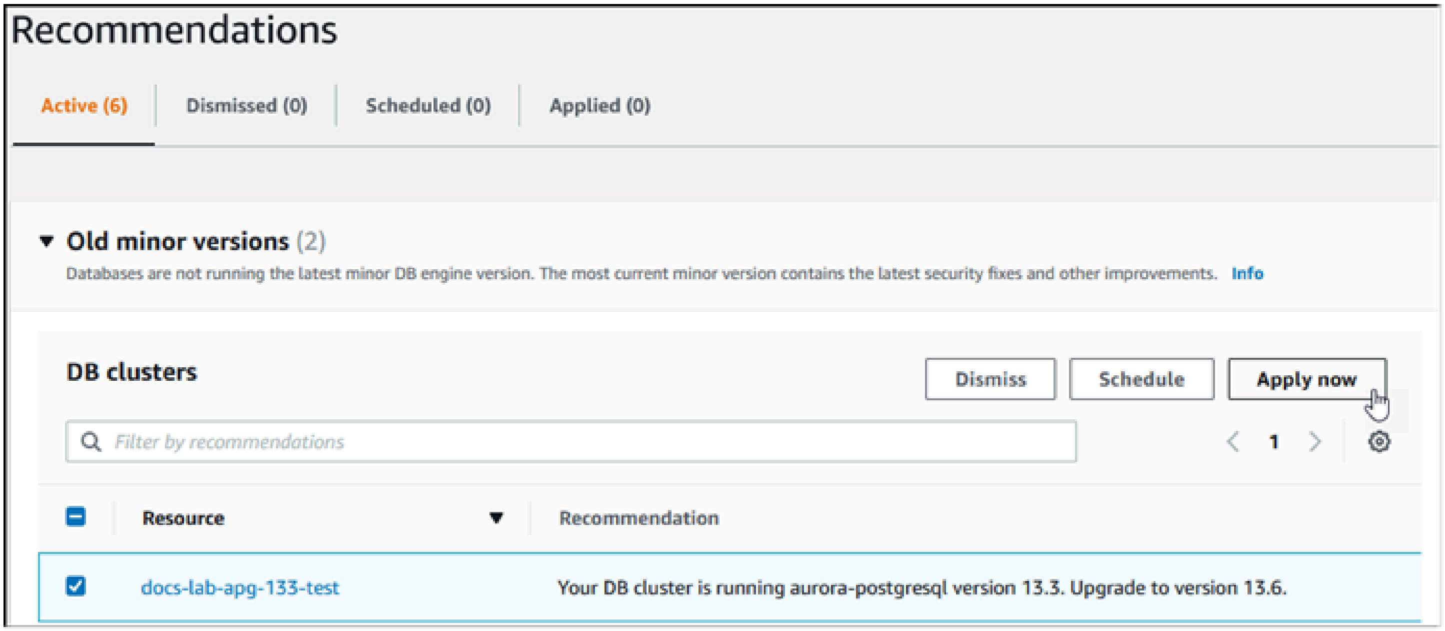
```
aws rds describe-db-instances \
  --query '*[].
{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVer
```

This query returns a list of all Aurora DB clusters and their instances with a `true` or `false` value for the status of the `AutoMinorVersionUpgrade` setting. The command as shown assumes that you have your AWS CLI configured to target your default AWS Region.

For more information about the AmVU option and how to modify your Aurora DB cluster to use it, see Automatic minor version upgrades for Aurora DB clusters.

You can upgrade your Aurora PostgreSQL DB clusters to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

You can identify any available upgrades or patches for your Aurora PostgreSQL DB clusters by using the RDS console and opening the **Recommendations** menu. There, you can find a list of various maintenance issues such as **Old minor versions**. Depending on your production environment, you can choose to **Schedule** the upgrade or take immediate action, by choosing **Apply now**, as shown following.



Databases are not running the latest minor DB engine version. The most current minor version contains the latest security fixes and other improvements.

	Resource	Recommendation
☑	docs-lab-apg-133-test	Your DB cluster is running aurora-postgresql version 13.3. Upgrade to version 13.6.

To learn more about how to maintain an Aurora DB cluster, including how to manually apply patches and minor version upgrades, see Maintaining an Amazon Aurora DB cluster.

Minor release upgrades and zero-downtime patching

Upgrading an Aurora PostgreSQL DB cluster involves the possibility of an outage. During the upgrade process, the database is shut down as it's being upgraded. If you start the upgrade while the database is busy, you lose all connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature improves the upgrading process. With ZDP, both minor version upgrades and patches can be applied with minimal impact to your Aurora PostgreSQL DB cluster. ZDP is used when applying patches or newer minor version upgrades to Aurora PostgreSQL versions and other higher releases of these minor versions and newer major versions. That is, upgrading to new minor versions from any of these releases onward uses ZDP.

The following table shows the Aurora PostgreSQL versions and DB instance classes where ZDP is available:

Version	db.r* instance classes	db.t* instance classes	db.x* instance classes	db.serverless instance class
10.21.0 and higher 10.21 versions	Yes	Yes	Yes	N/A
11.16.0 and higher 11.16 versions	Yes	Yes	Yes	N/A
11.17 and higher versions	Yes	Yes	Yes	N/A
12.11.0 and higher 12.11 versions	Yes	Yes	Yes	N/A
12.12 and higher versions	Yes	Yes	Yes	N/A

Version	db.r* instance classes	db.t* instance classes	db.x* instance classes	db.serverless instance class
13.7.0 and higher 13.7 versions	Yes	Yes	Yes	N/A
13.8 and higher versions	Yes	Yes	Yes	Yes
14.3.1 and higher 14.3 versions	Yes	Yes	Yes	N/A
14.4.0 and higher 14.4 versions	Yes	Yes	Yes	N/A
14.5 and higher versions	Yes	Yes	Yes	Yes
15.3 and higher versions	Yes	Yes	Yes	Yes

ZDP works by preserving current client connections to your Aurora PostgreSQL DB cluster throughout the Aurora PostgreSQL upgrade process. However, in the following cases, connections will be dropped for ZDP to complete:

- Long running query or transactions are in progress.
- Data definition language (DDL) statements are running.
- Temporary tables or table locks are in use.
- All sessions are listening on notification channels.
- A cursor in ‘WITH HOLD’ status is in use.
- TLSv1.3 or TLSv1.1 connections are in use.

During the upgrade process using ZDP, the database engine looks for a quiet point to pause all new transactions. This action safeguards the database during patches and upgrades. To make sure that your applications run smoothly with paused transactions, we recommend integrating retry logic into your code. This approach ensures that the system can manage any brief downtime without failing and can retry the new transactions after the upgrade.

When ZDP completes successfully, application sessions are maintained except for those with dropped connections, and the database engine restarts while the upgrade is still in progress. Although the database engine restart can cause a temporary drop in throughput, this typically lasts only for a few seconds or at most, approximately one minute.

In some cases, zero-downtime patching (ZDP) might not succeed. For example, parameter changes that are in a `pending` state on your Aurora PostgreSQL DB cluster or its instances interfere with ZDP.

You can find metrics and events for ZDP operations in **Events** page in the console. The events include the start of the ZDP upgrade and completion of the upgrade. In this event you can find how long the process took, and the numbers of preserved and dropped connections that occurred during the restart. You can find details in your database error log.

Upgrading the Aurora PostgreSQL engine to a new minor version

You can upgrade your Aurora PostgreSQL DB cluster to a new minor version by using the console, the AWS CLI, or the RDS API. Before performing the upgrade, we recommend that you follow the same best practice that we recommend for major version upgrades. As with new major versions, new minor versions can also have optimizer improvements, such as fixes, that can cause query plan regressions. To ensure plan stability, we recommend that you use the Query Plan Management (QPM) extension as detailed in Ensuring plan stability after a major version upgrade.

Console

To upgrade the engine version of your Aurora PostgreSQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.

5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon Aurora DB cluster.
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of a DB cluster, use the modify-db-cluster AWS CLI command with the following parameters:

- `--db-cluster-identifier` – The name of your Aurora PostgreSQL DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately` instead.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --engine-version new_version \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --engine-version new_version ^
    --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB cluster, use the ModifyDBCluster operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example *`mydbcluster`*.
- `EngineVersion` – The version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `ApplyImmediately` – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Upgrading PostgreSQL extensions

Upgrading your Aurora PostgreSQL DB cluster to a new major or minor version doesn't upgrade the PostgreSQL extensions at the same time. For most extensions, you upgrade the extension after the major or minor version upgrade completes. However, in some cases, you upgrade the extension before you upgrade the Aurora PostgreSQL DB engine. For more information, see the list of extensions to update in Testing an upgrade of your production DB cluster to a new major version.

Installing PostgreSQL extensions requires `rds_superuser` privileges. Typically, an `rds_superuser` delegates permissions over specific extensions to relevant users (roles), to facilitate the management of a given extension. That means that the task of upgrading all the extensions in your Aurora PostgreSQL DB cluster might involve many different users (roles). Keep this in mind especially if you want to automate the upgrade process by using scripts. For more information about PostgreSQL privileges and roles, see Security with Amazon Aurora PostgreSQL.

> **Note**
>
> For information about updating the PostGIS extension, see Managing spatial data with the PostGIS extension (Step 6: Upgrade the PostGIS extension).
> To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded DB instance. For more information, see pg_repack installation in the `pg_repack` documentation.

To update an extension after an engine upgrade, use the `ALTER EXTENSION UPDATE` command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

To list your currently installed extensions, use the PostgreSQL pg_extension catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL pg_available_extension_versions view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see *Using Blue/Green Deployments for database updates*.

Aurora PostgreSQL long-term support (LTS) releases

Each new Aurora PostgreSQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora PostgreSQL version is no longer supported.

Aurora designates certain Aurora PostgreSQL versions as long-term support (LTS) releases. Database clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. LTS minor versions include only bug fixes (through patch versions); an LTS version doesn't include new features released after its introduction.

Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

Note

To remain on an LTS minor version for the duration of its lifecycle, make sure to turn off **Auto minor version upgrade** for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set **Auto minor version upgrade** to **No** on all DB instances in your Aurora cluster.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora PostgreSQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora PostgreSQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora PostgreSQL database engine.
- The database version for your Aurora PostgreSQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora PostgreSQL are as follows:

- PostgreSQL 14.6. It was released on January 20, 2023. For more information, see PostgreSQL 14.6 in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 13.9. It was released on January 20, 2023. For more information, see PostgreSQL 13.9 in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 12.9. It was released on February 25, 2022. For more information, see PostgreSQL 12.9 in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 11.9 (Aurora PostgreSQL release 3.4. It was released on December 11, 2020. For more information about this version, see PostgreSQL 11.9, Aurora PostgreSQL release 3.4 in the *Release Notes for Aurora PostgreSQL*.

For information about how to identify Aurora and database engine versions, see Identifying versions of Amazon Aurora PostgreSQL.

Using Amazon Aurora global databases

Amazon Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. An Aurora global database has a primary DB cluster in one Region, and up to five secondary DB clusters in different Regions.

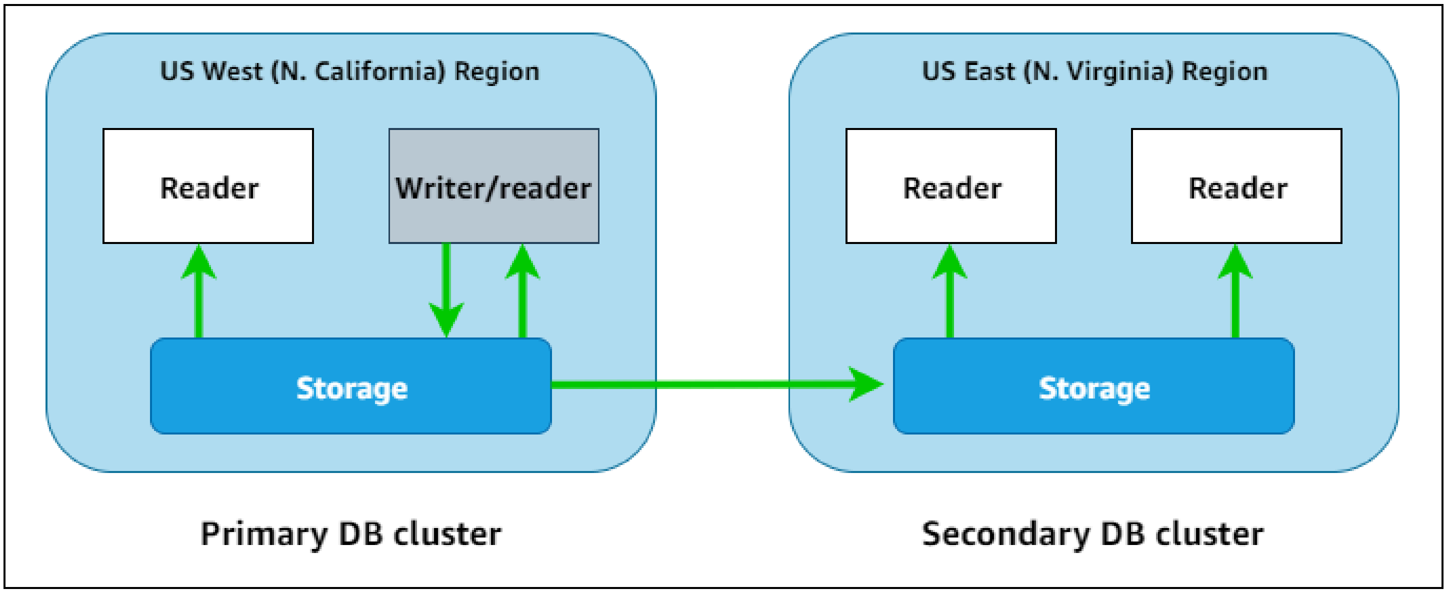
Topics

Overview of Amazon Aurora global databases

By using an Amazon Aurora global database, you can run your globally distributed applications using a single Aurora database that spans multiple AWS Regions.

An Aurora global database consists of one *primary* AWS Region where your data is written, and up to five read-only *secondary* AWS Regions. You issue write operations directly to the primary DB cluster in the primary AWS Region. Aurora replicates data to the secondary AWS Regions using dedicated infrastructure, with latency typically under a second.

In the following diagram, you can find an example Aurora global database that spans two AWS Regions.



You can scale up each secondary cluster independently, by adding one or more Aurora Replicas (read-only Aurora DB instances) to serve read-only workloads.

Only the primary cluster performs write operations. Clients that perform write operations connect to the DB cluster endpoint of the primary DB cluster. As shown in the diagram, Aurora global database uses the cluster storage volume and not the database engine for replication. To learn more, see Overview of Amazon Aurora storage.

Aurora global databases are designed for applications with a worldwide footprint. The read-only secondary DB clusters (AWS Regions) allow you to support read operations closer to application users. By using the write forwarding feature, you can also configure an Aurora global database so that secondary clusters send data to the primary. For more information, see Using write forwarding in an Amazon Aurora global database.

An Aurora global database supports two different operations for changing the Region of your primary DB cluster, depending on the scenario: *global database switchover* and *global database failover*.

- For planned operational procedures such as Regional rotation, use *global database switchover* (previously called "managed planned failover"). With this feature, you can relocate the primary cluster of a healthy Aurora global database to one of its secondary Regions with no data loss. To learn more, see Performing switchovers for Amazon Aurora global databases.
- To recover your Aurora global database after an outage in the primary Region, use *global database failover*. With this feature, you fail over your primary DB cluster to another Region

(cross-Region failover). To learn more, see Performing managed failovers for Aurora global databases.

Advantages of Amazon Aurora global databases

By using Aurora global databases, you can get the following advantages:

- **Global reads with local latency –** If you have offices around the world, you can use an Aurora global database to keep your main sources of information updated in the primary AWS Region. Offices in your other Regions can access the information in their own Region, with local latency.
- **Scalable secondary Aurora DB clusters –** You can scale your secondary clusters by adding more read-only instances (Aurora Replicas) to a secondary AWS Region. The secondary cluster is read-only, so it can support up to 16 read-only Aurora Replica instances rather than the usual limit of 15 for a single Aurora cluster.
- **Fast replication from primary to secondary Aurora DB clusters –** The replication performed by an Aurora global database has little performance impact on the primary DB cluster. The resources of the DB instances are fully devoted to serve application read and write workloads.
- **Recovery from Region-wide outages –** The secondary clusters allow you to make an Aurora global database available in a new primary AWS Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.

Region and version availability

Feature availability and support vary across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and global databases, see Supported Regions and DB engines for Aurora global databases.

Limitations of Amazon Aurora global databases

The following limitations currently apply to Aurora global databases:

- Aurora global databases are available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see Supported Regions and DB engines for Aurora global databases.

- Aurora global databases have specific configuration requirements for supported Aurora DB instance classes, maximum number of AWS Regions, and so on. For more information, see Configuration requirements of an Amazon Aurora global database.
- For Aurora MySQL with MySQL 5.7 compatibility, Aurora global database switchovers require version 2.09.1 or a higher minor version.
- You can perform managed cross-Region switchovers or failovers on an Aurora global database only if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different if the minor engine versions are one of the following.

Database engine	Minor engine versions
Aurora PostgreSQL	• Version 14.5 or higher minor version • Version 13.8 or higher minor version • Version 12.12 or higher minor version • Version 11.17 or higher minor version

  For more information, see Patch level compatibility for managed cross-Region switchovers and failovers.
- Aurora global databases currently don't support the following Aurora features:
  - Aurora Serverless v1
  - Backtracking in Aurora
- For limitations with using the RDS Proxy feature with global databases, see Limitations for RDS Proxy with global databases.
- Automatic minor version upgrade doesn't apply to Aurora MySQL and Aurora PostgreSQL clusters that are part of an Aurora global database. Note that you can specify this setting for a DB instance that is part of a global database cluster, but the setting has no effect.
- Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.
- To use database activity streams on Aurora global databases running Aurora MySQL 5.7, the engine version must be version 2.08 or higher. For information about database activity streams, see Monitoring Amazon Aurora with Database Activity Streams.
- The following limitations currently apply to upgrading Aurora global databases:

  - You can't apply a custom parameter group to the global database cluster while you're performing a major version upgrade of that Aurora global database. You create your custom parameter groups in each Region of the global cluster and you apply them manually to the Regional clusters after the upgrade.
  - With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on. For more information on the methods that you can use, see Major version upgrades.
  - With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see Managing RPOs for Aurora PostgreSQL–based global databases.
  - With an Aurora global database based on Aurora MySQL, you can't perform a minor version upgrade from version 3.01 or 3.02 to 3.03 or higher by using the standard process. For details about the process to use, see Upgrading Aurora MySQL by modifying the engine version.

  For information about upgrading an Aurora global database, see Upgrading an Amazon Aurora global database.

- You can't stop or start the Aurora DB clusters in your Aurora global database individually. To learn more, see Stopping and starting an Amazon Aurora DB cluster.
- Aurora Replicas attached to the secondary Aurora DB cluster can restart under certain circumstances. If the primary AWS Region's writer DB instance restarts or fails over, Aurora Replicas in secondary Regions also restart. The secondary cluster is then unavailable until all replicas are back in sync with the primary DB cluster's writer instance. The behavior of the primary cluster when rebooting or failing over is the same as for a singular, nonglobal DB cluster. For more information, see Replication with Amazon Aurora.

  Be sure that you understand the impacts to your Aurora global database before making changes to your primary DB cluster. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage.
- Aurora global databases currently don't support the `inaccessible-encryption-credentials-recoverable` status when Amazon Aurora loses access to the AWS KMS key for the DB cluster. In these cases, the encrypted DB cluster goes directly into the terminal `inaccessible-encryption-credentials` state. For more information about these states, see Viewing DB cluster status.

- Aurora PostgreSQL–based DB clusters running in an Aurora global database have the following limitations:
  - Cluster cache management isn't supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.
  - If the primary DB cluster of your Aurora global database is based on a replica of an Amazon RDS PostgreSQL instance, you can't create a secondary cluster. Don't attempt to create a secondary from that cluster using the AWS Management Console, the AWS CLI, or the `CreateDBCluster` API operation. Attempts to do so time out, and the secondary cluster isn't created.

We recommend that you create secondary DB clusters for your Aurora global databases by using the same version of the Aurora DB engine as the primary. For more information, see Creating an Amazon Aurora global database.

Getting started with Amazon Aurora global databases

To get started with Aurora global databases, first decide which Aurora DB engine you want to use and in which AWS Regions. Only specific versions of the Aurora MySQL and Aurora PostgreSQL database engines in certain AWS Regions support Aurora global databases. For the complete list, see Supported Regions and DB engines for Aurora global databases.

You can create an Aurora global database in one of the following ways:

- **Create a new Aurora global database with new Aurora DB clusters and Aurora DB instances** – You can do this by following the steps in Creating an Amazon Aurora global database. After you create the primary Aurora DB cluster, you then add the secondary AWS Region by following the steps in Adding an AWS Region to an Amazon Aurora global database.
- **Use an existing Aurora DB cluster that supports the Aurora global database feature and add an AWS Region to it** – You can do this only if your existing Aurora DB cluster uses a DB engine version that supports the Aurora global mode or is global-compatible. For some DB engine versions, this mode is explicit, but for others, it's not.

  Check whether you can choose **Add region** for **Action** on the AWS Management Console when your Aurora DB cluster is selected. If you can, you can use that Aurora DB cluster for your Aurora global cluster. For more information, see Adding an AWS Region to an Amazon Aurora global database.

Before creating an Aurora global database, we recommend that you understand all configuration requirements.

Topics

Configuration requirements of an Amazon Aurora global database

An Aurora global database spans at least two AWS Regions. The primary AWS Region supports an Aurora DB cluster that has one writer Aurora DB instance. A secondary AWS Region runs a read-only Aurora DB cluster made up entirely of Aurora Replicas. At least one secondary AWS Region is required, but an Aurora global database can have up to five secondary AWS Regions. The table lists the maximum Aurora DB clusters, Aurora DB instances, and Aurora Replicas allowed in an Aurora global database.

Description	Primary AWS Region	Secondary AWS Regions
Aurora DB clusters	1	5 (maximum)
Writer instances	1	0
Read-only instances (Aurora replicas), per Aurora DB cluster	15 (max)	16 (total)
Read-only instances (max allowed, given actual number of secondary Regions)	15 - *s*	*s* = total number of secondary AWS Regions

The Aurora DB clusters that make up an Aurora global database have the following specific requirements:

- **DB instance class requirements –** An Aurora global database requires DB instance classes that are optimized for memory-intensive applications. For information about the memory optimized DB instance classes, see DB instance classes. We recommend that you use a db.r5 or higher instance class.
- **AWS Region requirements –** An Aurora global database needs a primary Aurora DB cluster in one AWS Region, and at least one secondary Aurora DB cluster in a different Region. You can create up to five secondary (read-only) Aurora DB clusters, and each must be in a different Region. In other words, no two Aurora DB clusters in an Aurora global database can be in the same AWS Region.
- **Naming requirements –** The names you choose for each of your Aurora DB clusters must be unique, across all AWS Regions. You can't use the same name for different Aurora DB clusters even though they're in different Regions.
- **Capacity requirements for Aurora Serverless v2 –** For a global database with Aurora Serverless v2, the minimum capacity required for the DB cluster in the primary AWS Region is 8 ACUs.

Before you can follow the procedures in this section, you need an AWS account. Complete the setup tasks for working with Amazon Aurora. For more information, see Setting up your environment for Amazon Aurora. You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see Creating an Amazon Aurora DB cluster.

Creating an Amazon Aurora global database

In some cases, you might have an existing Aurora provisioned DB cluster running an Aurora database engine that's global-compatible. If so, you can add another AWS Region to it to create your Aurora global database. To do so, see Adding an AWS Region to an Amazon Aurora global database.

To create an Aurora global database by using the AWS Management Console, the AWS CLI, or the RDS API, use the following steps.

Console

The steps for creating an Aurora global database begin by signing in to an AWS Region that supports the Aurora global database feature. For a complete list, see Supported Regions and DB engines for Aurora global databases.

One of the following steps is choosing a virtual private cloud (VPC) based on Amazon VPC for your Aurora DB cluster. To use your own VPC, we recommend that you create it in advance so it's available for you to choose. At the same time, create any related subnets, and as needed a subnet group and security group. To learn how, see Tutorial: Create an Amazon VPC for use with a DB instance.

For general information about creating an Aurora DB cluster, see Creating an Amazon Aurora DB cluster.

To create an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Create database**. On the **Create database** page, do the following:

   - For the database creation method, choose **Standard create**. (Don't choose Easy create.)
   - For `Engine type` in the **Engine options** section, choose the applicable engine type, **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.
3. Continue creating your Aurora global database by using the steps from the following procedures.

Creating a global database using Aurora MySQL

The following steps apply to all versions of Aurora MySQL.

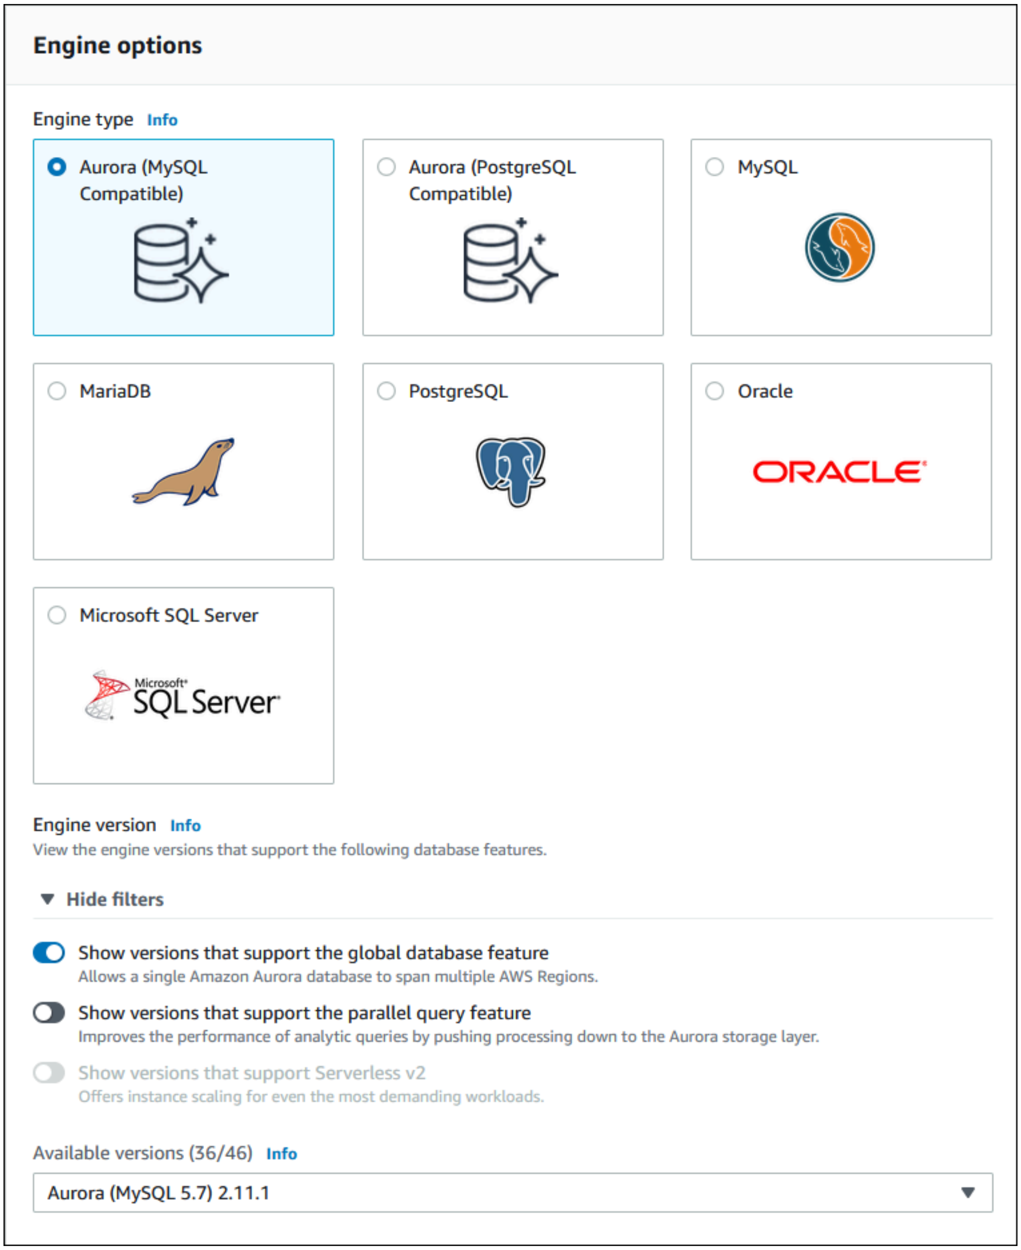
To create an Aurora global database using Aurora MySQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:

   a. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.

   b. For **Engine version**, choose the version of Aurora MySQL that you want to use for your Aurora global database.



Engine options

Engine type Info

● Aurora (MySQL Compatible)

○ Aurora (PostgreSQL Compatible)

○ MySQL

○ MariaDB

○ PostgreSQL

○ Oracle

○ Microsoft SQL Server

Engine version Info

View the engine versions that support the following database features.

▼ Hide filters

Show versions that support the global database feature: on

Allows a single Amazon Aurora database to span multiple AWS Regions.

Show versions that support the parallel query feature: off

Improves the performance of analytic queries by pushing processing down to the Aurora storage layer.

Show versions that support Serverless v2: off (unavailable)

Offers instance scaling for even the most demanding workloads.

Available versions (36/46) Info

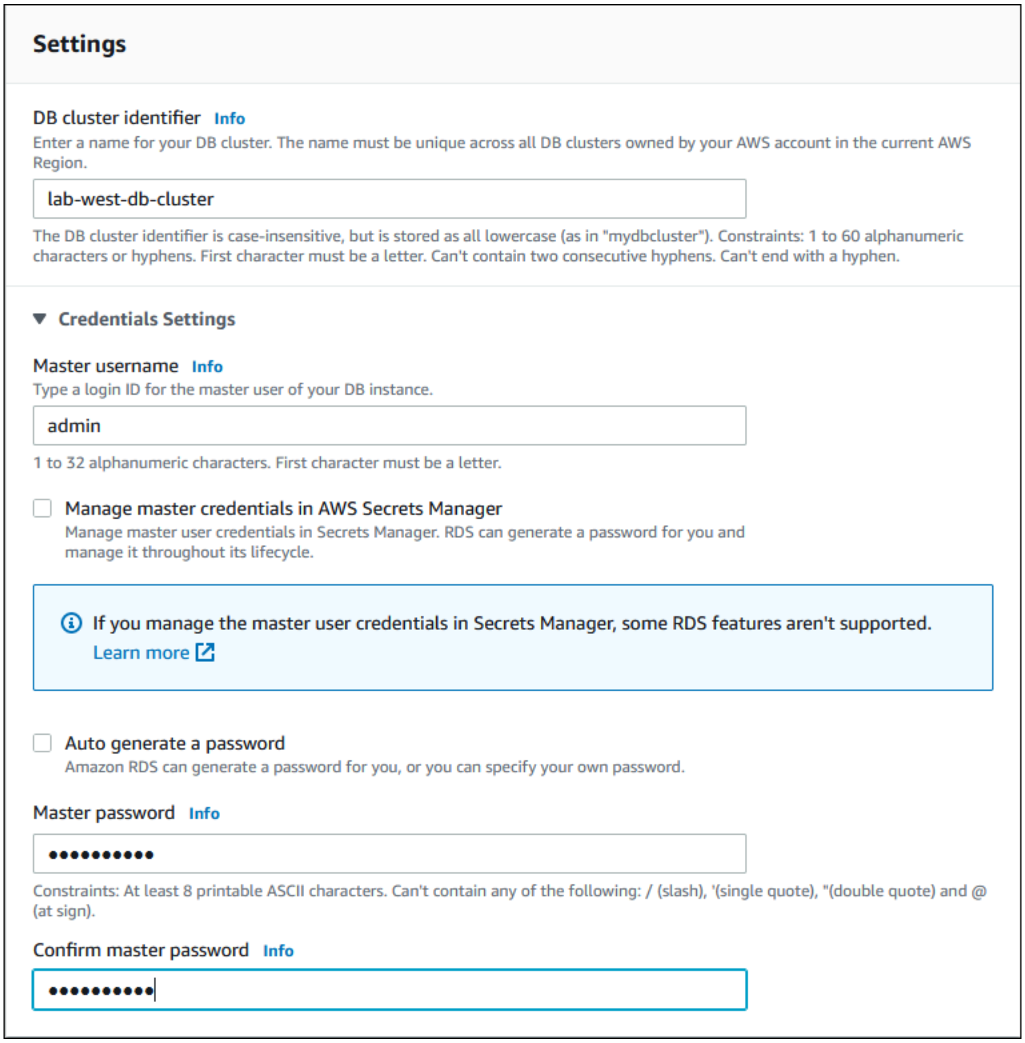
Aurora (MySQL 5.7) 2.11.1

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate for your use case. Don't use Dev/Test in production environments.

3. For **Settings**, do the following:

   a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.

   b. Enter your own password for the `admin` user account for the DB instance, or have Aurora generate one for you. If you choose to autogenerate a password, you get an option to copy the password.



Settings

DB cluster identifier Info

Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

lab-west-db-cluster

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username Info

Type a login ID for the master user of your DB instance.

admin

1 to 32 alphanumeric characters. First character must be a letter.

□ Manage master credentials in AWS Secrets Manager
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

ⓘ If you manage the master user credentials in Secrets Manager, some RDS features aren't supported.
Learn more

□ Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password.

Master password Info

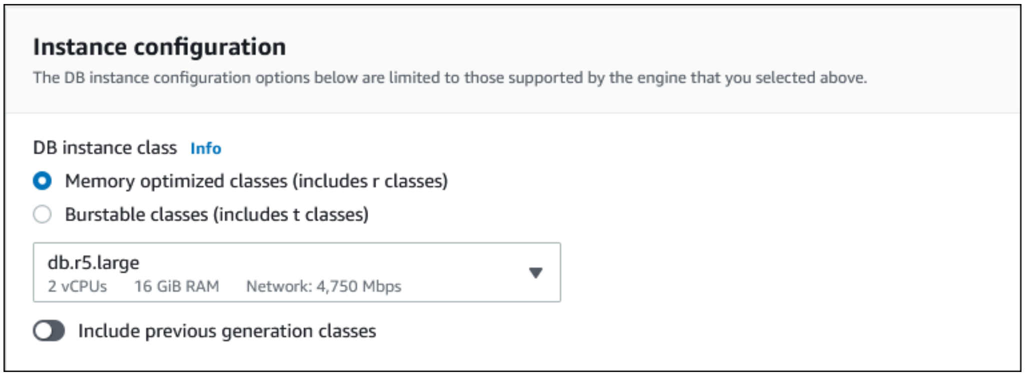
••••••••••

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm master password Info

••••••••••

4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a db.r5 or higher instance class.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

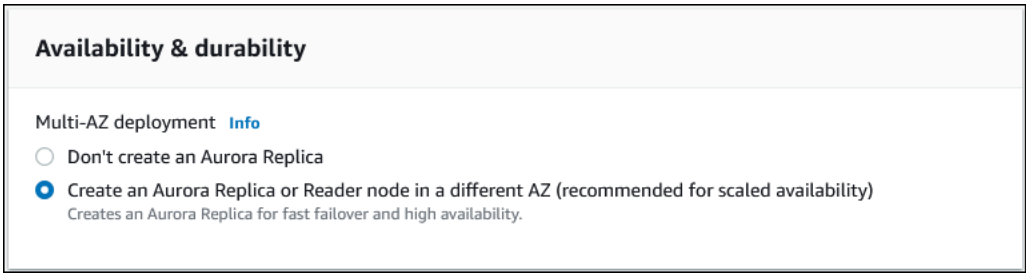
● Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

db.r5.large
2 vCPUs 16 GiB RAM Network: 4,750 Mbps

Include previous generation classes

5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different Availability Zone (AZ) for you. If you don't create an Aurora Replica now, you need to do it later.



Availability & durability

Multi-AZ deployment Info

○ Don't create an Aurora Replica

● Create an Aurora Replica or Reader node in a different AZ (recommended for scaled availability)
Creates an Aurora Replica for fast failover and high availability.

6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
7. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up AWS Identity and Access Management (IAM) later.
8. For **Additional configuration**, do the following:

   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

   b. Clear the **Enable backtrack** check box if it's selected. Aurora global databases don't support backtracking. Otherwise, accept the other default settings for **Additional configuration**.
9. Choose **Create database**.

   It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

	DB identifier	Role	Engine	Region & AZ	Size	Status
○	lab-demo-db-cluster	Regional	Aurora PostgreSQL	us-west-1	1 instance	✓ Available
●	lab-west-db-cluster	Regional	Aurora MySQL	us-west-1	2 instances	✓ Available
○	lab-west-db-cluster-instance-1	Writer	Aurora MySQL	us-west-1b	db.r4.large	✓ Available
○	lab-west-db-cluster-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r4.large	✓ Available

When your primary DB cluster is available, create the Aurora global database by adding a secondary cluster to it. To do this, follow the steps in Adding an AWS Region to an Amazon Aurora global database.

Creating a global database using Aurora PostgreSQL

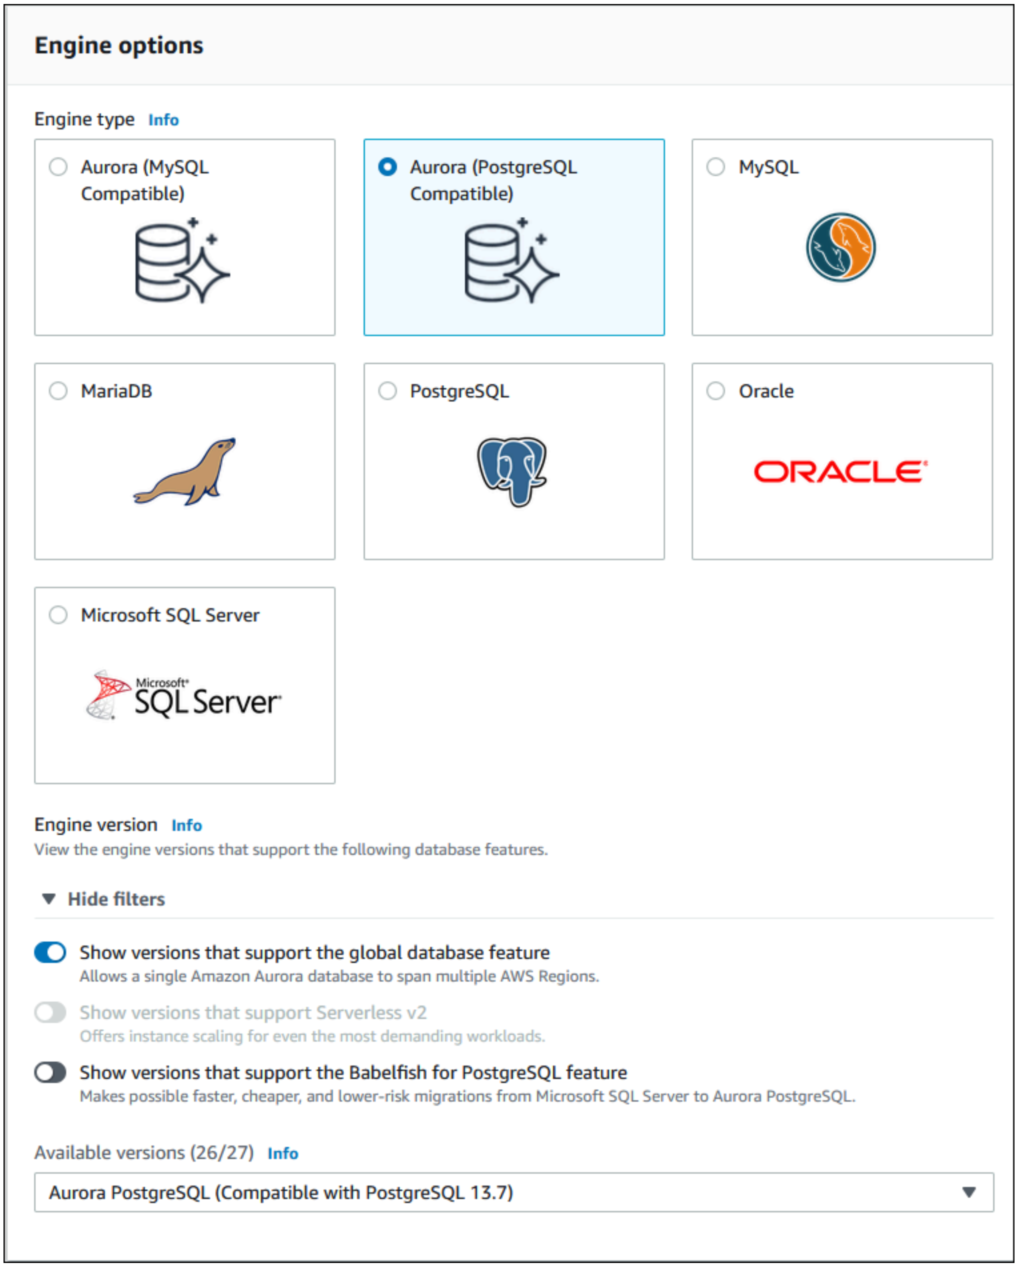
To create an Aurora global database using Aurora PostgreSQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:

   a. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.

   b. For **Engine version**, choose the version of Aurora PostgreSQL that you want to use for your Aurora global database.



Engine options

Engine type Info

○ Aurora (MySQL Compatible)

● Aurora (PostgreSQL Compatible)

○ MySQL

○ MariaDB

○ PostgreSQL

○ Oracle

○ Microsoft SQL Server

Engine version Info

View the engine versions that support the following database features.

▼ Hide filters

Show versions that support the global database feature (on)
Allows a single Amazon Aurora database to span multiple AWS Regions.

Show versions that support Serverless v2 (off, disabled)
Offers instance scaling for even the most demanding workloads.

Show versions that support the Babelfish for PostgreSQL feature (off)
Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

Available versions (26/27) Info

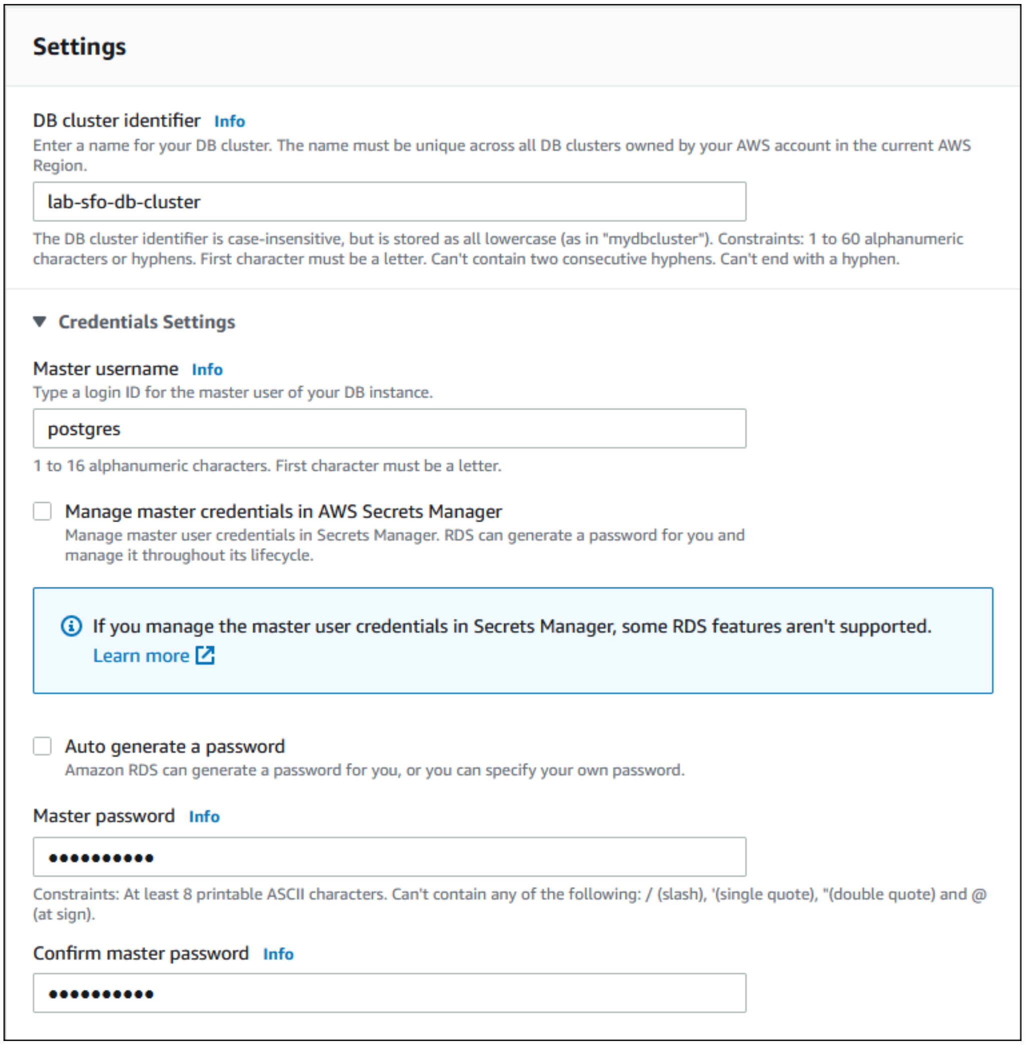
Aurora PostgreSQL (Compatible with PostgreSQL 13.7) ▼

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate. Don't use Dev/Test in production environments.

3. For **Settings**, do the following:

   a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.

   b. Enter your own password for the default admin account for the DB cluster, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.



Settings

DB cluster identifier Info

Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

lab-sfo-db-cluster

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username Info

Type a login ID for the master user of your DB instance.

postgres

1 to 16 alphanumeric characters. First character must be a letter.

□ Manage master credentials in AWS Secrets Manager

Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

ⓘ If you manage the master user credentials in Secrets Manager, some RDS features aren't supported.
Learn more

□ Auto generate a password

Amazon RDS can generate a password for you, or you can specify your own password.

Master password Info

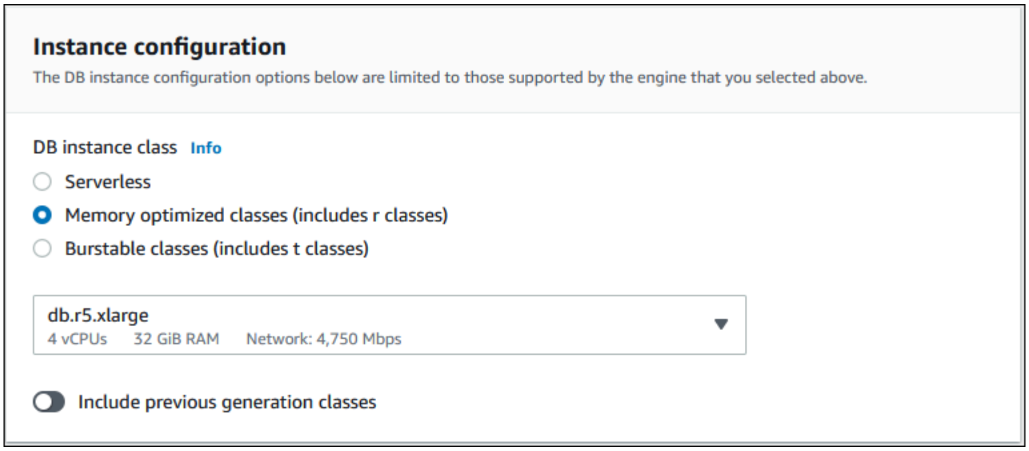
••••••••••

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm master password Info

••••••••••

4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a db.r5 or higher instance class.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

○ Serverless

● Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

db.r5.xlarge
4 vCPUs 32 GiB RAM Network: 4,750 Mbps

Include previous generation classes

5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
7. (Optional) Complete the **Database authentication** settings. Password authentication is always enabled. To simplify the process, you can skip this section and set up IAM or password and Kerberos authentication later.
8. For **Additional configuration**, do the following:

   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

   b. Accept all other default settings for **Additional configuration**, such as Encryption, Log exports, and so on.
9. Choose **Create database**.

   It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. When the cluster is ready to use, the Aurora DB cluster and its writer and replica nodes display **Available** status. This becomes the primary DB cluster of your Aurora global database, after you add a secondary.

	DB identifier ▲	Role	Engine	ize	Status
●	lab-sfo-db-cluster	Regional	Aurora Po	instances	Available
○	lab-sfo-db-cluster-instance-1	Writer	Aurora Po	b.r4.large	Available
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora Po	b.r4.large	Available
○	lab-west-db-cluster	Regional	Aurora My	instances	Available
○	lab-west-db-cluster-instance-1	Writer	Aurora My	b.r4.large	Available
○	lab-west-db-cluster-instance-1-us-west-1c	Reader	Aurora My	b.r4.large	Available

When your primary DB cluster is available, create one or more secondary clusters by following the steps in Adding an AWS Region to an Amazon Aurora global database.

AWS CLI

The AWS CLI commands in the procedures following accomplish the following tasks:

1. Create an Aurora global database, giving it a name and specifying the Aurora database engine type that you plan to use.
2. Create an Aurora DB cluster for the Aurora global database.
3. Create the Aurora DB instance for the cluster. This is the primary Aurora DB cluster for the global database.
4. Create a second DB instance for Aurora DB cluster. This is a reader to complete the Aurora DB cluster.
5. Create a second Aurora DB cluster in another Region and then add it to your Aurora global database, by following the steps in Adding an AWS Region to an Amazon Aurora global database.

Follow the procedure for your Aurora database engine.

Creating a global database using Aurora MySQL

To create an Aurora global database using Aurora MySQL

1. Use the create-global-cluster CLI command, passing the name of the AWS Region, Aurora database engine, and version.

   For Linux, macOS, or Unix:

   ```
   aws rds create-global-cluster --region primary_region  \
       --global-cluster-identifier global_database_id \
       --engine aurora-mysql \
       --engine-version version # optional
   ```

   For Windows:

   ```
   aws rds create-global-cluster ^
       --global-cluster-identifier global_database_id ^
       --engine aurora-mysql ^
       --engine-version version # optional
   ```

   This creates an "empty" Aurora global database, with just a name (identifier) and Aurora database engine. It can take a few minutes for the Aurora global database to be available. Before going to the next step, use the describe-global-clusters CLI command to see if it's available.

   ```
   aws rds describe-global-clusters --region primary_region --global-cluster-
   identifier global_database_id
   ```

   When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the create-db-cluster CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-cluster \
     --region primary_region \
     --db-cluster-identifier primary_db_cluster_id \
   ```

```
  --master-username userid \
  --master-user-password password \
  --engine aurora-mysql \
  --engine-version version \
  --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^
  --region primary_region ^
  --db-cluster-identifier primary_db_cluster_id ^
  --master-username userid ^
  --master-user-password password ^
  --engine aurora-mysql ^
  --engine-version version ^
  --global-cluster-identifier global_database_id
```

Use the `describe-db-clusters` AWS CLI command to confirm that the Aurora DB cluster is ready. To single out a specific Aurora DB cluster, use `--db-cluster-identifier` parameter. Or you can leave out the Aurora DB cluster name in the command to get details about all your Aurora DB clusters in the given Region.

```
aws rds describe-db-clusters --region primary_region --db-cluster-
identifier primary_db_cluster_id
```

When the response shows `"Status": "available"` for the cluster, it's ready to use.

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the `create-db-instance` CLI command. Give the command your Aurora DB cluster's name, and specify the configuration details for the instance. You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

   For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a db.r5 or higher instance class. For information about these classes, see DB instance classes.

   For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier db_instance_id \
  --engine aurora-mysql \
  --engine-version version \
  --region primary_region
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
  --db-instance-class instance_class ^
  --db-instance-identifier db_instance_id ^
  --engine aurora-mysql ^
  --engine-version version ^
  --region primary_region
```

The `create-db-instance` operation might take some time to complete. Check the status to see if the Aurora DB instance is available before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```

When the command returns a status of "available," you can create another Aurora DB instance for your primary DB cluster. This is the reader instance (the Aurora Replica) for the Aurora DB cluster.

4. To create another Aurora DB instance for the cluster, use the [`create-db-instance`] CLI command.

   For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier replica_db_instance_id \
  --engine aurora-mysql
```

   For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
```

```
    --db-instance-class instance_class ^
    --db-instance-identifier replica_db_instance_id ^
    --engine aurora-mysql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

At this point, you have an Aurora global database with its primary Aurora DB cluster containing a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in Adding an AWS Region to an Amazon Aurora global database.

Creating a global database using Aurora PostgreSQL

When you create Aurora objects for an Aurora global database by using the following commands, it can take a few minutes for each to become available. We recommend that after completing any given command, you check the specific Aurora object's status to make sure that the status is available.

To do so, use the `describe-global-clusters` CLI command.

```
aws rds describe-global-clusters --region primary_region
    --global-cluster-identifier global_database_id
```

To create an Aurora global database using Aurora PostgreSQL

1. Use the `create-global-cluster` CLI command.

   For Linux, macOS, or Unix:

   ```
   aws rds create-global-cluster --region primary_region  \
       --global-cluster-identifier global_database_id \
       --engine aurora-postgresql \
       --engine-version version # optional
   ```

   For Windows:

   ```
   aws rds create-global-cluster ^
       --global-cluster-identifier global_database_id ^
   ```

```
    --engine aurora-postgresql ^
    --engine-version version # optional
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the `create-db-cluster` CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-cluster \
     --region primary_region \
     --db-cluster-identifier primary_db_cluster_id \
     --master-username userid \
     --master-user-password password \
     --engine aurora-postgresql \
     --engine-version version \
     --global-cluster-identifier global_database_id
   ```

   For Windows:

   ```
   aws rds create-db-cluster ^
     --region primary_region ^
     --db-cluster-identifier primary_db_cluster_id ^
     --master-username userid ^
     --master-user-password password ^
     --engine aurora-postgresql ^
     --engine-version version ^
     --global-cluster-identifier global_database_id
   ```

   Check that the Aurora DB cluster is ready. When the response from the following command shows `"Status": "available"` for the Aurora DB cluster, you can continue.

   ```
   aws rds describe-db-clusters --region primary_region --db-cluster-
   identifier primary_db_cluster_id
   ```

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the `create-db-instance` CLI command.

   Pass the name of your Aurora DB cluster with the `--db-cluster-identifier` parameter.

You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a db.r5 or higher instance class. For information about these classes, see DB instance classes.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier db_instance_id \
  --engine aurora-postgresql \
  --engine-version version \
  --region primary_region
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
  --db-instance-class instance_class ^
  --db-instance-identifier db_instance_id ^
  --engine aurora-postgresql ^
  --engine-version version ^
  --region primary_region
```

4. Check the status of the Aurora DB instance before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```

If the response shows that Aurora DB instance status is "available," you can create another Aurora DB instance for your primary DB cluster.

5. To create an Aurora Replica for Aurora DB cluster, use the `create-db-instance` CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier replica_db_instance_id \
  --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
  --db-instance-class instance_class ^
  --db-instance-identifier replica_db_instance_id ^
  --engine aurora-postgresql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

Your Aurora global database exists, but it has only its primary Region with an Aurora DB cluster made up of a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in Adding an AWS Region to an Amazon Aurora global database.

RDS API

To create an Aurora global database with the RDS API, run the CreateGlobalCluster operation.

Adding an AWS Region to an Amazon Aurora global database

An Aurora global database needs at least one secondary Aurora DB cluster in a different AWS Region than the primary Aurora DB cluster. You can attach up to five secondary DB clusters to your Aurora global database. For each secondary DB cluster that you add to your Aurora global database, reduce the number of Aurora Replicas allowed to the primary DB cluster by one.

For example, if your Aurora global database has 5 secondary Regions, your primary DB cluster can have only 10 (rather than 15) Aurora Replicas. For more information, see Configuration requirements of an Amazon Aurora global database.

The number of Aurora Replicas (reader instances) in the primary DB cluster determines the number of secondary DB clusters you can add. The total number of reader instances in the primary DB cluster plus the number of secondary clusters can't exceed 15. For example, if you have 14 reader instances in the primary DB cluster and 1 secondary cluster, you can't add another secondary cluster to the global database.

> **Note**
>
> For Aurora MySQL version 3, when you create a secondary cluster, make sure that the value of `lower_case_table_names` matches the value in the primary cluster. This setting is a database parameter that affects how the server handles identifier case sensitivity. For more information about database parameters, see Working with parameter groups.
>
> We recommend that when you create a secondary cluster, you use the same DB engine version for the primary and secondary. If necessary, upgrade the primary to be the same version as the secondary. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers.

Console

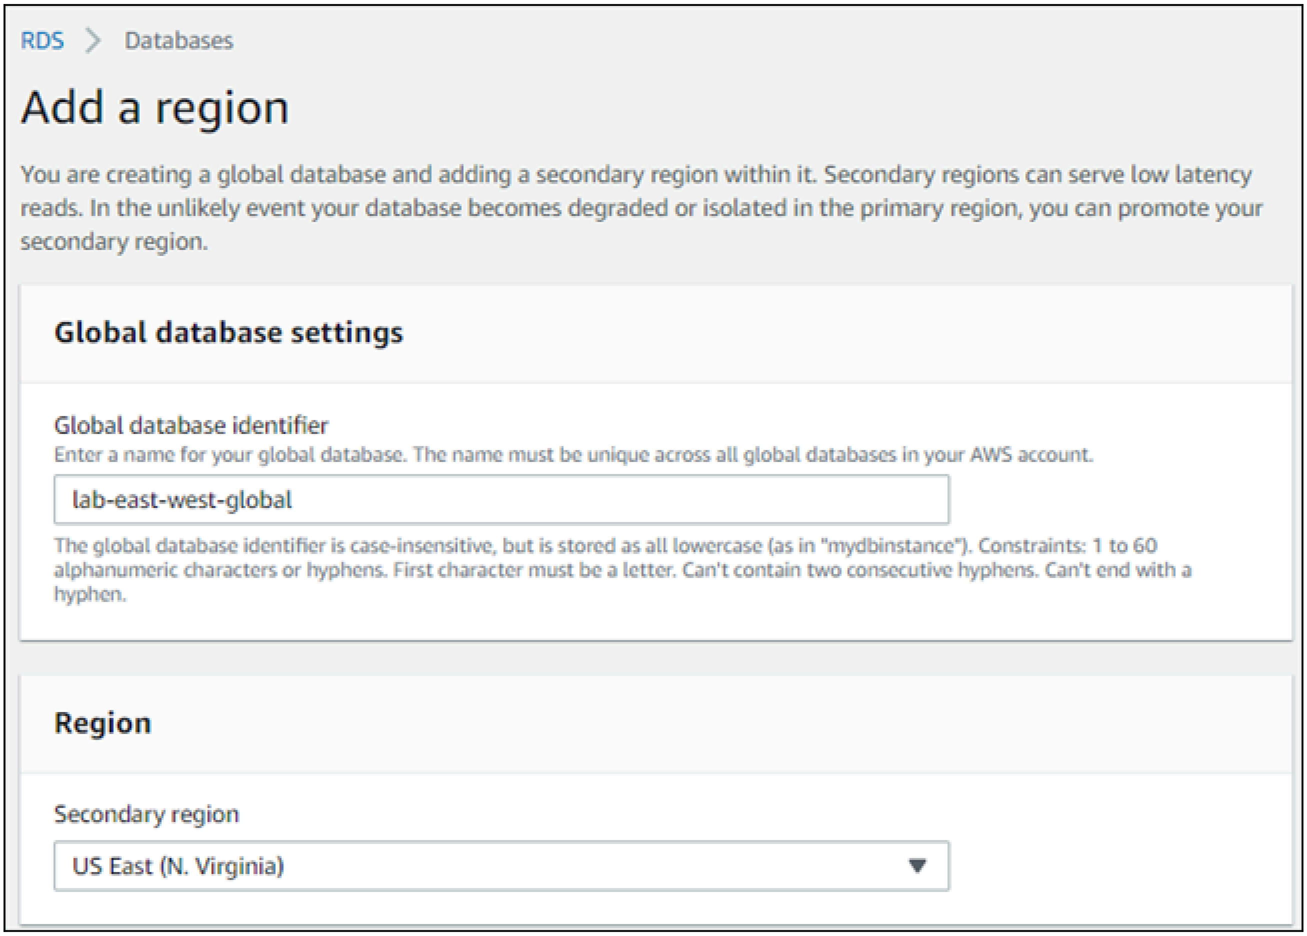
To add an AWS Region to an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane of the AWS Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is `Available`.
4. For **Actions**, choose **Add region**.

	DB identifier ▲	Role	Engine	ize	Status
●	lab-sfo-db-cluster	Regional	Aurora Po	instances	Available
○	lab-sfo-db-cluster-instance-1	Writer	Aurora Po	b.r4.large	Available
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora Po	b.r4.large	Available
○	lab-west-db-cluster	Regional	Aurora My	instances	Available
○	lab-west-db-cluster-instance-1	Writer	Aurora My	b.r4.large	Available
○	lab-west-db-cluster-instance-1-us-west-1c	Reader	Aurora My	b.r4.large	Available

5. On the **Add a region** page, choose the secondary AWS Region.

   You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.



Add a region

You are creating a global database and adding a secondary region within it. Secondary regions can serve low latency reads. In the unlikely event your database becomes degraded or isolated in the primary region, you can promote your secondary region.

Global database settings

Global database identifier
Enter a name for your global database. The name must be unique across all global databases in your AWS account.

lab-east-west-global

The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

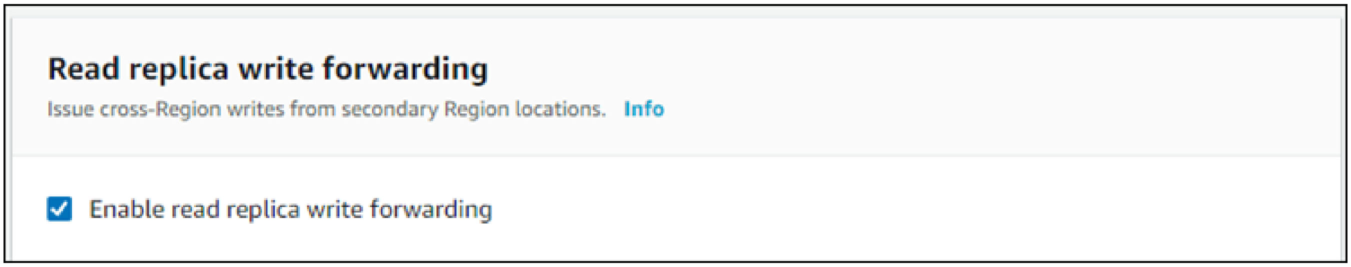
Region

Secondary region

US East (N. Virginia) ▼

6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance, except for the following option for Aurora MySQL–based Aurora global databases only:

   - Enable read replica write forwarding – This optional setting let's your Aurora global database's secondary DB clusters forward write operations to the primary cluster. For more information, see [Using write forwarding in an Amazon Aurora global database](#).



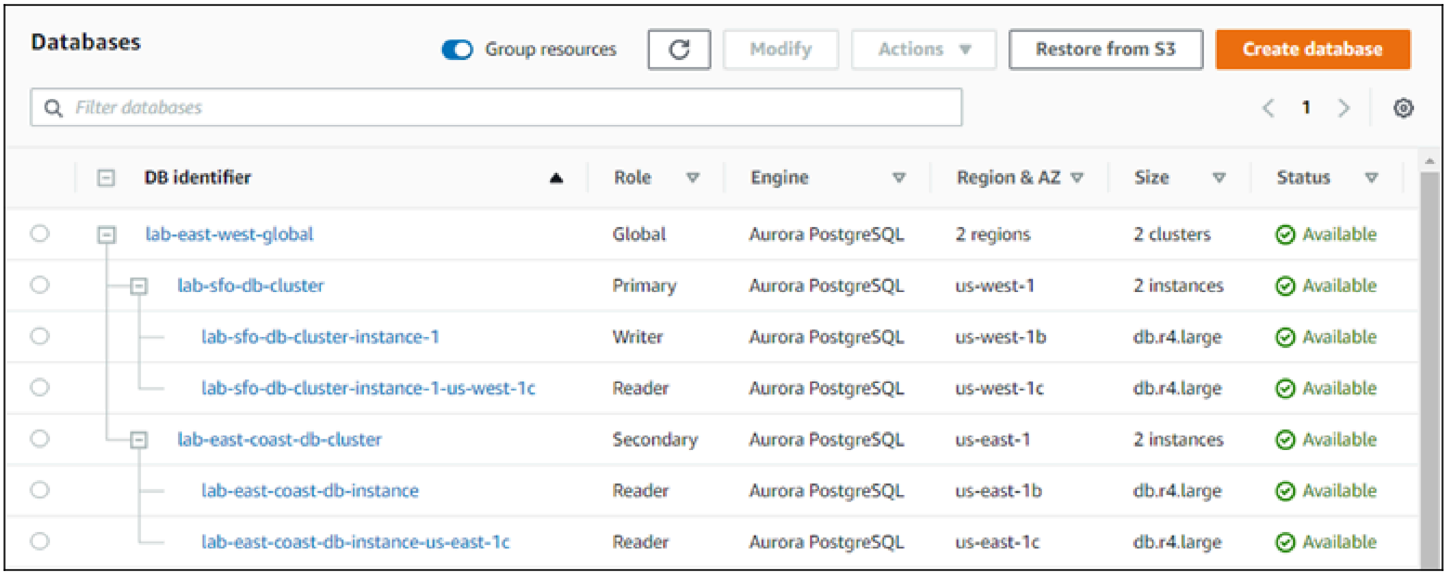
Read replica write forwarding

Issue cross-Region writes from secondary Region locations. Info

☑ Enable read replica write forwarding

7. Choose **Add region**.

After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the AWS Management Console as shown in the screenshot.



DB identifier	Role	Engine	Region & AZ	Size	Status
lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters	Available
lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	Available
lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	Available
lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	Available
lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	Available
lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large	Available
lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	Available

AWS CLI

To add a secondary AWS Region to an Aurora global database

1. Use the [`create-db-cluster`](#) CLI command with the name (`--global-cluster-identifier`) of your Aurora global database. For other parameters, do the following:

2. For `--region`, choose a different AWS Region than that of your Aurora primary Region.

3. Choose specific values for the `--engine` and `--engine-version` parameters. These values are the same as those for the primary Aurora DB cluster in your Aurora global database.
4. For an encrypted cluster, specify your primary AWS Region as the `--source-region` for encryption.

The following example creates a new Aurora DB cluster and attaches it to an Aurora global database as a read-only secondary Aurora DB cluster. In the last step, an Aurora DB instance is added to the new Aurora DB cluster.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
  create-db-cluster \
    --db-cluster-identifier secondary_cluster_id \
    --global-cluster-identifier global_database_id \
    --engine aurora-mysql|aurora-postgresql
    --engine-version version

aws rds --region secondary_region \
  create-db-instance \
    --db-instance-class instance_class \
    --db-cluster-identifier secondary_cluster_id \
    --db-instance-identifier db_instance_id \
    --engine aurora-mysql|aurora-postgresql
```

For Windows:

```
aws rds --region secondary_region ^
  create-db-cluster ^
    --db-cluster-identifier secondary_cluster_id ^
    --global-cluster-identifier global_database_id_id ^
    --engine aurora-mysql|aurora-postgresql ^
    --engine-version version

aws rds --region secondary_region ^
  create-db-instance ^
    --db-instance-class instance_class ^
    --db-cluster-identifier secondary_cluster_id ^
    --db-instance-identifier db_instance_id ^
    --engine aurora-mysql|aurora-postgresql
```

RDS API

To add a new AWS Region to an Aurora global database with the RDS API, run the CreateDBCluster operation. Specify the identifier of the existing global database using the `GlobalClusterIdentifier` parameter.

Creating a headless Aurora DB cluster in a secondary Region

Although an Aurora global database requires at least one secondary Aurora DB cluster in a different AWS Region than the primary, you can use a *headless* configuration for the secondary cluster. A headless secondary Aurora DB cluster is one without a DB instance. This type of configuration can lower expenses for an Aurora global database. In an Aurora DB cluster, compute and storage are decoupled. Without the DB instance, you're not charged for compute, only for storage. If it's set up correctly, a headless secondary's storage volume is kept in-sync with the primary Aurora DB cluster.

You add the secondary cluster as you normally do when creating an Aurora global database. However, after the primary Aurora DB cluster begins replication to the secondary, you delete the Aurora read-only DB instance from the secondary Aurora DB cluster. This secondary cluster is now considered "headless" because it no longer has a DB instance. Yet, the storage volume is kept in sync with the primary Aurora DB cluster.

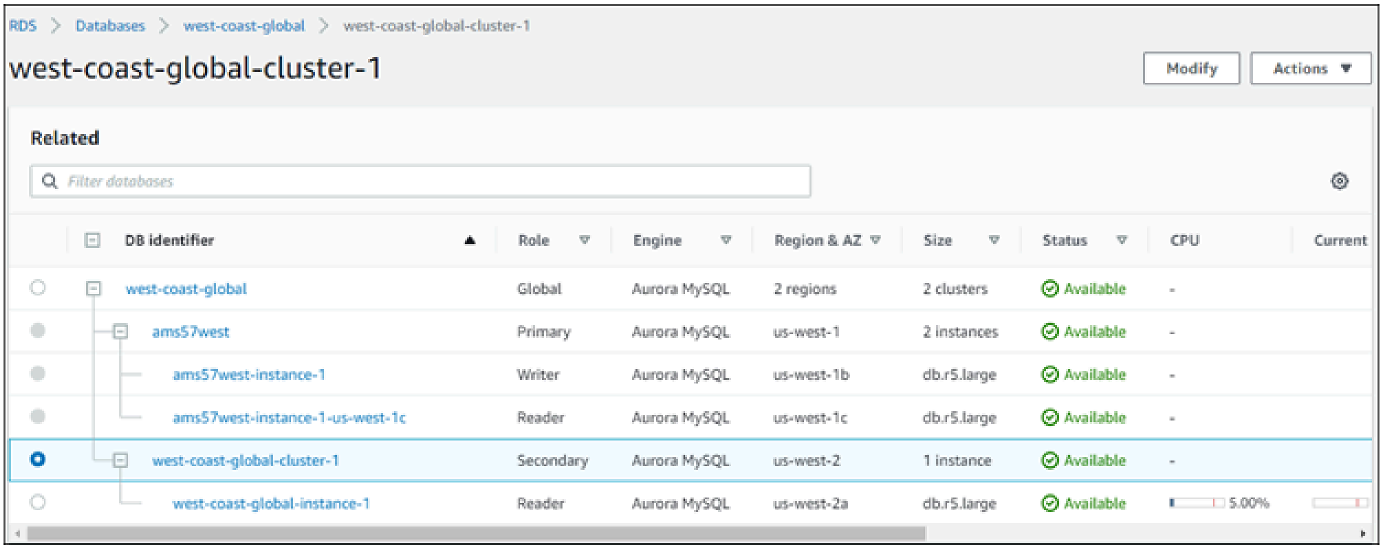
> ⚠ **Warning**
>
> With Aurora PostgreSQL, to create a headless cluster in a secondary AWS Region, use the AWS CLI or RDS API to add the secondary AWS Region. Skip the step to create the reader DB instance for the secondary cluster. Currently, creating a headless cluster isn't supported in the RDS Console. For the CLI and API procedures to use, see Adding an AWS Region to an Amazon Aurora global database.
> If your global database is using an engine version lower than 13.4, 12.8, or 11.13, creating a reader DB instance in a secondary Region and subsequently deleting it could lead to an Aurora PostgreSQL vacuum issue on the primary Region's writer DB instance. If you encounter this issue, restart the primary Region's writer DB instance after you delete the secondary Region's reader DB instance.

To add a headless secondary Aurora DB cluster to your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane of the AWS Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is `Available`.
4. For **Actions**, choose **Add region**.
5. On the **Add a region** page, choose the secondary AWS Region.

   You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.
6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance.

   For an Aurora MySQL–based Aurora global database, disregard the **Enable read replica write forwarding** option. This option has no function after you delete the reader instance.
7. Choose **Add region**. After you finish adding the Region to your Aurora global database, you can see it in the list of Databases in the AWS Management Console as shown in the screenshot.



RDS > Databases > west-coast-global > west-coast-global-cluster-1

west-coast-global-cluster-1

Related

	DB identifier	Role	Engine	Region & AZ	Size	Status	CPU	Current
○	west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	✓ Available	-

●	west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	1 instance	✓ Available	-	
○	west-coast-global-instance-1	Reader	Aurora MySQL	us-west-2a	db.r5.large	✓ Available	5.00%	

8. Check the status of the secondary Aurora DB cluster and its reader instance before continuing, by using the AWS Management Console or the AWS CLI. For example:

```
$ aws rds describe-db-clusters --db-cluster-identifier secondary-cluster-id --query
 '*[].[Status]' --output text
```

It can take several minutes for the status of a newly added secondary Aurora DB cluster to change from `creating` to `available`. When the Aurora DB cluster is available, you can delete the reader instance.

9. Select the reader instance in the secondary Aurora DB cluster, and then choose **Delete**.

You can use this headless secondary Aurora DB cluster to manually recover your Amazon Aurora global database from an unplanned outage in the primary AWS Region if such an outage occurs.

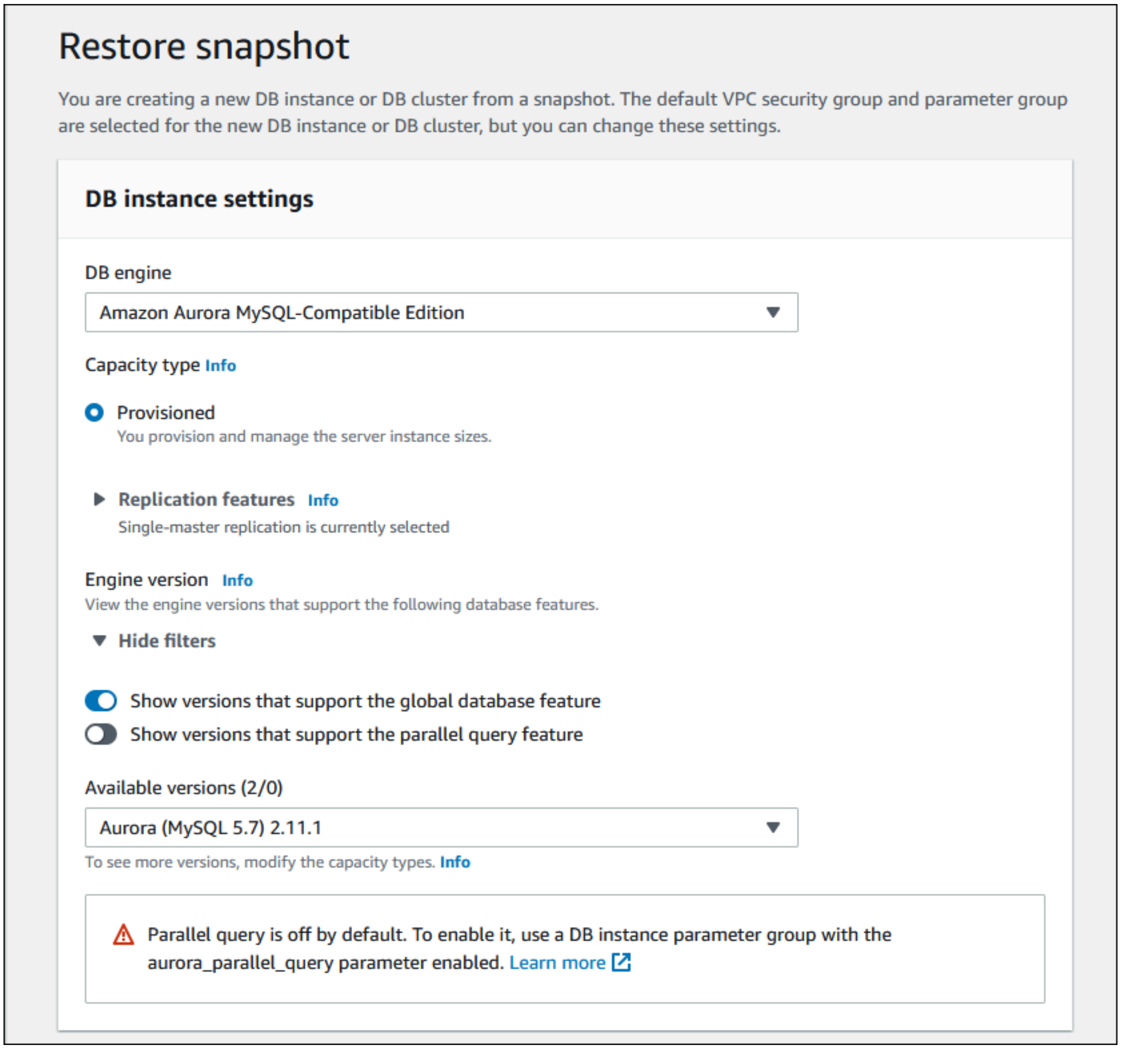
Using a snapshot for your Amazon Aurora global database

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora provisioned DB cluster at the same time. You then add another AWS Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.

The snapshot that you use can be from a `provisioned` or from a `serverless` Aurora DB cluster.

During the restore process, choose the same DB engine type as the snapshot. For example, suppose that you want to restore a snapshot that was made from an Aurora Serverless DB cluster running Aurora PostgreSQL. In this case, you create an Aurora PostgreSQL DB cluster using that same Aurora DB engine and version.

The restored DB cluster assumes the role of primary cluster for the Aurora global database when you add an AWS Region to it. All data contained in this primary cluster is replicated to any secondary clusters that you add to your Aurora global database.



Restore snapshot

You are creating a new DB instance or DB cluster from a snapshot. The default VPC security group and parameter group are selected for the new DB instance or DB cluster, but you can change these settings.

Managing an Amazon Aurora global database

You perform most management operations on the individual clusters that make up an Aurora global database. When you choose **Group related resources** on the **Databases** page in the console, you see the primary cluster and secondary clusters grouped under the associated global database. To find the AWS Regions where a global database's DB clusters are running, its Aurora DB engine and version, and its identifier, use its **Configuration** tab.

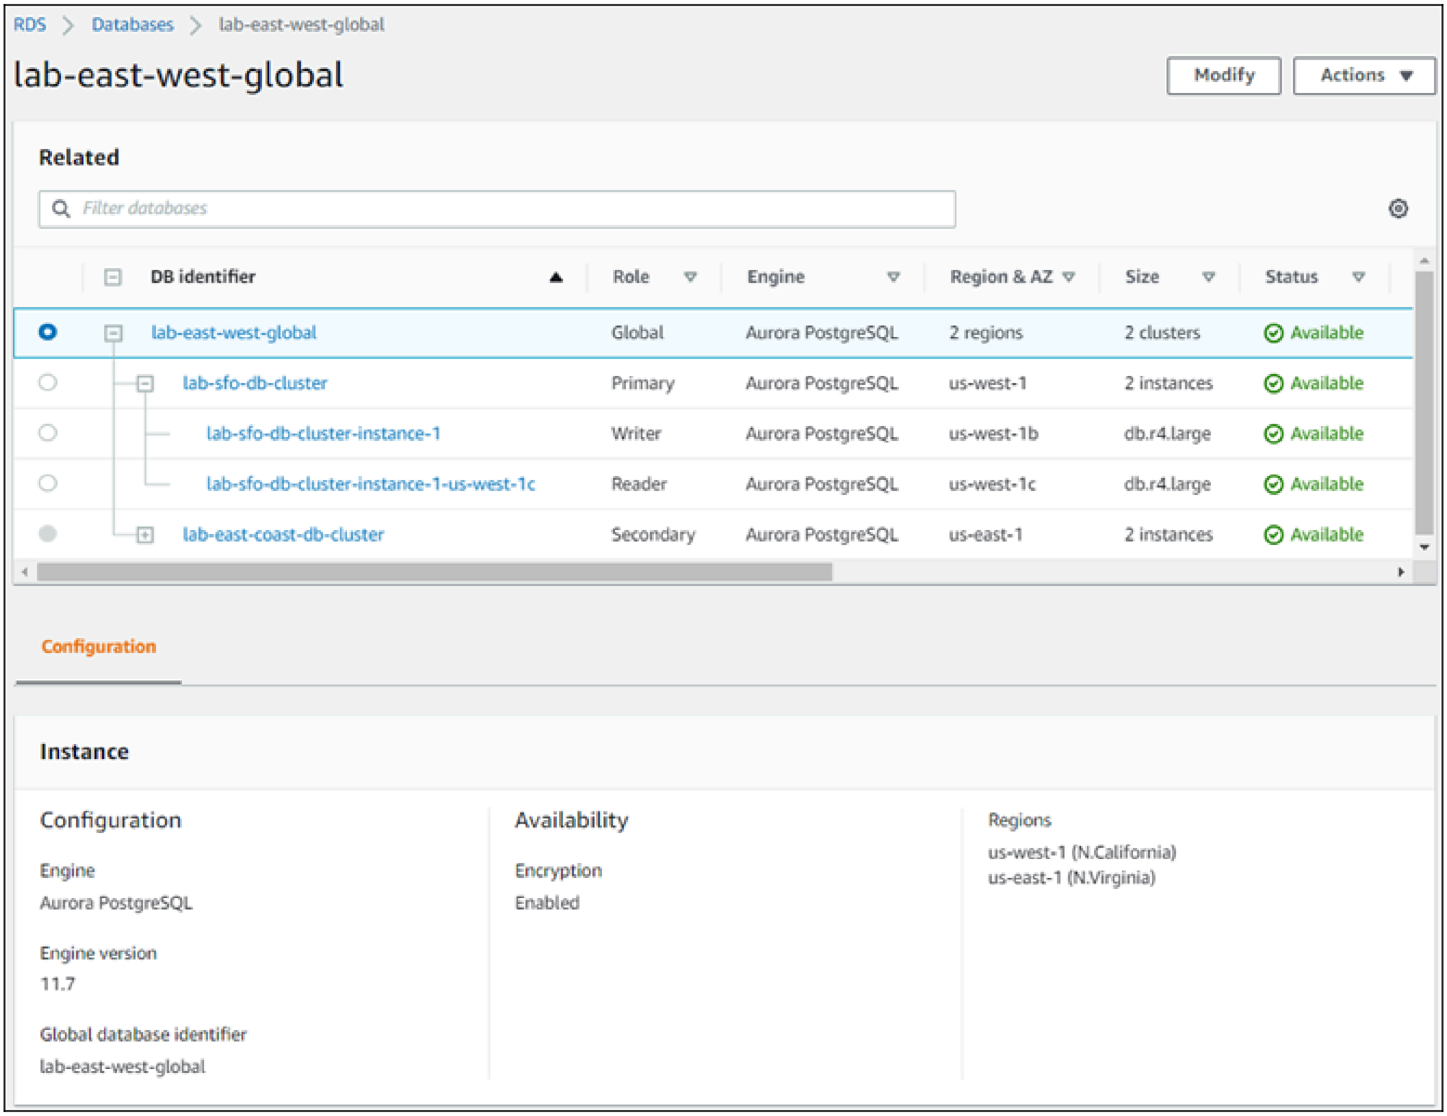
The cross-Region database failover processes are available to Aurora global databases only, not for a single Aurora DB cluster. To learn more, see Using switchover or failover in an Amazon Aurora global database.

To recover an Aurora global database from an unplanned outage in its primary Region, see Recovering an Amazon Aurora global database from an unplanned outage.

Topics

Modifying an Amazon Aurora global database

The **Databases** page in the AWS Management Console lists all your Aurora global databases, showing the primary cluster and secondary clusters for each one. The Aurora global database has its own configuration settings. Specifically, it has AWS Regions associated with its primary and secondary clusters, as shown in the screenshot following.



lab-east-west-global

Related

	DB identifier	Role	Engine	Region & AZ	Size	Status

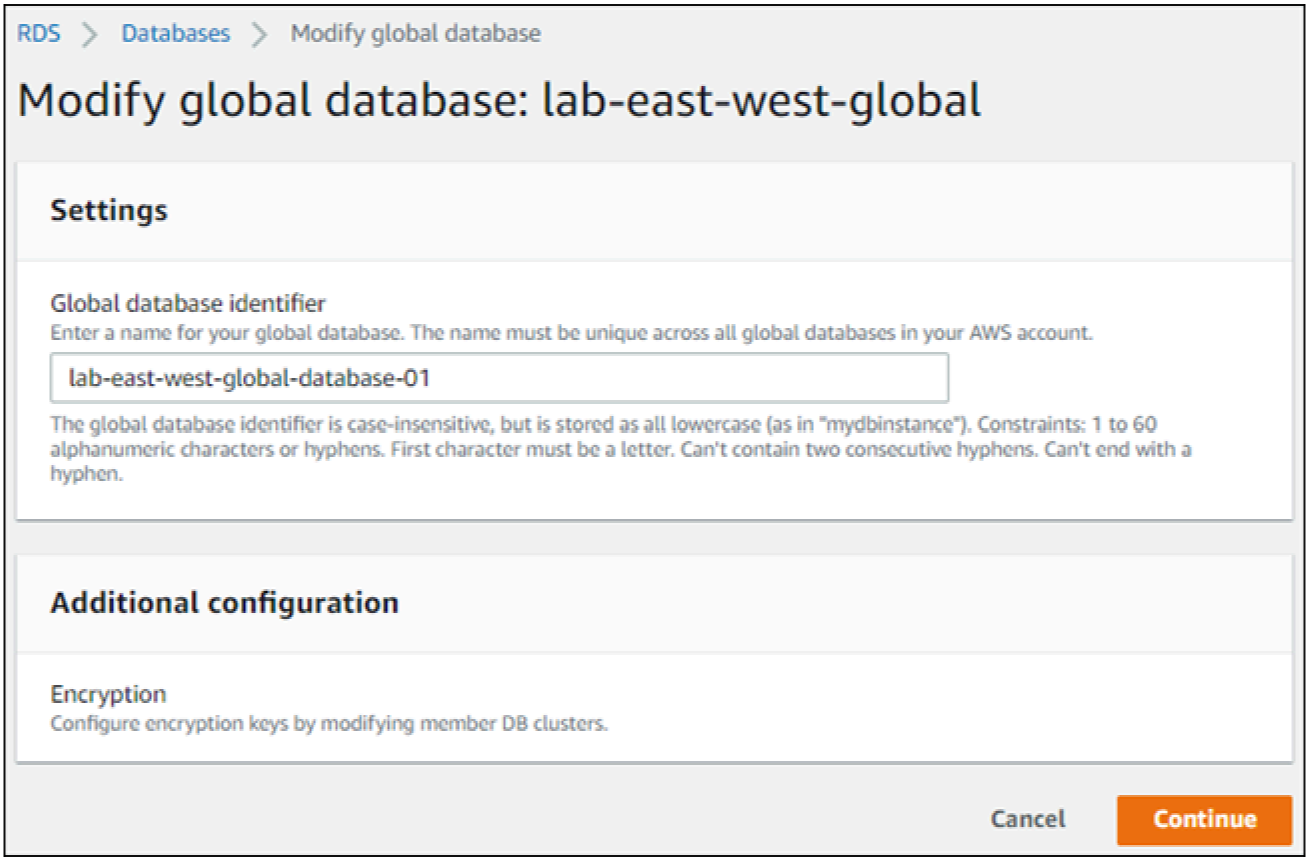
When you make changes to the Aurora global database, you have a chance to cancel changes, as shown in the following screenshot.



Modify global database: lab-east-west-global

Settings

Global database identifier

Enter a name for your global database. The name must be unique across all global databases in your AWS account.

lab-east-west-global-database-01

The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Additional configuration

Encryption

Configure encryption keys by modifying member DB clusters.

When you choose **Continue**, you confirm the changes.

Modifying parameters for an Aurora global database

You can configure the Aurora DB cluster parameter groups independently for each Aurora cluster within the Aurora global database. Most parameters work the same as for other kinds of Aurora clusters. We recommend that you keep settings consistent among all the clusters in a global database. Doing this helps to avoid unexpected behavior changes if you promote a secondary cluster to be the primary.

For example, use the same settings for time zones and character sets to avoid inconsistent behavior if a different cluster takes over as the primary cluster.

The `aurora_enable_repl_bin_log_filtering` and `aurora_enable_replica_log_compression` configuration settings have no effect.

Removing a cluster from an Amazon Aurora global database

You can remove Aurora DB clusters from your Aurora global database for several different reasons. For example, you might want to remove an Aurora DB cluster from an Aurora global database if the primary cluster becomes degraded or isolated. It then becomes a standalone provisioned Aurora DB cluster that could be used to create a new Aurora global database. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage.

You also might want to remove Aurora DB clusters because you want to delete an Aurora global database that you no longer need. You can't delete the Aurora global database until after you remove (detach) all associated Aurora DB clusters, leaving the primary for last. For more information, see Deleting an Amazon Aurora global database.

When an Aurora DB cluster is detached from the Aurora global database, it's no longer synchronized with the primary. It becomes a standalone provisioned Aurora DB cluster with full read/write capabilities.

You can remove Aurora DB clusters from your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

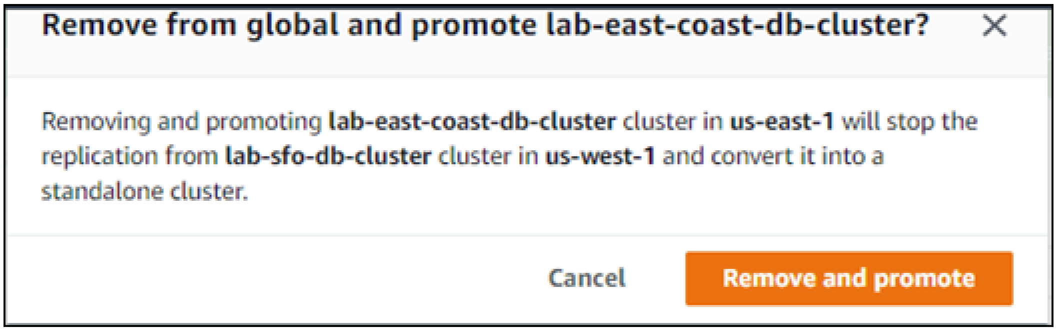
Console

To remove an Aurora cluster from an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the cluster on the **Databases** page.
3. For **Actions**, choose **Remove from Global**.

	DB identifier ▲	Role	Engine			Status
○	demo-ams5610a-global-database	Global	Aurora MySQL		ters	✓ Available
○	lab-ams5610a-global-database	Global	Aurora MySQL		ter	✓ Available
○	lab-east-west-global-database-01	Global	Aurora Postgr		ters	✓ Available
○	lab-sfo-db-cluster	Primary	Aurora Postgr		ances	✓ Available
○	lab-sfo-db-cluster-instance-1	Writer	Aurora Postgr		large	✓ Available
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	✓ Available
●	lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	✓ Available
○	lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large	✓ Available
○	lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	✓ Available

You see a prompt to confirm that you want to detach the secondary from the Aurora global database.

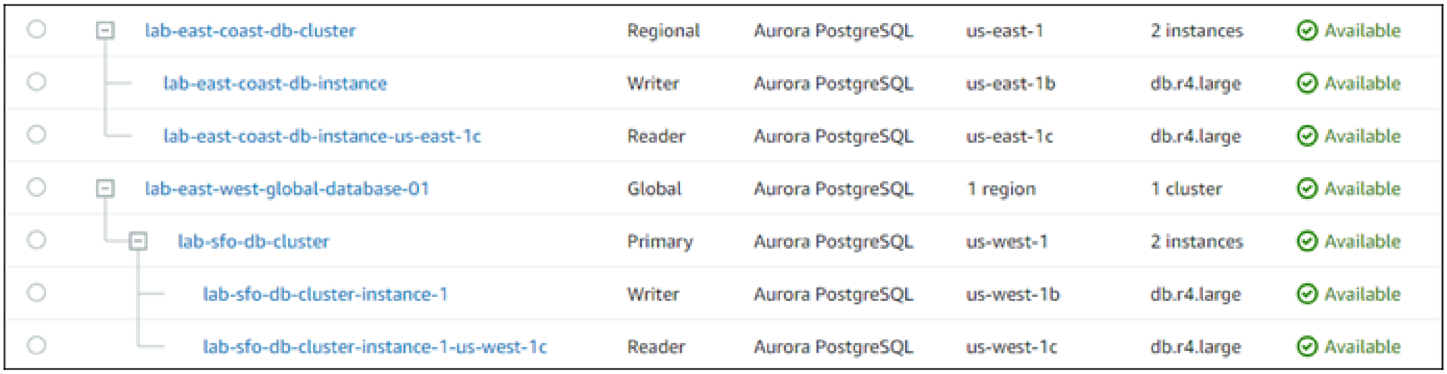


Remove from global and promote lab-east-coast-db-cluster?

Removing and promoting **lab-east-coast-db-cluster** cluster in **us-east-1** will stop the replication from **lab-sfo-db-cluster** cluster in **us-west-1** and convert it into a standalone cluster.

4. Choose **Remove and promote** to remove the cluster from the global database.

The Aurora DB cluster is no longer serving as a secondary in the Aurora global database, and is no longer synchronized with the primary DB cluster. It is a standalone Aurora DB cluster with full read/write capability.



○	⊟ lab-east-coast-db-cluster	Regional	Aurora PostgreSQL	us-east-1	2 instances	✓ Available
○	lab-east-coast-db-instance	Writer	Aurora PostgreSQL	us-east-1b	db.r4.large	✓ Available
○	lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	✓ Available
○	⊟ lab-east-west-global-database-01	Global	Aurora PostgreSQL	1 region	1 cluster	✓ Available
○	⊟ lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	✓ Available
○	lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	✓ Available
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	✓ Available

After you remove or delete all secondary clusters, then you can remove the primary cluster the same way. You can't detach (remove) the primary Aurora DB cluster from an Aurora global database until after you remove all secondary clusters.

The Aurora global database might remain in the **Databases** list, with zero Regions and AZs. You can delete if you no longer want to use this Aurora global database. For more information, see Deleting an Amazon Aurora global database.

AWS CLI

To remove an Aurora cluster from an Aurora global database, run the remove-from-global-cluster CLI command with the following parameters:

- `--global-cluster-identifier` – The name (identifier) of your Aurora global database.
- `--db-cluster-identifier` – The name of each Aurora DB cluster to remove from the Aurora global database. Remove all secondary Aurora DB clusters before removing the primary.

The following examples first remove a secondary cluster and then the primary cluster from an Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
  remove-from-global-cluster \
    --db-cluster-identifier secondary_cluster_ARN \
    --global-cluster-identifier global_database_id

aws rds --region primary_region \
  remove-from-global-cluster \
    --db-cluster-identifier primary_cluster_ARN \
    --global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier` *`secondary_cluster_ARN`* command for each secondary AWS Region in your Aurora global database.

For Windows:

```
aws rds --region secondary_region ^
  remove-from-global-cluster ^
    --db-cluster-identifier secondary_cluster_ARN ^
    --global-cluster-identifier global_database_id

aws rds --region primary_region ^
  remove-from-global-cluster ^
    --db-cluster-identifier primary_cluster_ARN ^
    --global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier` *`secondary_cluster_ARN`* command for each secondary AWS Region in your Aurora global database.

RDS API

To remove an Aurora cluster from an Aurora global database with the RDS API, run the RemoveFromGlobalCluster action.

Deleting an Amazon Aurora global database

Because an Aurora global database typically holds business-critical data, you can't delete the global database and its associated clusters in a single step. To delete an Aurora global database, do the following:

- Remove all secondary DB clusters from the Aurora global database. Each cluster becomes a standalone Aurora DB cluster. To learn how, see Removing a cluster from an Amazon Aurora global database.
- From each standalone Aurora DB cluster, delete all Aurora Replicas.
- Remove the primary DB cluster from the Aurora global database. This becomes a standalone Aurora DB cluster.
- From the Aurora primary DB cluster, first delete all Aurora Replicas, then delete the writer DB instance.

Deleting the writer instance from the newly standalone Aurora DB cluster also typically removes the Aurora DB cluster and the Aurora global database.

For more general information, see Deleting a DB instance from an Aurora DB cluster.

To delete an Aurora global database, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** and find the Aurora global database you want to delete in the listing.
3. Confirm that all clusters are removed from the Aurora global database. The Aurora global database should show 0 Regions and AZs and a size of 0 clusters.

   If the Aurora global database contains any Aurora DB clusters, you can't delete it. If necessary, detach the primary and secondary Aurora DB clusters from the Aurora global database. For more information, see Removing a cluster from an Amazon Aurora global database.
4. Choose your Aurora global database in the list, and then choose **Delete** from the **Actions** menu.

	DB identifier	Role	Engine	Region & AZ	Size	St
●	ams5610a-global-db-cluster-1	Global	Aurora MySQL	0 regions	0 clusters	✓
○	ams5610a-global-db-cluster-1-cluster-1	Regional	Aurora MySQL	us-east-1	0 instances	✓
○	demo-apg1012-global-database-n-hemisphere	Global	Aurora PostgreSQL	2 regions	2 clusters	✓

AWS CLI

To delete an Aurora global database, run the delete-global-cluster CLI command with the name of the AWS Region and the Aurora global database identifier, as shown in the following example.

For Linux, macOS, or Unix:

```
aws rds --region primary_region delete-global-cluster \
   --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds --region primary_region delete-global-cluster ^
   --global-cluster-identifier global_database_id
```

RDS API

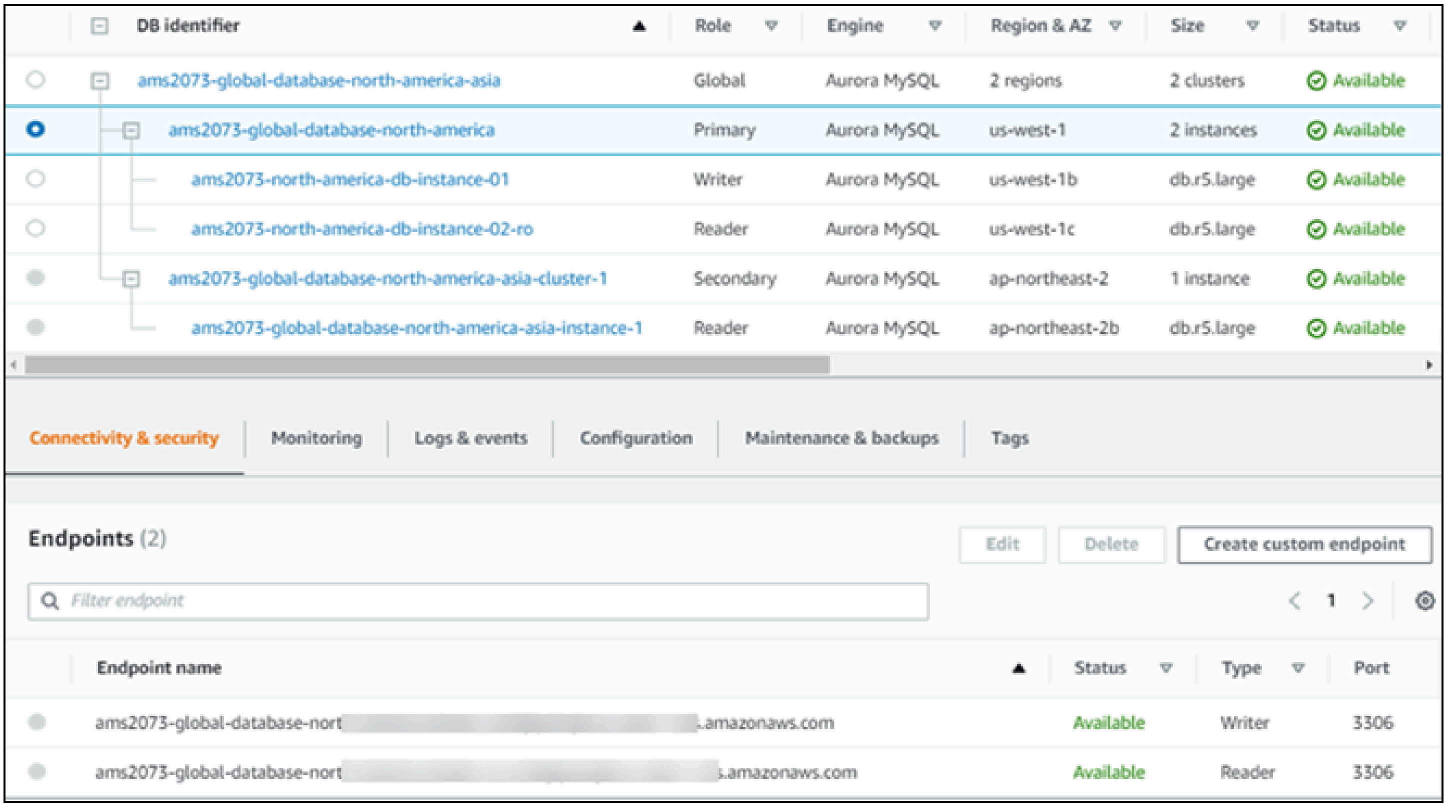
To delete a cluster that is part of an Aurora global database, run the DeleteGlobalCluster API operation.

Connecting to an Amazon Aurora global database

How you connect to an Aurora global database depends on whether you need to write to the database or read from the database:

- For read-only requests or queries, you connect to the reader endpoint for the Aurora cluster in your AWS Region.
- To run data manipulation language (DML) or data definition language (DDL) statements, you connect to the cluster endpoint for the primary cluster. This endpoint might be in a different AWS Region than your application.

When you view an Aurora global database in the console, you can see all the general-purpose endpoints associated with all of its clusters. The following screenshot shows an example. There is a single cluster endpoint associated with the primary cluster that you use for write operations. The primary cluster and each secondary cluster has a reader endpoint that you use for read-only queries. To minimize latency, choose whichever reader endpoint is in your AWS Region or the AWS Region closest to you. The following shows an Aurora MySQL example.



DB identifier	Role	Engine	Region & AZ	Size	Status
ams2073-global-database-north-america-asia	Global	Aurora MySQL	2 regions	2 clusters	Available
ams2073-global-database-north-america	Primary	Aurora MySQL	us-west-1	2 instances	Available
ams2073-north-america-db-instance-01	Writer	Aurora MySQL	us-west-1b	db.r5.large	Available
ams2073-north-america-db-instance-02-ro	Reader	Aurora MySQL	us-west-1c	db.r5.large	Available
ams2073-global-database-north-america-asia-cluster-1	Secondary	Aurora MySQL	ap-northeast-2	1 instance	Available
ams2073-global-database-north-america-asia-instance-1	Reader	Aurora MySQL	ap-northeast-2b	db.r5.large	Available

Endpoint name	Status	Type	Port
ams2073-global-database-nort[redacted].amazonaws.com	Available	Writer	3306
ams2073-global-database-nort[redacted].amazonaws.com	Available	Reader	3306

Using write forwarding in an Amazon Aurora global database

You can reduce the number of endpoints that you need to manage for applications running on your Aurora global database, by using *write forwarding*. With write forwarding enabled, secondary clusters in an Aurora global database forward SQL statements that perform write operations to the primary cluster. The primary cluster updates the source and then propagates resulting changes back to all secondary AWS Regions.

The write forwarding configuration saves you from implementing your own mechanism to send write operations from a secondary AWS Region to the primary Region. Aurora handles the cross-Region networking setup. Aurora also transmits all necessary session and transactional context for each statement. The data is always changed first on the primary cluster and then replicated to the secondary clusters in the Aurora global database. This way, the primary cluster is the source of truth and always has an up-to-date copy of all your data.

Using write forwarding in an Aurora MySQL global database

Topics

Region and version availability of write forwarding in Aurora MySQL

Write forwarding is supported with Aurora MySQL 2.08.1 and higher versions, in every Region where Aurora MySQL-based global databases are available.

For information on version and Region availability of Aurora MySQL global databases, see Aurora global databases with Aurora MySQL.

Enabling write forwarding in Aurora MySQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database.

To enable write forwarding using the AWS Management Console, select the **Turn on global write forwarding** check box under **Read replica write forwarding** when you add a Region for a global database. For an existing secondary cluster, modify the cluster to **Turn on global write forwarding**. To turn off write forwarding, clear the **Turn on global write forwarding** check box when adding the Region or modifying the secondary cluster.

To enable write forwarding using the AWS CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the `create-db-cluster` command. It also works when you modify an existing secondary cluster using the modify-db-cluster command. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by using the --no-enable-global-write-forwarding option with these same CLI commands.

To enable write forwarding using the Amazon RDS API, set the EnableGlobalWriteForwarding parameter to true. This parameter works when you create a new secondary cluster using the CreateDBCluster operation. It also works when you modify an existing secondary cluster using the ModifyDBCluster operation. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by setting the EnableGlobalWriteForwarding parameter to false.

> **Note**
>
> For a database session to use write forwarding, specify a setting for the aurora_replica_read_consistency configuration parameter. Do this in every session that uses the write forwarding feature. For information about this parameter, see Isolation and consistency for write forwarding in Aurora MySQL.
> The RDS Proxy feature doesn't support the SESSION value for the aurora_replica_read_consistency variable. Setting this value can cause unexpected behavior.

The following CLI examples show how you can set up an Aurora global database with write forwarding enabled or disabled. The highlighted items represent the commands and options that are important to specify and keep consistent when setting up the infrastructure for an Aurora global database.

The following example creates an Aurora global database, a primary cluster, and a secondary cluster with write forwarding enabled. Substitute your own choices for the user name, password, and primary and secondary AWS Regions.

```
# Create overall global database.
aws rds create-global-cluster --global-cluster-identifier write-forwarding-test \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

# Create primary cluster, in the same AWS Region as the global database.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-1 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --master-username user_name --master-user-password password \
  --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
  --db-instance-identifier write-forwarding-test-cluster-1-instance-1 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
  --db-instance-identifier write-forwarding-test-cluster-1-instance-2 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

# Create secondary cluster, in a different AWS Region than the global database,
# with write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-2 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-2 \
  --enable-global-write-forwarding

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-2

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-2
```

The following example continues from the previous one. It creates a secondary cluster without write forwarding enabled, then enables write forwarding. After this example finishes, all secondary clusters in the global database have write forwarding enabled.

```
# Create secondary cluster, in a different AWS Region than the global database,
# without write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-2 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-west-1

aws rds modify-db-cluster --db-cluster-identifier write-forwarding-test-cluster-2 \
  --region us-east-2 \
  --enable-global-write-forwarding
```

Checking if a secondary cluster has write forwarding enabled in Aurora MySQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute `"GlobalWriteForwardingStatus": "enabled"`.

In the AWS Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Global read replica write forwarding**.

To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value `"enabled"` or `"disabled"` to indicate if write forwarding is turned on or off. A value of `null` indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be `"enabling"` or `"disabling"` if write forwarding is in the process of being turned on or off.

Example

```
aws rds describe-db-clusters \
--query '*[].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatu
```

```
[
    {
        "GlobalWriteForwardingStatus": "enabled",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
    },
    {
        "GlobalWriteForwardingStatus": "disabled",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
    },
    {
        "GlobalWriteForwardingStatus": null,
        "DBClusterIdentifier": "non-global-cluster"
    }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

Example

```
aws rds describe-db-clusters --query 'DBClusters[].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatu
 | [?GlobalWriteForwardingStatus == `enabled`]'
[
    {
        "GlobalWriteForwardingStatus": "enabled",
        "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-
cnpexample.us-west-2.rds.amazonaws.com",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
    }
]
```

Application and SQL compatibility with write forwarding in Aurora MySQL

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.

- `SELECT ... LOCK IN SHARE MODE` and `SELECT FOR UPDATE` statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the `EnableGlobalWriteForwarding` setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on secondary clusters with write forwarding enabled at the cluster level. This approach works if write forwarding isn't turned on within the session by the `aurora_replica_read_consistency` configuration parameter. Trying to use a statement when it's not allowed because of write forwarding causes an error message with the following format.

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation with write
 forwarding'.
```

Data definition language (DDL)

Connect to the primary cluster to run DDL statements. You can't run them from reader DB instances.

Updating a permanent table using data from a temporary table

You can use temporary tables on secondary clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an `INSERT ... SELECT` statement that takes the data from a temporary table. The temporary table exists on the secondary cluster and isn't available when the statement runs on the primary cluster.

XA transactions

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is empty. Before turning on write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

LOAD statements for permanent tables

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
        LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

You can load data into a temporary table on a secondary cluster. However, make sure that you run any LOAD statements that refer to permanent tables only on the primary cluster.

Plugin statements

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

SAVEPOINT statements

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the aurora_replica_read_consistency setting is blank. Check if your code uses these statements before turning on write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```

Isolation and consistency for write forwarding in Aurora MySQL

In sessions that use write forwarding, you can only use the REPEATABLE READ isolation level. Although you can also use the READ COMMITTED isolation level with read-only clusters in secondary AWS Regions, that isolation level doesn't work with write forwarding. For information about the `REPEATABLE READ` and `READ COMMITTED` isolation levels, see [Aurora MySQL isolation levels](#).

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose a value for the session-level parameter `aurora_replica_read_consistency`.

> ⚠ **Important**
>
> Always set the `aurora_replica_read_consistency` parameter for any session for which you want to forward writes. If you don't, Aurora doesn't enable write forwarding for that session. This parameter has an empty value by default, so choose a specific value when you use this parameter. The `aurora_replica_read_consistency` parameter has an effect only on secondary clusters that have write forwarding enabled.
> For Aurora MySQL version 2 and version 3 lower than 3.04, use `aurora_replica_read_consistency` as a session variable. For Aurora MySQL version 3.04 and higher, you can use `aurora_replica_read_consistency` as either a session variable or as a DB cluster parameter.

For the `aurora_replica_read_consistency` parameter, you can specify the values `EVENTUAL`, `SESSION`, and `GLOBAL`.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With the read consistency set to `EVENTUAL`, queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available.

Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

With the read consistency set to SESSION, all queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

With the read consistency set to GLOBAL, a session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

For more information about all the parameters involved with write forwarding, see Configuration parameters for write forwarding in Aurora MySQL.

Examples of using write forwarding

These examples use aurora_replica_read_consistency as a session variable. For Aurora MySQL version 3.04 and higher, you can use aurora_replica_read_consistency as either a session variable or as a DB cluster parameter.

In the following example, the primary cluster is in the US East (N. Virginia) Region. The secondary cluster is in the US East (Ohio) Region. The example shows the effects of running INSERT statements followed by SELECT statements. Depending on the value of the aurora_replica_read_consistency setting, the results might differ depending on the timing of the statements. To achieve higher consistency, you might wait briefly before issuing the SELECT statement. Or Aurora can automatically wait until the results finish replicating before proceeding with SELECT.

In this example, there is a read consistency setting of eventual. Running an INSERT statement immediately followed by a SELECT statement still returns the value of COUNT(*). This value reflects the number of rows before the new row is inserted. Running the SELECT again a short time later returns the updated row count. The SELECT statements don't wait.

```
mysql> set aurora_replica_read_consistency = 'eventual';
mysql> select count(*) from t1;
```

```
+----------+
| count(*) |
+----------+
|        5 |
+----------+
1 row in set (0.00 sec)
mysql> insert into t1 values (6); select count(*) from t1;
+----------+
| count(*) |
+----------+
|        5 |
+----------+
1 row in set (0.00 sec)
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        6 |
+----------+
1 row in set (0.00 sec)
```

With a read consistency setting of `session`, a `SELECT` statement immediately after an `INSERT` waits until the changes from the `INSERT` statement are visible. Subsequent `SELECT` statements don't wait.

```
mysql> set aurora_replica_read_consistency = 'session';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        6 |
+----------+
1 row in set (0.01 sec)
mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+----------+
| count(*) |
+----------+
|        7 |
+----------+
1 row in set (0.37 sec)
+----------+
| count(*) |
+----------+
|        7 |
+----------+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `session`, introducing a brief wait after performing an `INSERT` statement makes the updated row count available by the time the next `SELECT` statement runs.

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+----------+
| sleep(2) |
+----------+
|        0 |
+----------+
1 row in set (2.01 sec)
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.00 sec)
```

With a read consistency setting of `global`, each `SELECT` statement waits to ensure that all data changes as of the start time of the statement are visible before performing the query. The amount of waiting for each `SELECT` statement varies, depending on the amount of replication lag between the primary and secondary clusters.

```
mysql> set aurora_replica_read_consistency = 'global';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.75 sec)
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.37 sec)
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.66 sec)
```

Running multipart statements with write forwarding in Aurora MySQL

A DML statement might consist of multiple parts, such as a `INSERT ... SELECT` statement or a `DELETE ... WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Transactions with write forwarding in Aurora MySQL

Whether the transaction is forwarded to the primary cluster depends on the access mode of the transaction. You can specify the access mode for the transaction by using the `SET TRANSACTION` statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the Aurora MySQL session variable `tx_read_only`. You can only change this session value while you're connected to a secondary cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can increase it up to one day. A transaction that exceeds the idle timeout is canceled by the primary cluster. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the primary cluster or if you turn off the write forwarding configuration setting.

Configuration parameters for write forwarding in Aurora MySQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Name	Scope	Type	Default value	Valid values
`aurora_fwd_master_idle_timeout` (Aurora MySQL version 2)	Global	unsigned integer	60	1–86,400
`aurora_fwd_master_max_connections_pct` (Aurora MySQL version 2)	Global	unsigned long integer	10	0–90
`aurora_fwd_writer_idle_timeout` (Aurora MySQL version 3)	Global	unsigned integer	60	1–86,400
`aurora_fwd_writer_max_connections_pct` (Aurora MySQL version 3)	Global	unsigned long integer	10	0–90
`aurora_replica_read_consistency`	Session	Enum	'' (null)	`EVENTUAL`, `SESSION`, `GLOBAL`

To control incoming write requests from secondary clusters, use these settings on the primary cluster:

- `aurora_fwd_master_idle_timeout`, `aurora_fwd_writer_idle_timeout`: The number of seconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora cancels the session.
- `aurora_fwd_master_max_connections_pct`, `aurora_fwd_writer_max_connections_pct`: The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from readers. It's expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is 800 and `aurora_fwd_master_max_connections_pct` or `aurora_fwd_writer_max_connections_pct` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting.

This setting applies only on the primary cluster, when one or more secondary clusters have write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a secondary cluster. The default value is 10, representing 10% of the `max_connections` value. If you enable query forwarding on any of the secondary clusters, this setting must have a nonzero value for write operations from secondary clusters to succeed. If the value is zero, the write operations receive the error code `ER_CON_COUNT_ERROR` with the message `Not enough connections on writer to handle your request`.

The `aurora_replica_read_consistency` parameter is a session-level parameter that enables write forwarding. You use it in each session. You can specify `EVENTUAL`, `SESSION`, or `GLOBAL` for read consistency level. To learn more about consistency levels, see [Isolation and consistency for write forwarding in Aurora MySQL](). The following rules apply to this parameter:

- This is a session-level parameter. The default value is '' (empty).
- Write forwarding is available in a session only if `aurora_replica_read_consistency` is set to `EVENTUAL` or `SESSION` or `GLOBAL`. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- You can't set this variable (when empty) or unset (when already set) inside a multistatement transaction. However, you can change it from one valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) to another valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) during such a transaction.
- The variable can't be `SET` when write forwarding isn't enabled on the secondary cluster.
- Setting the session variable on a primary cluster doesn't have any effect. If you try to modify this variable on a primary cluster, you receive an error.

Amazon CloudWatch metrics for write forwarding in Aurora MySQL

The following Amazon CloudWatch metrics and Aurora MySQL status variables apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
`ForwardingMasterDMLLatency`	–	Milliseconds	Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request, or the time to replicate changes back to the secondary cluster. For Aurora MySQL version 2.
`ForwardingMasterDMLThroughput`	–	Count per second	Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 2.
`ForwardingMasterOpenSessions`	`Aurora_fwd_master_open_sessions`	Count	Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 2.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
–	Aurora_fwd_master_dml_stmt_count	Count	Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.
–	Aurora_fwd_master_dml_stmt_duration	Microseconds	Total duration of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.
–	Aurora_fwd_master_select_stmt_count	Count	Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.
–	Aurora_fwd_master_select_stmt_duration	Microseconds	Total duration of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
`ForwardingWriterDMLLatency`	–	Milliseconds	Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request, or the time to replicate changes back to the secondary cluster. For Aurora MySQL version 3.
`ForwardingWriterDMLThroughput`	–	Count per second	Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 3.
`ForwardingWriterOpenSessions`	`Aurora_fwd_writer_open_sessions`	Count	Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 3.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
–	`Aurora_fwd_writer_dml_stmt_count`	Count	Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 3.
–	`Aurora_fwd_writer_dml_stmt_duration`	Microseconds	Total duration of DML statements forwarded to this writer DB instance.
–	`Aurora_fwd_writer_select_stmt_count`	Count	Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 3.
–	`Aurora_fwd_writer_select_stmt_duration`	Microseconds	Total duration of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 3.

The following CloudWatch metrics and Aurora MySQL status variables apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
`ForwardingReplicaDMLLatency`	–	Milliseconds	Average response time of forwarded DMLs on the replica.
`ForwardingReplicaDMLThroughput`	–	Count per second	Number of forwarded DML statements processed each second.
`ForwardingReplicaOpenSessions`	`Aurora_fwd_replica_open_sessions`	Count	Number of sessions that are using write forwarding on a reader DB instance.
`ForwardingReplicaReadWaitLatency`	–	Milliseconds	Average wait time that a `SELECT` statement on a reader DB instance waits to catch up to the primary cluster. The degree to which the reader DB instance waits before processing a query depends on the `aurora_replica_read_consistency` setting.
`ForwardingReplicaReadWaitThroughput`	–	Count per second	Total number of `SELECT` statements processed each second in all sessions

CloudWatch metric	Aurora MySQL status variable	Unit	Description
			that are forwarding writes.
`ForwardingReplicaSelectLatency`	(–)	Milliseconds	Forwarded `SELECT` latency, average over all forwarded `SELECT` statements within the monitoring period.
`ForwardingReplicaSelectThroughput`	–	Count per second	Forwarded `SELECT` throughput per second average within the monitoring period.
–	`Aurora_fwd_replica_dml_stmt_count`	Count	Total number of DML statements forwarded from this reader DB instance.
–	`Aurora_fwd_replica_dml_stmt_duration`	Microseconds	Total duration of all DML statements forwarded from this reader DB instance.

CloudWatch metric	Aurora MySQL status variable	Unit	Description
–	`Aurora_fwd_replica_errors_session_limit`	Count	Number of sessions rejected by the primary cluster due to one of the following error conditions: • writer full • Too many forwarded statements in progress.
–	`Aurora_fwd_replica_read_wait_count`	Count	Total number of read-after-write waits on this reader DB instance.
–	`Aurora_fwd_replica_read_wait_duration`	Microseconds	Total duration of waits due to the read consistency setting on this reader DB instance.
–	`Aurora_fwd_replica_select_stmt_count`	Count	Total number of SELECT statements forwarded from this reader DB instance.
–	`Aurora_fwd_replica_select_stmt_duration`	Microseconds	Total duration of SELECT statements forwarded from this reader DB instance.

Using write forwarding in an Aurora PostgreSQL global database

Topics

Region and version availability of write forwarding in Aurora PostgreSQL

Write forwarding is supported with Aurora PostgreSQL version 15.4 and higher minor versions, and version 14.9 and higher minor versions. Write forwarding is available in every Region where Aurora PostgreSQL-based global databases are available.

For more information on version and Region availability of Aurora PostgreSQL global databases, see Aurora global databases with Aurora PostgreSQL.

Enabling write forwarding in Aurora PostgreSQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database. You can enable write forwarding for your secondary DB cluster while you're creating it or anytime after you create it. If needed, you can disable it later. Enabling or disabling write forwarding doesn't cause downtime or a reboot.

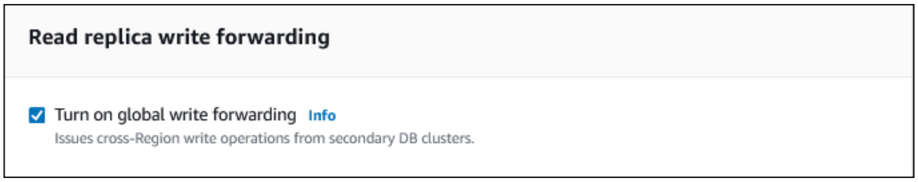
Console

In the console, you can enable or disable write forwarding when you create or modify a secondary DB cluster.

Enabling or disabling write forwarding when creating a secondary DB cluster

When you create a new secondary DB cluster, you enable write forwarding by selecting the **Turn on global write forwarding** check box under **Read replica write forwarding**. Or clear the check box to disable it. To create a secondary DB cluster, follow the instructions for your DB engine in Creating an Amazon Aurora DB cluster.

The following screenshot shows the **Read replica write forwarding** section with the **Turn on global write forwarding** check box selected.



Read replica write forwarding

☑ Turn on global write forwarding Info
Issues cross-Region write operations from secondary DB clusters.

Enabling or disabling write forwarding when modifying a secondary DB cluster

In the console, you can modify a secondary DB cluster to enable or disable write forwarding.

To enable or disable write forwarding for a secondary DB cluster by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. Choose the secondary DB cluster, and choose **Modify**.
4. In the **Read replica write forwarding** section, check or clear the **Turn on global write forwarding** check box.
5. Choose **Continue**.
6. For **Schedule modifications**, choose **Apply immediately**. If you choose **Apply during the next scheduled maintenance window**, Aurora ignores this setting and turns on write forwarding immediately.
7. Choose **Modify cluster**.

AWS CLI

To enable write forwarding by using the AWS CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the create-db-cluster command. It also works when you modify an existing secondary cluster using the modify-db-cluster command. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by using the `--no-enable-global-write-forwarding` option with these same CLI commands.

The following procedures describe how to enable or disable write forwarding for a secondary DB cluster in your global cluster by using the AWS CLI.

To enable or disable write forwarding for an existing secondary DB cluster

- Call the [modify-db-cluster](https://docs.aws.amazon.com/cli/latest/reference/rds/modify-db-cluster.html) AWS CLI command and supply the following values:

  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--enable-global-write-forwarding` to turn on or `--no-enable-global-write-forwarding` to turn off.

  The following example enables write forwarding for DB cluster `sample-secondary-db-cluster`.

  For Linux, macOS, or Unix:

  ```
  aws rds modify-db-cluster \
      --db-cluster-identifier sample-secondary-db-cluster \
      --enable-global-write-forwarding
  ```

  For Windows:

  ```
  aws rds modify-db-cluster ^
      --db-cluster-identifier sample-secondary-db-cluster ^
      --enable-global-write-forwarding
  ```

RDS API

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the CreateDBCluster operation. It also works when you modify an existing secondary cluster using the ModifyDBCluster operation. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by setting the `EnableGlobalWriteForwarding` parameter to `false`.

Checking if a secondary cluster has write forwarding enabled in Aurora PostgreSQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute `"GlobalWriteForwardingStatus": "enabled"`.

In the AWS Management Console, you see `Read replica write forwarding` on the **Configuration** tab of the details page for the cluster. To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value `"enabled"` or `"disabled"` to indicate if write forwarding is turned on or off. A value of `null` indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be `"enabling"` or `"disabling"` if write forwarding is in the process of being turned on or off.

Example

```
aws rds describe-db-clusters --query '*[].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatu
[
    {
        "GlobalWriteForwardingStatus": "enabled",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
    },
    {
        "GlobalWriteForwardingStatus": "disabled",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
    },
    {
        "GlobalWriteForwardingStatus": null,
        "DBClusterIdentifier": "non-global-cluster"
    }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

Example

```
aws rds describe-db-clusters --query 'DBClusters[].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatu
 | [?GlobalWriteForwardingStatus == `enabled`]'
[
    {
        "GlobalWriteForwardingStatus": "enabled",
        "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-
cnpexample.us-west-2.rds.amazonaws.com",
        "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
    }
]
```

Application and SQL compatibility with write forwarding in Aurora PostgreSQL

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. In addition, user defined functions and user defined procedures aren't supported. Thus, the `EnableGlobalWriteForwarding` setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`
- `SELECT FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE }` statements
- `PREPARE` and `EXECUTE` statements
- `EXPLAIN` statements with the statements in this list

The following kinds of SQL statements aren't supported with write forwarding:

- Data definition language (DDL) statements
- `ANALYZE`
- `CLUSTER`
- `COPY`
- Cursors – Cursors aren't supported, so make sure to close them before using write forwarding.
- `GRANT|REVOKE|REASSIGN OWNED|SECURITY LABEL`
- `LOCK`

- SAVEPOINT statements
- SELECT INTO
- SET CONSTRAINTS
- TRUNCATE
- VACUUM

Isolation and consistency for write forwarding in Aurora PostgreSQL

In sessions that use write forwarding, you can use the REPEATABLE READ and READ COMMITTED isolation levels. However, the SERIALIZABLE isolation level isn't supported.

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose the appropriate value for the session-level parameter apg_write_forward.consistency_mode. The apg_write_forward.consistency_mode parameter has an effect only on secondary clusters that have write forwarding enabled.

Note

For the apg_write_forward.consistency_mode parameter, you can specify the value SESSION, EVENTUAL, GLOBAL, or OFF. By default, the value is set to SESSION. Setting the value to OFF disables write forwarding in the session.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With each available consistency mode setting, the effect is as follows:

- SESSION – All queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

- `EVENTUAL` – Queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.
- `GLOBAL` – A session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.
- `OFF` – Write forwarding is disabled in the session.

For more information about all the parameters involved with write forwarding, see Configuration parameters for write forwarding in Aurora PostgreSQL.

Running multipart statements with write forwarding in Aurora PostgreSQL

A DML statement might consist of multiple parts, such as a `INSERT ... SELECT` statement or a `DELETE ... WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Configuration parameters for write forwarding in Aurora PostgreSQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Name	Scope	Type	Default value	Valid values
`apg_write_forward.connect_timeout`	Session	seconds	30	0–2147483647
`apg_write_forward.consistency_mode`	Session	enum	Session	`SESSION`, `EVENTUAL`, `GLOBAL`, `OFF`
`apg_write_forward.idle_in_transaction_session_timeout`	Session	milliseconds	86400000	0–2147483647
`apg_write_forward.idle_session_timeout`	Session	milliseconds	300000	0–2147483647
`apg_write_forward.max_forwarding_connections_percent`	Global	int	25	1–100

The `apg_write_forward.max_forwarding_connections_percent` parameter is the upper limit on database connection slots that can be used to handle queries forwarded from readers. It is expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is `800` and `apg_write_forward.max_forwarding_connections_percent` is `10`, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting. This setting applies only on the primary cluster when at least one secondary clusters has write forwarding enabled.

Use the following settings on the secondary cluster:

- `apg_write_forward.consistency_mode` – A session-level parameter that controls the degree of read consistency on the secondary cluster. Valid values are `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF`. By default, the value is set to `SESSION`. Setting the value to `OFF` disables write forwarding in the session. To learn more about consistency levels, see Isolation and consistency for write forwarding in Aurora PostgreSQL. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.

- `apg_write_forward.connect_timeout` – The maximum number of seconds the secondary cluster waits when establishing a connection to the primary cluster before giving up. A value of `0` means to wait indefinitely.
- `apg_write_forward.idle_in_transaction_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster that has an open transaction before closing it. If the session remains idle in transaction beyond this period, Aurora terminates the session. A value of `0` disables the timeout.
- `apg_write_forward.idle_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora terminates the session. A value of `0` disables the timeout.

Amazon CloudWatch metrics for write forwarding in Aurora PostgreSQL

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

CloudWatch Metric	Units and description
`AuroraForwardingWriterDMLThroughput`	Count (per second). Number of forwarded DML statements processed each second by this writer DB instance.
`AuroraForwardingWriterOpenSessions`	Count. Number of open sessions on this writer DB instance processing forwarded queries.
`AuroraForwardingWriterTotalSessions`	Count. Total number of forwarded sessions on this writer DB instance.

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch Metric	Unit and description
`AuroraForwardingReplicaCommitThroughput`	Count (per second). Number of commits in sessions forwarded by this replica each second.
`AuroraForwardingReplicaDMLLatency`	Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.
`AuroraForwardingReplicaDMLThroughput`	Count (per second). Number of forwarded DML statements processed on this replica each second.
`AuroraForwardingReplicaErrorSessionsLimit`	Count. Number of sessions rejected by the primary cluster because the limit for max connections or max write forward connections was reached.
`AuroraForwardingReplicaOpenSessions`	Count. The number of sessions that are using write forwarding on a replica instance.
`AuroraForwardingReplicaReadWaitLatency`	Milliseconds. Average wait time in milliseconds that the replica waits to be consistent with the LSN of the primary cluster. The degree to which the reader DB instance waits depends on the `apg_write_forward.consistency_mode` setting. For information about this setting, see the section called "Configuration parameters for write forwarding in Aurora PostgreSQL".

Wait events for write forwarding in Aurora PostgreSQL

Amazon Aurora generates the following wait events when you use write forwarding with Aurora PostgreSQL.

Topics

- IPC:AuroraWriteForwardConnect
- IPC:AuroraWriteForwardConsistencyPoint
- IPC:AuroraWriteForwardExecute
- IPC:AuroraWriteForwardGetGlobalConsistencyPoint
- IPC:AuroraWriteForwardXactAbort
- IPC:AuroraWriteForwardXactCommit
- IPC:AuroraWriteForwardXactStart

IPC:AuroraWriteForwardConnect

The `IPC:AuroraWriteForwardConnect` event occurs when a backend process on the secondary DB cluster is waiting for a connection to the writer node of the primary DB cluster to be opened.

Likely causes of increased waits

This event increases as the number of connection attempts from a secondary Region's reader node to the writer node of the primary DB cluster increases.

Actions

Reduce the number of simultaneous connections from a secondary node to the primary Region's writer node.

IPC:AuroraWriteForwardConsistencyPoint

The `IPC:AuroraWriteForwardConsistencyPoint` event describes how long a query from a node on the secondary DB cluster will wait for the results of forwarded write operations to be replicated to the current Region. This event is only generated if the session-level parameter `apg_write_forward.consistency_mode` is set to one of the following:

- `SESSION` – queries on a secondary node wait for the results of all changes made in that session.
- `GLOBAL` – queries on a secondary node wait for the results of changes made by that session, plus all committed changes from both the primary Region and other secondary Regions in the global cluster.

For more information about the `apg_write_forward.consistency_mode` parameter settings, see the section called “Configuration parameters for write forwarding in Aurora PostgreSQL”.

Likely causes of increased waits

Common causes for longer wait times include the following:

- Increased replica lag, as measured by the Amazon CloudWatch `ReplicaLag` metric. For more information about this metric, see Monitoring Aurora PostgreSQL replication.
- Increased load on the primary Region's writer node or on the secondary node.

Actions

Change your consistency mode, depending on your application's requirements.

IPC:AuroraWriteForwardExecute

The `IPC:AuroraWriteForwardExecute` event occurs when a backend process on the secondary DB cluster is waiting for a forwarded query to complete and obtain results from the writer node of the primary DB cluster.

Likely causes of increased waits

Common causes for increased waits include the following:

- Fetching a large number of rows from the primary Region's writer node.
- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

We recommend different actions depending on the causes of your wait event.

- Optimize queries to retrieve only necessary data.
- Optimize data manipulation language (DML) operations to only modify necessary data.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardGetGlobalConsistencyPoint

The `IPC:AuroraWriteForwardGetGlobalConsistencyPoint` event occurs when a backend process on the secondary DB cluster that's using the GLOBAL consistency mode is waiting to obtain the global consistency point from the writer node before executing a query.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

We recommend different actions depending on the causes of your wait event.

- Change your consistency mode, depending on your application's requirements.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardXactAbort

The `IPC:AuroraWriteForwardXactAbort` event occurs when a backend process on the secondary DB cluster is waiting for the result of a remote cleanup query. Cleanup queries are issued to return the process to the appropriate state after a write-forwarded transaction is aborted. Amazon Aurora performs them either because an error was found or because an user issued an explicit `ABORT` command or cancelled a running query.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the cleanup query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

We recommend different actions depending on the causes of your wait event.

- Investigate the cause of the aborted transaction.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardXactCommit

The `IPC:AuroraWriteForwardXactCommit` event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded commit transaction command.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardXactStart

The `IPC:AuroraWriteForwardXactStart` event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded start transaction command.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

Using switchover or failover in an Amazon Aurora global database

An Aurora global database provides more business continuity and disaster recovery (BCDR) protection than the standard high availability provided by an Aurora DB cluster in a single AWS Region. By using an Aurora global database, you can plan for and recover from true Regional disasters or complete service-level outages quickly. Recovery from disaster is typically driven by the following two business objectives:

- **Recovery time objective (RTO)** – The time it takes a system to return to a working state after a disaster or service outage. In other words, RTO measures downtime. For an Aurora global database, RTO can be in the order of minutes.
- **Recovery point objective (RPO)** – The amount of data that can be lost (measured in time) after a disaster or service outage. This data loss is usually due to asynchronous replication lag. For an Aurora global database, RPO is typically measured in seconds. With an Aurora PostgreSQL–based global database, you can use the `rds.global_db_rpo` parameter to set and track the upper

bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node. For more information, see Managing RPOs for Aurora PostgreSQL–based global databases.

Switching over or failing over an Aurora global database involves promoting a DB cluster in one of your global database's secondary Regions to be the primary DB cluster. The term "regional outage" is often used to describe a variety of failure scenarios. A worst case scenario could be a wide-spread outage from a catastrophic event that affects hundreds of square miles. However, most outages are much more localized, affecting only a small subset of cloud services or customer systems. Consider the full scope of the outage to make sure cross-Region failover is the proper solution and to choose the appropriate failover method for the situation. Whether you should use the failover or switchover approach depends on the specific outage scenario:

- **Failover –** Use this approach to recover from an unplanned outage. With this approach, you perform a cross-Region failover to one of the secondary DB clusters in your Aurora global database. The RPO for this approach is typically a non-zero value measured in seconds. The amount of data loss depends on the Aurora global database replication lag across the AWS Regions at the time of the failure. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage.
- **Switchover –** This operation was previously called "managed planned failover." Use this approach for controlled scenarios, such as operational maintenance and other planned operational procedures. Because this feature synchronizes secondary DB clusters with the primary before making any other changes, RPO is 0 (no data loss). To learn more, see Performing switchovers for Amazon Aurora global databases.

> **Note**
>
> If you want to switch over or fail over to a headless secondary Aurora DB cluster, you need to first add a DB instance to it. For more information about headless DB clusters, see Creating a headless Aurora DB cluster in a secondary Region.

Topics

Recovering an Amazon Aurora global database from an unplanned outage

On very rare occasions, your Aurora global database might experience an unexpected outage in its primary AWS Region. If this happens, your primary Aurora DB cluster and its writer node aren't available, and the replication between the primary and secondary DB clusters stops. To minimize both downtime (RTO) and data loss (RPO), you can work quickly to perform a cross-Region failover.

There are two methods for failing over in a disaster recovery situation:

- Managed failover – This method is recommended for disaster recovery. When you use this method, Aurora automatically adds back the old primary Region to the global database as a secondary Region when it becomes available again. Thus, the original topology of your global cluster is maintained. To learn how to use this method, see Performing managed failovers for Aurora global databases.
- Manual failover – This alternative method can be used when managed failover isn't an option, for example, when your primary and secondary Regions are running incompatible engine versions. To learn how to use this method, see Performing manual failovers for Aurora global databases.

Important

Both failover methods can result in a loss of write transaction data that wasn't replicated to the chosen secondary before the failover event occurred. However, the recovery process that promotes a DB instance on the chosen secondary DB cluster to be the primary writer DB instance guarantees that the data is in a transactionally consistent state.

Performing managed failovers for Aurora global databases

This approach is intended for business continuity in the event of a true Regional disaster or complete service-level outage.

During a managed failover, your primary cluster is failed over to your choice of secondary Region while your Aurora global database's existing replication topology is maintained. The chosen secondary cluster promotes one of its read-only nodes to full writer status. This step allows the cluster to assume the role of primary cluster. Your database is unavailable for a short time while this cluster is assuming its new role. Data that wasn't replicated from the old primary to the chosen secondary cluster is missing when this secondary becomes the new primary.

> **Note**
>
> You can only perform a managed cross-Region database failover on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different, depending on the minor engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers. If your engine versions are incompatible, you can perform the failover manually by following the steps in Performing manual failovers for Aurora global databases.

To minimize data loss, we recommend that you do the following before using this feature:

- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. Choosing the secondary Region with the least replication lag can minimize data loss with the current failed primary Region. For all Aurora PostgreSQL-based global databases and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher, or 2.12.0 and higher, use Amazon CloudWatch to view the `AuroraGlobalDBRPOLag` metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the `AuroraGlobalDBReplicationLag` metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster.

  For more information about CloudWatch metrics for Aurora, see Cluster-level metrics for Amazon Aurora.

During a managed failover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. Therefore, when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see Modifying parameters for an Aurora global database.

- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms –** Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the failover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a failover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards. For more information about Aurora DB clusters and monitoring, see Overview of monitoring Amazon Aurora.
- **Configure integrations with other AWS services –** If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, you need to make sure these are configured as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see Using Amazon Aurora global databases with other AWS services. To learn more about Secrets Manager, see How to automate replication of secrets in AWS Secrets Manager across AWS Regions.

Typically, the chosen secondary cluster assumes the primary role within a few minutes. As soon as the new primary Region's writer node is available, you can connect your applications to it and resume your workloads. After Aurora promotes the new primary cluster, it automatically rebuilds all additional secondary Region clusters.

Because Aurora global databases use asynchronous replication, the replication lag in each secondary Region can vary. Aurora rebuilds these secondary Regions to have the exact same point-in-time data as the new primary Region cluster. The duration of the complete rebuilding task can take a few minutes to several hours, depending on the size of the storage volume and the distance between the Regions. When the secondary Region clusters finish rebuilding from the new primary Region, they become available for read access.

As soon as the new primary writer is promoted and available, the new primary Region's cluster can handle read and write operations for the Aurora global database. Make sure to change the endpoint for your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-`**`ro`**`-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases.

To restore the global database cluster's original topology, Aurora monitors the availability of the old primary Region. As soon as that Region is healthy and available again, Aurora automatically adds it back to the global cluster as a secondary Region. Before creating the new storage volume in the old primary Region, Aurora tries to take a snapshot of the old storage volume at the point of failure. It does this so that you can use it to recover any of the missing data. If this operation is successful, Aurora places this snapshot named "rds:unplanned-global-failover-*`name-of-old-primary-DB-cluster`*-*`timestamp`*" in the snapshot section of the AWS Management Console. You can also see this snapshot listed in the information returned by the DescribeDBClusterSnapshots API operation.

Note

The snapshot of the old storage volume is a system snapshot that's subject to the backup retention period configured on the old primary cluster. To preserve this snapshot outside of the retention period, you can copy it to save it as a manual snapshot. To learn more about copying snapshots, including pricing, see Copying a DB cluster snapshot.

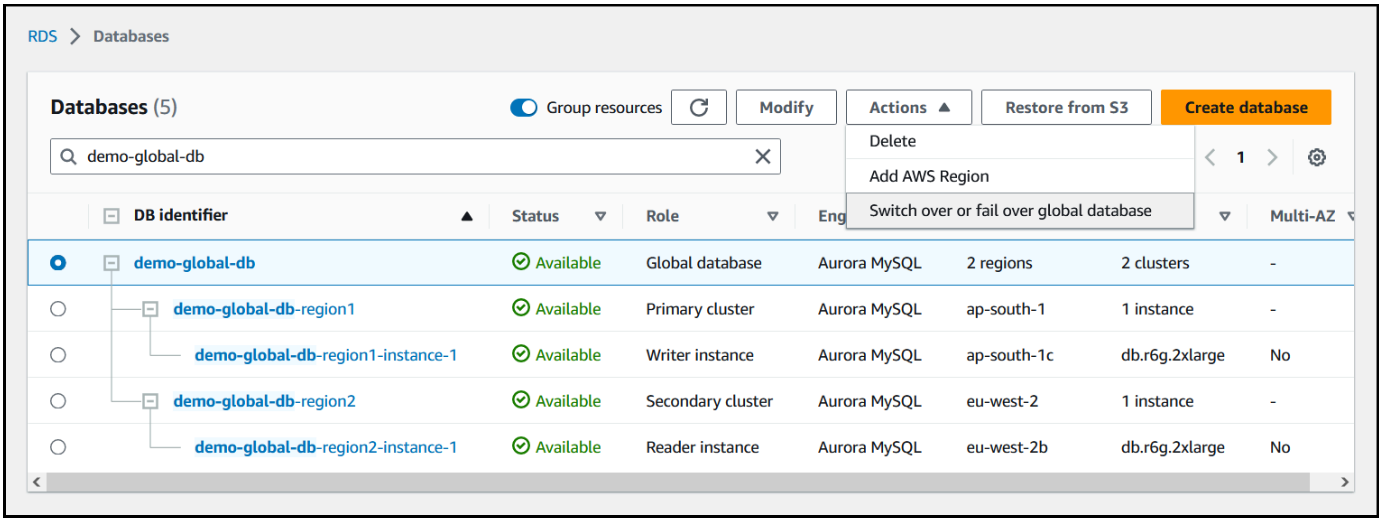
After the original topology is restored, you can fail back your global database to the original primary Region by performing a switchover operation when it makes the most sense for your business and workload. To do so, follow the steps in Performing switchovers for Amazon Aurora global databases.

You can fail over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

Console

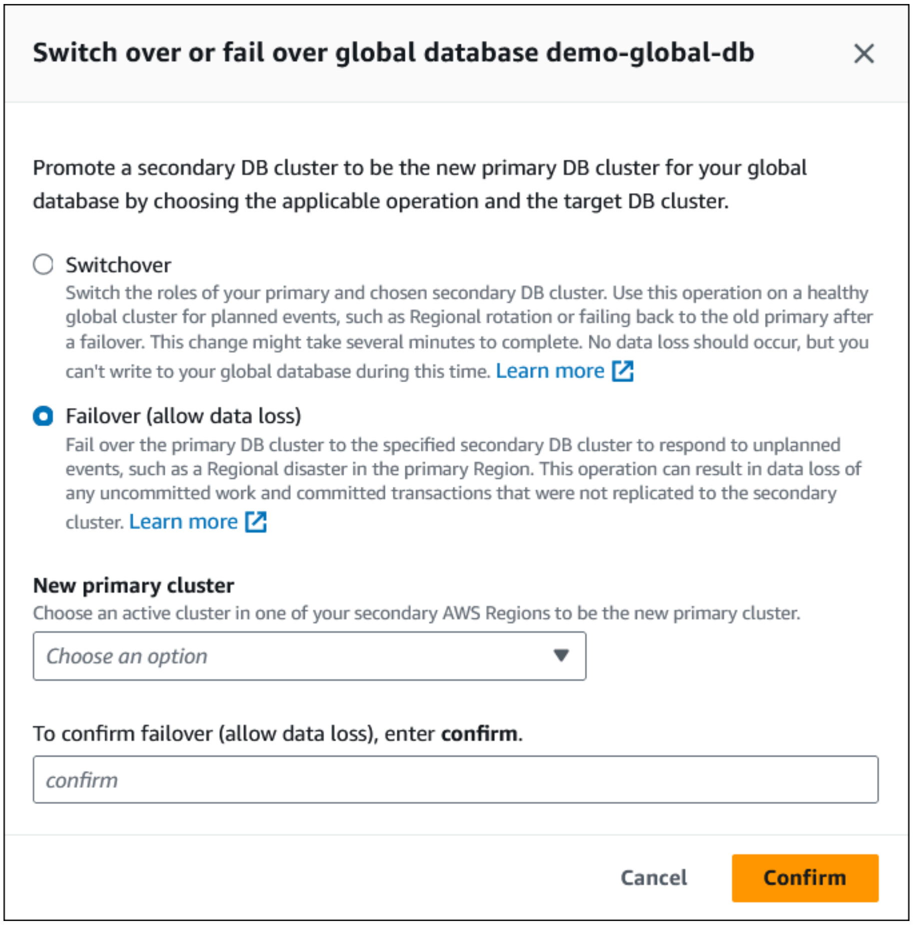
To perform the managed failover on your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** and find the Aurora global database you want to fail over.
3. Choose **Switch over or fail over global database** from the **Actions** menu.



DB identifier	Status	Role	Eng			Multi-AZ
● demo-global-db	Available	Global database	Aurora MySQL	2 regions	2 clusters	-
○ demo-global-db-region1	Available	Primary cluster	Aurora MySQL	ap-south-1	1 instance	-
○ demo-global-db-region1-instance-1	Available	Writer instance	Aurora MySQL	ap-south-1c	db.r6g.2xlarge	No
○ demo-global-db-region2	Available	Secondary cluster	Aurora MySQL	eu-west-2	1 instance	-
○ demo-global-db-region2-instance-1	Available	Reader instance	Aurora MySQL	eu-west-2b	db.r6g.2xlarge	No

4. Choose **Failover (allow data loss)**.



Switch over or fail over global database demo-global-db

Promote a secondary DB cluster to be the new primary DB cluster for your global database by choosing the applicable operation and the target DB cluster.

○ Switchover
Switch the roles of your primary and chosen secondary DB cluster. Use this operation on a healthy global cluster for planned events, such as Regional rotation or failing back to the old primary after a failover. This change might take several minutes to complete. No data loss should occur, but you can't write to your global database during this time. Learn more

● Failover (allow data loss)
Fail over the primary DB cluster to the specified secondary DB cluster to respond to unplanned events, such as a Regional disaster in the primary Region. This operation can result in data loss of any uncommitted work and committed transactions that were not replicated to the secondary cluster. Learn more

New primary cluster
Choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.

Choose an option

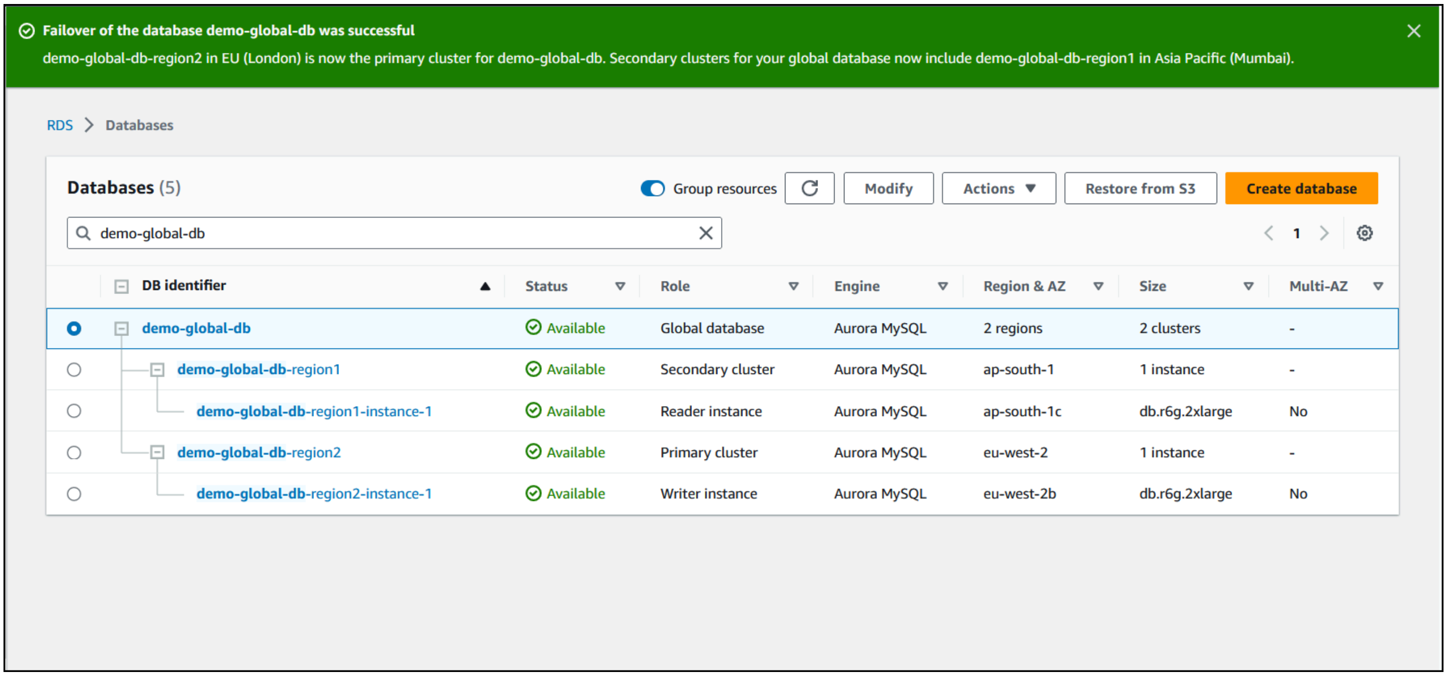
To confirm failover (allow data loss), enter **confirm**.

confirm

5. For **New primary cluster**, choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.

6. Enter **`confirm`**, and then choose **Confirm**.

When the failover completes, you can see the Aurora DB clusters and their current state in the **Databases** list, as shown in the following image.



Failover of the database demo-global-db was successful

demo-global-db-region2 in EU (London) is now the primary cluster for demo-global-db. Secondary clusters for your global database now include demo-global-db-region1 in Asia Pacific (Mumbai).

Databases (5)

	DB identifier	Status	Role	Engine	Region & AZ	Size	Multi-AZ
●	demo-global-db	✓ Available	Global database	Aurora MySQL	2 regions	2 clusters	-
○	demo-global-db-region1	✓ Available	Secondary cluster	Aurora MySQL	ap-south-1	1 instance	-
○	demo-global-db-region1-instance-1	✓ Available	Reader instance	Aurora MySQL	ap-south-1c	db.r6g.2xlarge	No
○	demo-global-db-region2	✓ Available	Primary cluster	Aurora MySQL	eu-west-2	1 instance	-
○	demo-global-db-region2-instance-1	✓ Available	Writer instance	Aurora MySQL	eu-west-2b	db.r6g.2xlarge	No

AWS CLI

To perform the managed failover on an Aurora global database

Use the `failover-global-cluster` CLI command to fail over your Aurora global database. With the command, pass values for the following parameters.

- `--region` – Specify the AWS Region where the secondary DB cluster that you want to be the new primary for the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the new primary for the Aurora global database.
- `--allow-data-loss` – Explicitly make this a failover operation instead of a switchover operation. A failover operation can result in some data loss if the asynchronous replication components haven't completed sending all replicated data to the secondary Region.

For Linux, macOS, or Unix:

```
aws rds --region region_of_selected_secondary \
   failover-global-cluster --global-cluster-identifier global_database_id \
   --target-db-cluster-identifier arn_of_secondary_to_promote \
    --allow-data-loss
```

For Windows:

```
aws rds --region region_of_selected_secondary ^
    failover-global-cluster --global-cluster-identifier global_database_id ^
    --target-db-cluster-identifier arn_of_secondary_to_promote ^
    --allow-data-loss
```

RDS API

To fail over an Aurora global database, run the FailoverGlobalCluster API operation.

Performing manual failovers for Aurora global databases

In some scenarios, you might not be able to use the managed failover process. One example is if your primary and secondary DB clusters aren't running compatible engine versions. In this case, you can follow this manual process to fail over your global database to your target secondary Region.

> **Tip**
>
> We recommend that you understand this process before using it. Have a plan ready to quickly proceed at the first sign of a Region-wide issue. You can be ready to identify the secondary Region with the least replication lag by using Amazon CloudWatch regularly to track lag times for the secondary clusters. Make sure to test your plan to check that your procedures are complete and accurate, and that staff are trained to perform a disaster recovery failover before it really happens.

To manually fail over to a secondary cluster after an unplanned outage in the primary Region

1. Stop issuing DML statements and other write operations to the primary Aurora DB cluster in the AWS Region with the outage.
2. Identify an Aurora DB cluster from a secondary AWS Region to use as a new primary DB cluster. If you have two or more secondary AWS Regions in your Aurora global database, choose the secondary cluster that has the least replication lag.
3. Detach your chosen secondary DB cluster from the Aurora global database.

   Removing a secondary DB cluster from an Aurora global database immediately stops the replication from the primary to this secondary and promotes it to a standalone provisioned

Aurora DB cluster with full read/write capabilities. Any other secondary Aurora DB clusters associated with the primary cluster in the Region with the outage are still available and can accept calls from your application. They also consume resources. Because you're recreating the Aurora global database, remove the other secondary DB clusters before creating the new Aurora global database in the following steps. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

For detailed steps for detaching, see Removing a cluster from an Amazon Aurora global database.

4. Reconfigure your application to send all write operations to this now standalone Aurora DB cluster using its new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the cluster's endpoint string in your application.

   For example, the secondary cluster's endpoint `my-global.cluster-`**`ro`**`-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` when that cluster is detached from the Aurora global database.

   This Aurora DB cluster becomes the primary cluster of a new Aurora global database when you start adding Regions to it in the next step.

   If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases.

5. Add an AWS Region to the DB cluster. When you do this, the replication process from primary to secondary begins. For detailed steps to add a Region, see Adding an AWS Region to an Amazon Aurora global database.

6. Add more AWS Regions as needed to recreate the topology needed to support your application.

Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

If you reconfigured in response to an outage in an AWS Region, you can make that AWS Region the primary again after the outage is resolved. To do so, you add the old AWS Region to your new global database, and then use the switchover process to switch its role. Your Aurora global database must use a version of Aurora PostgreSQL or Aurora MySQL that supports switchovers. For more information, see Performing switchovers for Amazon Aurora global databases.

Performing switchovers for Amazon Aurora global databases

> **Note**
>
> Switchovers were previously called "managed planned failovers."

By using switchovers, you can change the Region of your primary cluster on a routine basis. This approach is intended for controlled scenarios, such as operational maintenance and other planned operational procedures.

There are three common use cases for using switchovers.

- For "regional rotation" requirements imposed on specific industries. For example, financial service regulations might want tier-0 systems to switch to a different Region for several months to ensure that disaster recovery procedures are regularly exercised.
- For multi-Region "follow-the-sun" applications. For example, a business might want to provide lower latency writes in different Regions based on business hours across different time zones.
- As a zero-data-loss method to fail back to the original primary Region after a failover.

> **Note**
>
> Switchovers are designed to be used on a healthy Aurora global database. To recover from an unplanned outage, follow the appropriate procedure in Recovering an Amazon Aurora global database from an unplanned outage.
> To perform a switchover, your target secondary DB cluster must be running the exact same engine version as the primary, including the patch level, depending on the engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers. Before you begin the switchover, check the engine versions in your global cluster to make sure that they support managed cross-Region switchover, and upgrade them if needed.

During a switchover, Aurora switches over your primary cluster to your chosen secondary Region while it maintains your global database's existing replication topology. Before it starts the switchover process, Aurora waits for all secondary Region clusters to be fully synchronized with the primary Region cluster. Then, the DB cluster in the primary Region becomes read-only and the chosen secondary cluster promotes one of its read-only nodes to full writer status. Promoting this node to a writer allows that secondary cluster to assume the role of primary cluster. Because all secondary clusters were synchronized with the primary at the beginning of the process, the new primary continues operations for the Aurora global database without losing any data. Your database is unavailable for a short time while the primary and selected secondary clusters are assuming their new roles.

To optimize application availability, we recommend that you do the following before using this feature:

- Perform this operation during nonpeak hours or at another time when writes to the primary DB cluster are minimal.
- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. For all Aurora PostgreSQL-based global databases and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher or 2.12.0 and higher, use Amazon CloudWatch to view the `AuroraGlobalDBRPOLag` metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the `AuroraGlobalDBReplicationLag` metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster. This value is directly proportional to the time it takes for Aurora to complete the switchover. Therefore, the larger the lag value, the longer the switchover will take.

  For more information about CloudWatch metrics for Aurora, see [Cluster-level metrics for Amazon Aurora](#).

During a switchover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. That means that when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see Modifying parameters for an Aurora global database.
- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the switchover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a switchover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards. For more information about Aurora DB clusters and monitoring, see Overview of monitoring Amazon Aurora.
- **Configure integrations with other AWS services** – If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, make sure to configure your integrations with these services as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see Using Amazon Aurora global databases with other AWS services. To learn more about Secrets Manager, see How to automate replication of secrets in AWS Secrets Manager across AWS Regions.

Note

Typically, the role switchover can take up to several minutes. However, building additional secondary clusters can take a few minutes to several hours, depending on the size of your database and the physical distance between the Regions.

When the switchover process completes, the promoted Aurora DB cluster can handle write operations for the Aurora global database. Make sure to change the endpoint for your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-`**`ro`**`-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases.

You can switch over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

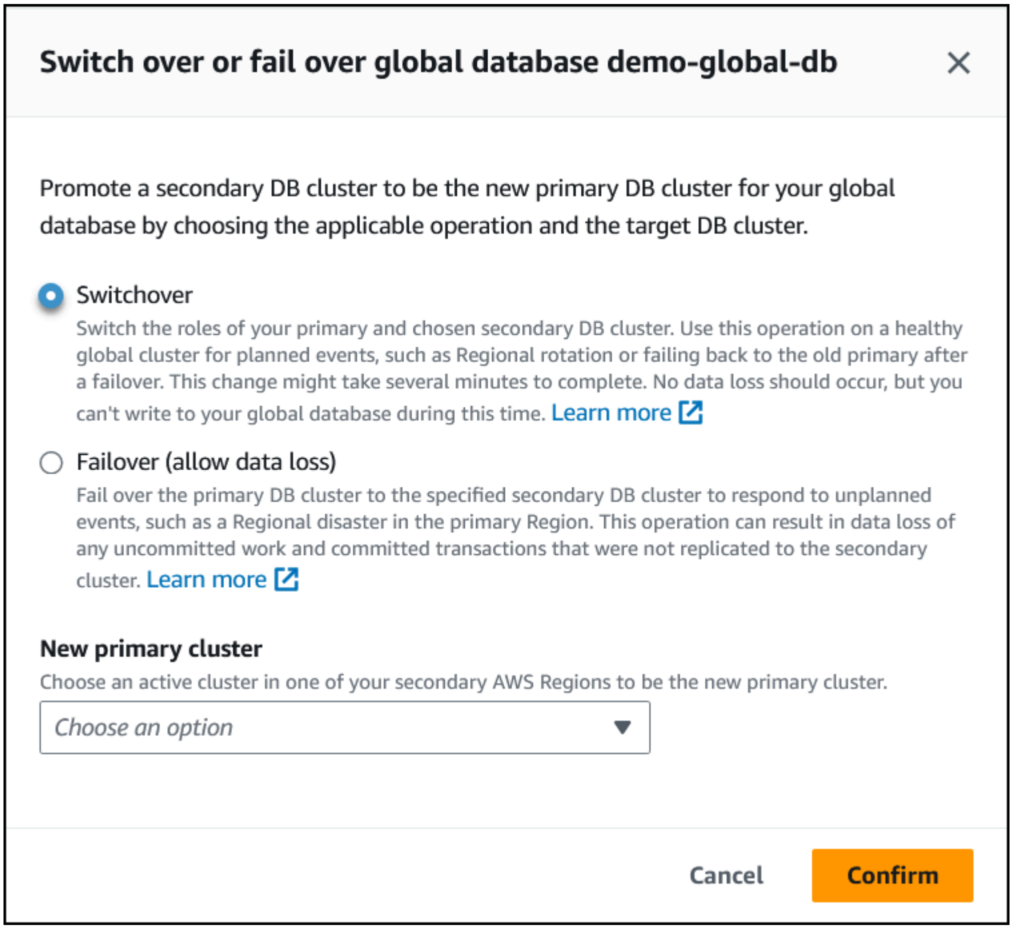
Console

To perform the switchover on your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** and find the Aurora global database you want to switch over.
3. Choose **Switch over or fail over global database** from the **Actions** menu.

	DB identifier	Status	Role	Eng			Multi-AZ
●	demo-global-db	Available	Global database	Aurora MySQL	2 regions	2 clusters	-
○	demo-global-db-region1	Available	Primary cluster	Aurora MySQL	ap-south-1	1 instance	-
○	demo-global-db-region1-instance-1	Available	Writer instance	Aurora MySQL	ap-south-1c	db.r6g.2xlarge	No
○	demo-global-db-region2	Available	Secondary cluster	Aurora MySQL	eu-west-2	1 instance	-
○	demo-global-db-region2-instance-1	Available	Reader instance	Aurora MySQL	eu-west-2b	db.r6g.2xlarge	No

4. Choose **Switchover**.



Switch over or fail over global database demo-global-db

Promote a secondary DB cluster to be the new primary DB cluster for your global database by choosing the applicable operation and the target DB cluster.

● Switchover
Switch the roles of your primary and chosen secondary DB cluster. Use this operation on a healthy global cluster for planned events, such as Regional rotation or failing back to the old primary after a failover. This change might take several minutes to complete. No data loss should occur, but you can't write to your global database during this time. Learn more

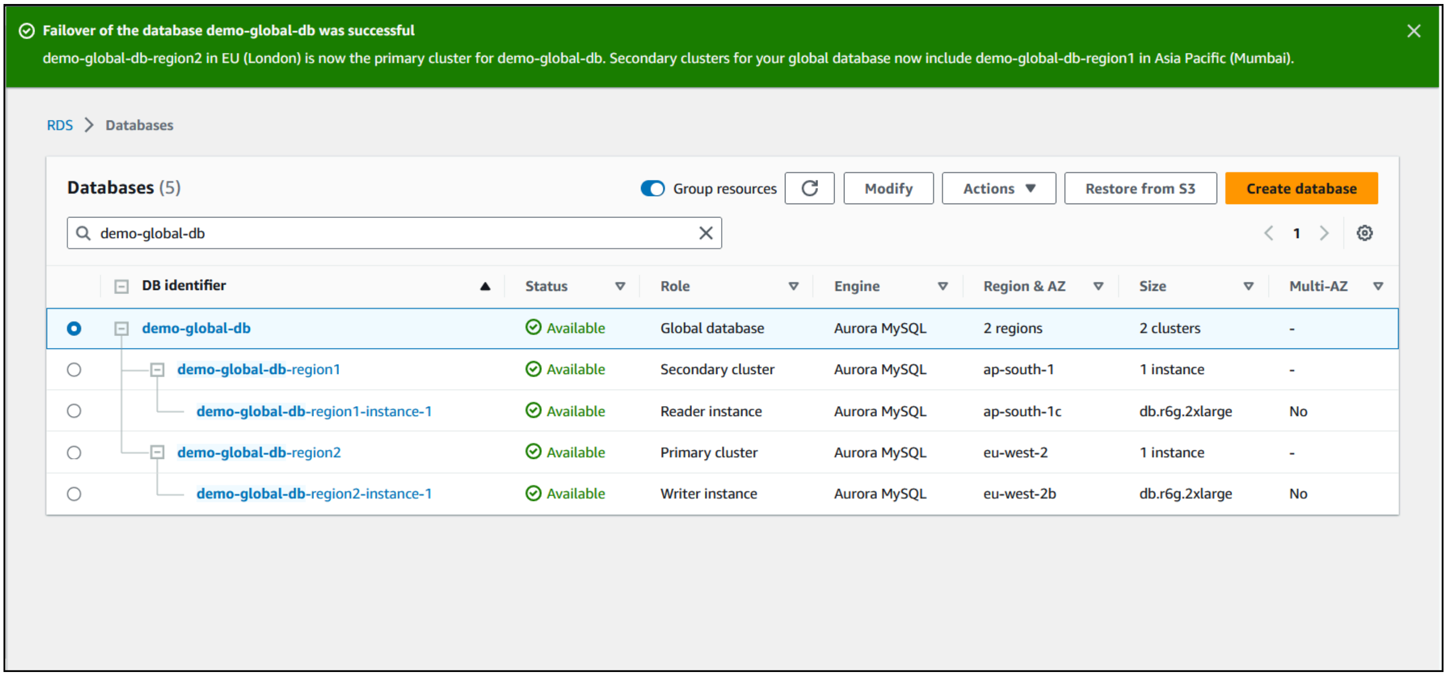
○ Failover (allow data loss)

This operation can result in data loss of any uncommitted work and committed transactions that were not replicated to the secondary cluster. Learn more

New primary cluster
Choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.
Choose an option

5. For **New primary cluster**, choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.
6. Choose **Confirm**.

When the switchover completes, you can see the Aurora DB clusters and their current roles in the **Databases** list, as shown in the following image.



Failover of the database demo-global-db was successful

demo-global-db-region2 in EU (London) is now the primary cluster for demo-global-db. Secondary clusters for your global database now include demo-global-db-region1 in Asia Pacific (Mumbai).

	DB identifier	Status	Role	Engine	Region & AZ	Size	Multi-AZ
●	demo-global-db	Available	Global database	Aurora MySQL	2 regions	2 clusters	-
○	demo-global-db-region1	Available	Secondary cluster	Aurora MySQL	ap-south-1	1 instance	-
○	demo-global-db-region1-instance-1	Available	Reader instance	Aurora MySQL	ap-south-1c	db.r6g.2xlarge	No
○	demo-global-db-region2	Available	Primary cluster	Aurora MySQL	eu-west-2	1 instance	-
○	demo-global-db-region2-instance-1	Available	Writer instance	Aurora MySQL	eu-west-2b	db.r6g.2xlarge	No

AWS CLI

To perform the switchover on an Aurora global database

Use the `switchover-global-cluster` CLI command to switch over your Aurora global database. With the command, pass values for the following parameters.

- `--region` – Specify the AWS Region where the primary DB cluster of the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the primary for the Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region region_of_primary \
   switchover-global-cluster --global-cluster-identifier global_database_id \
  --target-db-cluster-identifier arn_of_secondary_to_promote
```

For Windows:

```
aws rds --region region_of_primary ^
   switchover-global-cluster --global-cluster-identifier global_database_id ^
```

```
    --target-db-cluster-identifier arn_of_secondary_to_promote
```

RDS API

To switch over an Aurora global database, run the SwitchoverGlobalCluster API operation.

Managing RPOs for Aurora PostgreSQL–based global databases

With an Aurora PostgreSQL–based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using the `rds.global_db_rpo` parameter. RPO represents the maximum amount of data that can be lost in the event of an outage.

When you set an RPO for your Aurora PostgreSQL–based global database, Aurora monitors the *RPO lag time* of all secondary clusters to make sure that at least one secondary cluster stays within the target RPO window. RPO lag time is another time-based metric.

The RPO is used when your database resumes operations in a new AWS Region after a failover. Aurora evaluates RPO and RPO lag times to commit (or block) transactions on the primary as follows:

- Commits the transaction if at least one secondary DB cluster has an RPO lag time less than the RPO.
- Blocks the transaction if all secondary DB clusters have RPO lag times that are larger than the RPO. It also logs the event to the PostgreSQL log file and emits "wait" events that show the blocked sessions.

In other words, if all secondary clusters are behind the target RPO, Aurora pauses transactions on the primary cluster until at least one of the secondary clusters catches up. Paused transactions are resumed and committed as soon as the lag time of at least one secondary DB cluster becomes less than the RPO. The result is that no transactions can commit until the RPO is met.

The `rds.global_db_rpo` parameter is dynamic. If you decide that you don't want all write transactions to stall until the lag decreases sufficiently, you can reset it quickly. In this case, Aurora recognizes and implements the change after a short delay.

> **Important**
>
> In a global database with only two Regions, we recommend keeping the `rds.global_db_rpo` parameter's default value in the secondary Region's parameter

group. Otherwise, failing over to this Region due to a loss of the primary Region could cause Aurora to pause transactions. Instead, wait until Aurora completes rebuilding the cluster in the old failed Region before changing this parameter to enforce a maximum RPO.

If you set this parameter as outlined in the following, you can then also monitor the metrics that it generates. You can do so by using `psql` or another tool to query the Aurora global database's primary DB cluster and obtain detailed information about your Aurora PostgreSQL–based global database's operations. To learn how, see Monitoring Aurora PostgreSQL-based global databases.

Topics

- Setting the recovery point objective
- Viewing the recovery point objective
- Disabling the recovery point objective

Setting the recovery point objective

The `rds.global_db_rpo` parameter controls the RPO setting for a PostgreSQL database. This parameter is supported by Aurora PostgreSQL. Valid values for `rds.global_db_rpo` range from 20 seconds to 2,147,483,647 seconds (68 years). Choose a realistic value to meet your business need and use case. For example, you might want to allow up to 10 minutes for your RPO, in which case you set the value to 600.

You can set this value for your Aurora PostgreSQL–based global database by using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To set the RPO

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the primary cluster of your Aurora global database and open the **Configuration** tab to find its DB cluster parameter group. For example, the default parameter group for a primary DB cluster running Aurora PostgreSQL 11.7 is `default.aurora-postgresql11`.

   Parameter groups can't be edited directly. Instead, you do the following:

- Create a custom DB cluster parameter group using the appropriate default parameter group as the starting point. For example, create a custom DB cluster parameter group based on the `default.aurora-postgresql11`.
- On your custom DB parameter group, set the value of the **rds.global_db_rpo** parameter to meet your use case. Valid values range from 20 seconds up to the maximum integer value of 2,147,483,647 (68 years).
- Apply the modified DB cluster parameter group to your Aurora DB cluster.

For more information, see Modifying parameters in a DB cluster parameter group.

AWS CLI

To set the `rds.global_db_rpo` parameter, use the modify-db-cluster-parameter-group CLI command. In the command, specify the name of your primary cluster's parameter group and values for RPO parameter.

The following example sets the RPO to 600 seconds (10 minutes) for the primary DB cluster's parameter group named `my_custom_global_parameter_group`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name my_custom_global_parameter_group \
    --parameters
 "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name my_custom_global_parameter_group ^
    --parameters
 "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

RDS API

To modify the `rds.global_db_rpo` parameter, use the Amazon RDS ModifyDBClusterParameterGroup API operation.

Viewing the recovery point objective

The recovery point objective (RPO) of a global database is stored in the `rds.global_db_rpo` parameter for each DB cluster. You can connect to the endpoint for the secondary cluster you want to view and use `psql` to query the instance for this value.

```
db-name=>show rds.global_db_rpo;
```

If this parameter isn't set, the query returns the following:

```
rds.global_db_rpo
-------------------
 -1
(1 row)
```

This next response is from a secondary DB cluster that has 1 minute RPO setting.

```
rds.global_db_rpo
-------------------
 60
(1 row)
```

You can also use the CLI to get values for find out if `rds.global_db_rpo` is active on any of the Aurora DB clusters by using the CLI to get values of all `user` parameters for the cluster.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
 --db-cluster-parameter-group-name lab-test-apg-global \
 --source user
```

For Windows:

```
aws rds describe-db-cluster-parameters ^
 --db-cluster-parameter-group-name lab-test-apg-global *
 --source user
```

The command returns output similar to the following for all `user` parameters. that aren't `default-engine` or `system` DB cluster parameters.

```
{
    "Parameters": [
        {
            "ParameterName": "rds.global_db_rpo",
            "ParameterValue": "60",
            "Description": "(s) Recovery point objective threshold, in seconds, that
 blocks user commits when it is violated.",
            "Source": "user",
            "ApplyType": "dynamic",
            "DataType": "integer",
            "AllowedValues": "20-2147483647",
            "IsModifiable": true,
            "ApplyMethod": "immediate",
            "SupportedEngineModes": [
                "provisioned"
            ]
        }
    ]
}
```

To learn more about viewing parameters of the cluster parameter group, see Viewing parameter values for a DB cluster parameter group.

Disabling the recovery point objective

To disable the RPO, reset the `rds.global_db_rpo` parameter. You can reset parameters using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To disable the RPO

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose your primary DB cluster parameter group.
4. Choose **Edit parameters**.
5. Choose the box next to the **rds.global_db_rpo** parameter.
6. Choose **Reset**.
7. When the screen shows **Reset parameters in DB parameter group**, choose **Reset parameters**.

For more information on how to reset a parameter with the console, see Modifying parameters in a DB cluster parameter group.

AWS CLI

To reset the `rds.global_db_rpo` parameter, use the reset-db-cluster-parameter-group command.

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
    --db-cluster-parameter-group-name global_db_cluster_parameter_group \
    --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name global_db_cluster_parameter_group ^
    --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

RDS API

To reset the `rds.global_db_rpo` parameter, use the Amazon RDS API ResetDBClusterParameterGroup operation.

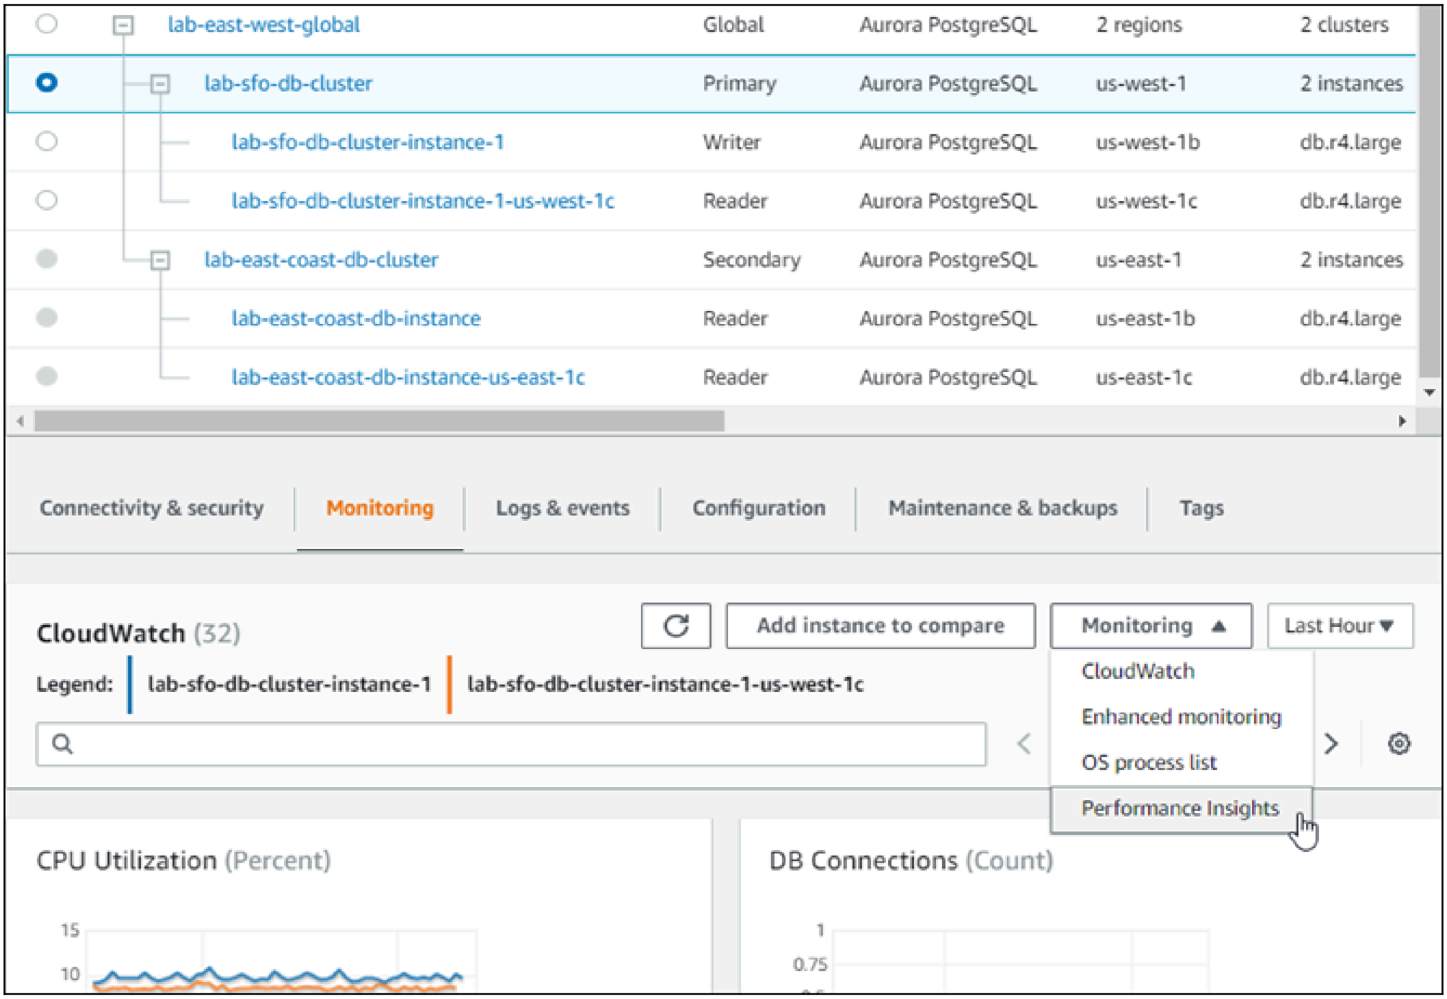
Monitoring an Amazon Aurora global database

When you create the Aurora DB clusters that make up your Aurora global database, you can choose many options that let you monitor your DB cluster's performance. These options include the following:

- Amazon RDS Performance Insights – Enables performance schema in the underlying Aurora database engine. To learn more about Performance Insights and Aurora global databases, see Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights.
- Enhanced monitoring – Generates metrics for process or thread utilization on the CPU. To learn about enhanced monitoring, see Monitoring OS metrics with Enhanced Monitoring.
- Amazon CloudWatch Logs – Publishes specified log types to CloudWatch Logs. Error logs are published by default, but you can choose other logs specific to your Aurora database engine.

  - For Aurora MySQL–based Aurora DB clusters, you can export the audit log, general log, and slow query log.
  - For Aurora PostgreSQL–based Aurora DB clusters, you can export the PostgreSQL log.
- For Aurora MySQL–based global databases, you can query specific `information_schema` tables to check the status of your Aurora global database and its instances. To learn how, see Monitoring Aurora MySQL-based global databases.
- For Aurora PostgreSQL–based global databases, you can use specific functions to check the status of your Aurora global database and its instances. To learn how, see Monitoring Aurora PostgreSQL-based global databases.

The following screenshot shows some of the options available on the Monitoring tab of a primary Aurora DB cluster in an Aurora global database.



○	lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters
●	lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances
○	lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large
○	lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances
○	lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large
○	lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large

For more information, see Monitoring metrics in an Amazon Aurora cluster.

Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights

You can use Amazon RDS Performance Insights for your Aurora global databases. You enable this feature individually, for each Aurora DB cluster in your Aurora global database. To do so, you choose **Enable Performance Insights** in the **Additional configuration** section of the Create database page. Or you can modify your Aurora DB clusters to use this feature after they are up and running. You can enable or turn off Performance Insights for each cluster that's part of your Aurora global database.

The reports created by Performance Insights apply to each cluster in the global database. When you add a new secondary AWS Region to an Aurora global database that's already using Performance Insights, be sure that you enable Performance Insights in the newly added cluster. It doesn't inherit the Performance Insights setting from the existing global database.

You can switch AWS Regions while viewing the Performance Insights page for a DB instance that's attached to a global database. However, you might not see performance information immediately after switching AWS Regions. Although the DB instances might have identical names in each AWS Region, the associated Performance Insights URL is different for each DB instance. After switching AWS Regions, choose the name of the DB instance again in the Performance Insights navigation pane.

For DB instances associated with a global database, the factors affecting performance might be different in each AWS Region. For example, the DB instances in each AWS Region might have different capacity.

To learn more about using Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora.

Monitoring Aurora global databases with Database Activity Streams

By using the Database Activity Streams feature, you can monitor and set alarms for auditing activity in the DB clusters in your global database. You start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region. For more information, see Monitoring Amazon Aurora with Database Activity Streams.

Monitoring Aurora MySQL-based global databases

To view the status of an Aurora MySQL-based global database, query the information_schema.aurora_global_db_status and information_schema.aurora_global_db_instance_status tables.

> **Note**
>
> The `information_schema.aurora_global_db_status` and `information_schema.aurora_global_db_instance_status` tables are only available with Aurora MySQL version 3.04.0 and higher global databases.

To monitor an Aurora MySQL-based global database

1. Connect to the global database primary cluster endpoint using a MySQL client. For more information about how to connect, see Connecting to an Amazon Aurora global database.
2. Query the `information_schema.aurora_global_db_status` table in a mysql command to list the primary and secondary volumes. This query returns the lag times of the global database secondary DB clusters, as in the following example.

   ```
   mysql> select * from information_schema.aurora_global_db_status;
   ```

   ```
   AWS_REGION | HIGHEST_LSN_WRITTEN | DURABILITY_LAG_IN_MILLISECONDS |
    RPO_LAG_IN_MILLISECONDS | LAST_LAG_CALCULATION_TIMESTAMP | OLDEST_READ_VIEW_TRX_ID
   -----------+---------------------+---------------------------------
   +------------------------+---------------------------------
   +------------------------
   us-east-1  |           183537946 |                              0   |
         0 |  1970-01-01 00:00:00.000000     |               0
   us-west-2  |           183537944 |                              428 |
         0 |  2023-02-18 01:26:41.925000     |               20806982
   (2 rows)
   ```

   The output includes a row for each DB cluster of the global database containing the following columns:

   - **AWS_REGION** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see Regions and Availability Zones.

- **HIGHEST_LSN_WRITTEN** – The highest log sequence number (LSN) currently written on this DB cluster.

  A *log sequence number (LSN)* is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- **DURABILITY_LAG_IN_MILLISECONDS** – The difference in the timestamp values between the HIGHEST_LSN_WRITTEN on a secondary DB cluster and the HIGHEST_LSN_WRITTEN on the primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.
- **RPO_LAG_IN_MILLISECONDS** – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database.

  In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.
- **LAST_LAG_CALCULATION_TIMESTAMP** – The timestamp that specifies when values were last calculated for DURABILITY_LAG_IN_MILLISECONDS and RPO_LAG_IN_MILLISECONDS. A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.
- **OLDEST_READ_VIEW_TRX_ID** – The ID of the oldest transaction that the writer DB instance can purge to.

3. Query the information_schema.aurora_global_db_instance_status table to list all secondary DB instances for both the primary DB cluster and the secondary DB clusters.

```
mysql> select * from information_schema.aurora_global_db_instance_status;
```

```
SERVER_ID            |              SESSION_ID              | AWS_REGION
 | DURABLE_LSN | HIGHEST_LSN_RECEIVED | OLDEST_READ_VIEW_TRX_ID |
 OLDEST_READ_VIEW_LSN | VISIBILITY_LAG_IN_MSEC
---------------------+--------------------------------------+------------
+-------------+----------------------+------------------------
+----------------------+------------------------
```

```
ams-gdb-primary-i2   | MASTER_SESSION_ID                    | us-east-1  |
 183537698   |                    0 |                       0 |
 0 |                      0
ams-gdb-secondary-i1 | cc43165b-bdc6-4651-abbf-4f74f08bf931 | us-west-2  |
 183537689   |            183537692 |                20806928 |
 183537682 |                      0
ams-gdb-secondary-i2 | 53303ff0-70b5-411f-bc86-28d7a53f8c19 | us-west-2  |
 183537689   |            183537692 |                20806928 |
 183537682 |                    677
ams-gdb-primary-i1   | 5af1e20f-43db-421f-9f0d-2b92774c7d02 | us-east-1  |
 183537697   |            183537698 |                20806930 |
 183537691 |                     21
(4 rows)
```

The output includes a row for each DB instance of the global database containing the following columns:

- **SERVER_ID** – The server identifier for the DB instance.
- **SESSION_ID** – A unique identifier for the current session. A value of `MASTER_SESSION_ID` identifies the Writer (primary) DB instance.
- **AWS_REGION** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).
- **DURABLE_LSN** – The LSN made durable in storage.
- **HIGHEST_LSN_RECEIVED** – The highest LSN received by the DB instance from the writer DB instance.
- **OLDEST_READ_VIEW_TRX_ID** – The ID of the oldest transaction that the writer DB instance can purge to.
- **OLDEST_READ_VIEW_LSN** – The oldest LSN used by the DB instance to read from storage.
- **VISIBILITY_LAG_IN_MSEC** – For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
mysql> BEGIN;
mysql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
mysql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the BEGIN statement. If so, the secondary DB cluster's **DURABILITY_LAG_IN_MILLISECONDS** value starts increasing. At the end of the INSERT statement, the **DURABILITY_LAG_IN_MILLISECONDS** value is 1 hour. However, the **RPO_LAG_IN_MILLISECONDS** value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the COMMIT statement completes, the **RPO_LAG_IN_MILLISECONDS** value increases.

Monitoring Aurora PostgreSQL-based global databases

To view the status of an Aurora PostgreSQL-based global database, use the aurora_global_db_status and aurora_global_db_instance_status functions.

Note

Only Aurora PostgreSQL supports the aurora_global_db_status and aurora_global_db_instance_status functions.

To monitor an Aurora PostgreSQL-based global database

1. Connect to the global database primary cluster endpoint using a PostgreSQL utility such as psql. For more information about how to connect, see Connecting to an Amazon Aurora global database.
2. Use the aurora_global_db_status function in a psql command to list the primary and secondary volumes. This shows the lag times of the global database secondary DB clusters.

```
postgres=> select * from aurora_global_db_status();
```

```
aws_region | highest_lsn_written | durability_lag_in_msec | rpo_lag_in_msec |
 last_lag_calculation_time  | feedback_epoch | feedback_xmin
------------+---------------------+------------------------+-----------------
+----------------------------+----------------+---------------
us-east-1  |         93763984222 |                     -1 |              -1 |
 1970-01-01 00:00:00+00     |              0 |             0
us-west-2  |         93763984222 |                    900 |            1090 |
 2020-05-12 22:49:14.328+00 |              2 |    3315479243
```

```
(2 rows)
```

The output includes a row for each DB cluster of the global database containing the following columns:

- **aws_region** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see Regions and Availability Zones.
- **highest_lsn_written** – The highest log sequence number (LSN) currently written on this DB cluster.

  A *log sequence number (LSN)* is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- **durability_lag_in_msec** – The timestamp difference between the highest log sequence number written on a secondary DB cluster (`highest_lsn_written`) and the `highest_lsn_written` on the primary DB cluster.
- **rpo_lag_in_msec** – The recovery point objective (RPO) lag. This lag is the time difference between the most recent user transaction commit stored on a secondary DB cluster and the most recent user transaction commit stored on the primary DB cluster.
- **last_lag_calculation_time** – The timestamp when values were last calculated for `durability_lag_in_msec` and `rpo_lag_in_msec`.
- **feedback_epoch** – The epoch a secondary DB cluster uses when it generates hot standby information.

  Hot standby is when a DB cluster can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB cluster when it's in hot standby. For more information, see Hot standby in the PostgreSQL documentation.
- **feedback_xmin** – The minimum (oldest) active transaction ID used by a secondary DB cluster.

3. Use the `aurora_global_db_instance_status` function to list all secondary DB instances for both the primary DB cluster and secondary DB clusters.

```
postgres=> select * from aurora_global_db_instance_status();
```

```
server_id                                   |              session_id
  | aws_region | durable_lsn | highest_lsn_rcvd | feedback_epoch | feedback_xmin |
 oldest_read_view_lsn | visibility_lag_in_msec
--------------------------------------------+--------------------------------------
+------------+-------------+------------------+----------------+--------------
+----------------------+-----------------------
apg-global-db-rpo-mammothrw-elephantro-1-n1 | MASTER_SESSION_ID
 | us-east-1  | 93763985102 |                  |                |               |
                    |
apg-global-db-rpo-mammothrw-elephantro-1-n2 | f38430cf-6576-479a-b296-dc06b1b1964a
 | us-east-1  | 93763985099 |      93763985102 |              2 |    3315479243 |
        93763985095 |                     10
apg-global-db-rpo-elephantro-mammothrw-n1   | 0d9f1d98-04ad-4aa4-8fdd-e08674cbbbfe
 | us-west-2  | 93763985095 |      93763985099 |              2 |    3315479243 |
        93763985089 |                   1017
(3 rows)
```

The output includes a row for each DB instance of the global database containing the following columns:

- **server_id** – The server identifier for the DB instance.
- **session_id** – A unique identifier for the current session.
- **aws_region** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see Regions and Availability Zones.
- **durable_lsn** – The LSN made durable in storage.
- **highest_lsn_rcvd** – The highest LSN received by the DB instance from the writer DB instance.
- **feedback_epoch** – The epoch the DB instance uses when it generates hot standby information.

  Hot standby is when a DB instance can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB instance when it's in hot standby. For more information, see the PostgreSQL documentation on Hot standby.
- **feedback_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
- **oldest_read_view_lsn** – The oldest LSN used by the DB instance to read from storage.
- **visibility_lag_in_msec** – How far this DB instance is lagging behind the writer DB instance.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
psql> BEGIN;
psql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
psql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the `BEGIN` statement. If so, the secondary DB cluster's `durability_lag_in_msec` value starts increasing. At the end of the `INSERT` statement, the `durability_lag_in_msec` value is 1 hour. However, the `rpo_lag_in_msec` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the `COMMIT` statement completes, the `rpo_lag_in_msec` value increases.

Using Amazon Aurora global databases with other AWS services

You can use your Aurora global databases with other AWS services, such as Amazon S3 and AWS Lambda. Doing so requires that all Aurora DB clusters in your global database have the same privileges, external functions, and so on in the respective AWS Regions. Because a read-only Aurora secondary DB cluster in an Aurora global database can be promoted to the role of primary, we recommend that you set up write privileges ahead of time, on all Aurora DB clusters for any services you plan to use with your Aurora global database.

The following procedures summarize the actions to take for each AWS service.

To invoke AWS Lambda functions from an Aurora global database

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in Invoking a Lambda function from an Amazon Aurora MySQL DB cluster.
2. For each cluster in the Aurora global database, set the (ARN) of the new IAM (IAM) role.
3. To permit database users in an Aurora global database to invoke Lambda functions, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services with each cluster in the Aurora global database.
4. Configure each cluster in the Aurora global database to allow outbound connections to Lambda. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services.

To load data from Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket.
2. For each Aurora cluster in the global database, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services.

To save queried data to Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket.
2. For each Aurora cluster in the global database, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services.

Upgrading an Amazon Aurora global database

Upgrading an Aurora global database follows the same procedures as upgrading Aurora DB clusters. However, following are some important differences to take note of before you start the process.

We recommend that you upgrade the primary and secondary DB clusters to the same version. You can only perform a managed cross-Region database failover on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different, depending on the minor engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers.

Major version upgrades

When you perform a major version upgrade of an Amazon Aurora global database, you upgrade the global database cluster instead the individual clusters that it contains.

To learn how to upgrade an Aurora PostgreSQL global database to a higher major version, see Major upgrades for global databases.

Note

With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see Managing RPOs for Aurora PostgreSQL–based global databases.

To learn how to upgrade an Aurora MySQL global database to a higher major version, see In-place major upgrades for global databases.

Note

With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on.
To perform a major version upgrade to Aurora MySQL version 3 when using `lower_case_table_names`, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in Removing a cluster from an Amazon Aurora global database.
2. Upgrade the engine version of the primary Region to Aurora MySQL version 3. Follow the steps in How to perform an in-place upgrade.
3. Add secondary Regions to the global cluster. Follow the steps in Adding an AWS Region to an Amazon Aurora global database.

You can also use the snapshot restore method instead. For more information, see Restoring from a DB cluster snapshot.

Minor version upgrades

For a minor upgrade on an Aurora global database, you upgrade all of the secondary clusters before you upgrade the primary cluster.

To learn how to upgrade an Aurora PostgreSQL global database to a higher minor version, see How to perform minor version upgrades and apply patches. To learn how to upgrade an Aurora MySQL global database to a higher minor version, see Upgrading Aurora MySQL by modifying the engine version.

Before you perform the upgrade, review the following considerations:

- Upgrading the minor version of a secondary cluster doesn't affect availability or usage of the primary cluster in any way.
- A secondary cluster must have at least one DB instance to perform a minor upgrade.
- If you upgrade an Aurora MySQL global database to version 2.11.*, you must upgrade your primary and secondary DB clusters to the exact same version, including the patch level.
- To support managed cross-Region switchovers or failovers, you must upgrade your primary and secondary DB clusters to the exact same version, including the patch level, depending on the engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers.

Patch level compatibility for managed cross-Region switchovers and failovers

When you upgrade your Aurora global database to one of the following minor engine versions, you can perform managed cross-Region switchovers or failovers even if the patch levels of your primary and secondary DB clusters don't match. For minor engine versions lower than the ones on this list, you must upgrade your primary and secondary DB clusters to the same major, minor, and patch levels to perform managed cross-Region switchovers or failovers. Make sure to review the version information and the notes in the following table.

> **Note**
>
> For manual cross-Region failovers, you can perform the failover process as long as the target secondary DB cluster is running the same major and minor engine version as the primary DB cluster. In this case, the patch levels don't need to match.

Database engine	Minor engine versions	Notes
Aurora MySQL	No minor versions	With all minor versions, you can perform managed cross-Region switchovers or failovers only if the patch levels of the primary and secondary DB clusters match.
Aurora PostgreSQL	• Version 14.5 or higher minor version • Version 13.8 or higher minor version • Version 12.12 or higher minor version • Version 11.17 or higher minor version	With the minor engine versions listed in the previous column, you can perform managed cross-Reg ion switchovers or failovers from a primary DB cluster with one patch level to a secondary DB cluster with a different patch level. With minor versions lower than these, you can perform managed cross-Region switchovers or failovers only if the patch levels of the

Database engine	Minor engine versions	Notes
		primary and secondary DB clusters match.

Using Amazon RDS Proxy for Aurora

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or new connections being created at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect a database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the connection pool. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that RDS can serve with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes. For a list of supported engine versions, see Supported Regions and Aurora DB engines for Amazon RDS Proxy.

Topics

- Working with Amazon RDS Proxy endpoints
- Monitoring RDS Proxy metrics with Amazon CloudWatch
- Working with RDS Proxy events
- RDS Proxy command-line examples
- Troubleshooting for RDS Proxy
- Using RDS Proxy with AWS CloudFormation
- Using RDS Proxy with Aurora global databases

Region and version availability

For information about database engine version support and availability of RDS Proxy in a given AWS Region, see Supported Regions and Aurora DB engines for Amazon RDS Proxy.

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- Each AWS account ID is limited to 20 proxies. If your application requires more proxies, request an increase via the **Service Quotas** page within the AWS Management Console. In the **Service Quotas** page, select **Amazon Relational Database Service (Amazon RDS)** and locate **Proxies** to request a quota increase. AWS can automatically increase your quota or pending review of your request by AWS Support.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to with up to 200 different user accounts at any given time.
- Each proxy has a default endpoint. You can also add up to 20 proxy endpoints for each proxy. You can create, view, modify, and delete these endpoints.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see Overview of proxy endpoints.
- You can use RDS Proxy with Aurora Serverless v2 clusters, but not with Aurora Serverless v1 clusters.

- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping your database on a local host, you can't connect to your proxy unless you set up the necessary network requirements to allow connection to the proxy. This is because your local host is outside of the proxy's VPC.

  > **Note**
  >
  > For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see Accessing Aurora databases across VPCs.

- You can't use RDS Proxy with a VPC that has its tenancy set to `dedicated`.
- If you use RDS Proxy with an Aurora DB cluster that has IAM authentication enabled, check user authentication. Users who connect through a proxy must authenticate through sign-in credentials. For details about Secrets Manager and IAM support in RDS Proxy, see Setting up database credentials in AWS Secrets Manager and Setting up AWS Identity and Access Management (IAM) policies.
- You can't use RDS Proxy with custom DNS when using SSL hostname validation.
- Each proxy can be associated with a single target DB cluster. However, you can associate multiple proxies with the same DB cluster.
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.
- Certain Regions have Availability-Zone (AZ) restrictions to consider while creating your proxy. US East (N. Virginia) Region does not support RDS Proxy in the `use1-az3` Availability Zone. US West (N. California) Region does not support RDS Proxy in the `usw1-az2` Availability Zone. When selecting subnets while creating your proxy, make sure that you don't select subnets in the Availability Zones mentioned above.
- Currently, RDS Proxy doesn't support any global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.

For additional limitations for each DB engine, see the following sections:

- Additional limitations for Aurora MySQL

- Additional limitations for Aurora PostgreSQL

Additional limitations for Aurora MySQL

The following additional limitations apply to RDS Proxy with Aurora MySQL databases:

- RDS Proxy doesn't support the MySQL `sha256_password` and `caching_sha2_password` authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to `1`.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
- Some SQL statements and functions such as `SET LOCAL` can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning.
- Using the `ROW_COUNT()` function in a multi-statement query is not supported.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.

> ⚠ **Important**
>
> For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for Aurora PostgreSQL

The following additional limitations apply to RDS Proxy with Aurora PostgreSQL databases:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case, for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
- The results of the PostgreSQL function lastval aren't always accurate. As a work-around, use the INSERT statement with the `RETURNING` clause.
- RDS Proxy currently doesn't support streaming replication mode.

> ⚠ **Important**
>
> For existing proxies with PostgreSQL databases, if you modify the database authentication to use `SCRAM` only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:
>
> - Ensure that the database allows both `SCRAM` and `MD5` authentication.
> - To use only `SCRAM` authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. This is often characterized by a high value of the `ConnectionAttempts` CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB cluster.
- For DB clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch

metrics to determine whether a DB cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB cluster.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB clusters. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Aurora Multi-AZ databases. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your Aurora DB cluster. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

Topics

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the **Proxies** page.

Each proxy handles connections to a single Aurora DB cluster. The proxy automatically determines the current writer instance for Aurora provisioned clusters.

The connections that a proxy keeps open and available for your database applications to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an Amazon Aurora DB cluster. You do so instead of connecting to the read/write endpoint that connects directly to the cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see Overview of proxy endpoints.

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within a cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The Aurora DB cluster associated with a proxy are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated Aurora DB. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see Security in Amazon Aurora. Also, make sure to familiarize yourself with how Aurora work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.3, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role. This is so even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

> **Note**
>
> RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy in the AWS Management Console.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, 1.2, and 1.3. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode` `VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For the `.pem` file to use, download all root CA PEMs from Amazon Trust Services and place them into a single `.pem` file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your applications more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. This helps speed up and simplify the failover process. This is less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on the database in failover. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the Aurora MySQL `autocommit` setting is turned on.
- Conversely, when the `autocommit` setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see Avoiding pinning.

Getting started with RDS Proxy

Use the information in the following pages to set up and manage Using Amazon RDS Proxy for Auroraand set related security options. The security options control who can access each proxy and how each proxy connects to DB instances.

If you're new to RDS Proxy, we recommend following the pages in the order that we present them.

Topics

- Setting up network prerequisites
- Setting up database credentials in AWS Secrets Manager
- Setting up AWS Identity and Access Management (IAM) policies
- Creating an RDS Proxy
- Viewing an RDS Proxy
- Connecting to a database through RDS Proxy

Setting up network prerequisites

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see Work with shared VPCs.

Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any Aurora DB clusters, you already have the required network resources.

Topics

- Getting information about your subnets
- Planning for IP address capacity

Getting information about your subnets

If you're just getting started with Aurora, you can learn the basics of connecting to a database by following the procedures in Setting up your environment for Amazon Aurora. You can also follow the tutorial in Getting started with Amazon Aurora.

To create a proxy, you must provide the subnets and the VPC that the proxy operates within. The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster.

For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance. To do so, examine the nested fields within the `DBSubnetGroup` and `Subnets` attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Find the ID of any DB instance in the cluster.
$  aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[].
[DBClusterMembers]|[0]|[0][*].DBInstanceIdentifier' --output text
```

```
my_instance_id
instance_id_2
instance_id_3
```

After finding the DB instance identifier, examine the associated VPC to find its subnets. The following Linux example shows how.

```
$ #From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
 IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]|[0]|[0]|[Subnets]|[0]|[*].SubnetIdentifier' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
...
```

```
$ #From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]|[0]|[0].VpcId' --output text
```

```
my_vpc_id
```

```
$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].
[SubnetId]' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity such as increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event `RDS-EVENT-0243` when there aren't enough free IP addresses in your subnets. For information about this event, see Working with RDS Proxy events.

Following are the recommended minimum numbers of IP addresses to leave free in your subnets for your proxy based on DB instance class sizes.

DB instance class	Minimum free IP addresses
db.*.xlarge or smaller	10
db.*.2xlarge	15
db.*.4xlarge	25
db.*.8xlarge	45

DB instance class	Minimum free IP addresses
db.*.12xlarge	60
db.*.16xlarge	75
db.*.24xlarge	110

These recommended numbers of IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

> **Note**
>
> RDS Proxy doesn't support more than 215 IP addresses in a VPC.

For example, suppose that you want to estimate the required IP addresses for a proxy that's associated with an Aurora DB cluster.

In this case, assume the following:

- Your Aurora DB cluster has 1 writer instance of size db.r5.8xlarge and 1 reader instance of size db.r5.2xlarge.
- The proxy that's attached to this DB cluster has the default endpoint and 1 custom endpoint with the read-only role.

In this case, the proxy needs approximately 63 free IP addresses (45 for the writer instance, 15 for reader instance, and 3 for the additional custom endpoint).

Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the Aurora DB cluster.

In Secrets Manager console, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on a Aurora DB cluster that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

To connect through the proxy as a specific database user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret]() page in the Secrets Manager documentation. Use one of the following techniques:

- Use [Secrets Manager]() in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

  ```
  aws secretsmanager create-secret
    --name "secret_name"
    --description "secret_description"
    --region region_name
    --secret-string '{"username":"db_user","password":"db_user_password"}'
  ```

- You can also create a custom key to encrypt your Secrets Manager secret. The following command creates an example key.

  ```
  PREFIX=my_identifier
  aws kms create-key --description "$PREFIX-test-key" --policy '{
    "Id":"$PREFIX-kms-policy",
    "Version":"2012-10-17",
  ```

```
  "Statement":
    [
      {
        "Sid":"Enable IAM User Permissions",
        "Effect":"Allow",
        "Principal":{"AWS":"arn:aws:iam::account_id:root"},
        "Action":"kms:*","Resource":"*"
      },
      {
        "Sid":"Allow access for Key Administrators",
        "Effect":"Allow",
        "Principal":
          {
            "AWS":
              ["$USER_ARN","arn:aws:iam:account_id::role/Admin"]
          },
        "Action":
          [
            "kms:Create*",
            "kms:Describe*",
            "kms:Enable*",
            "kms:List*",
            "kms:Put*",
            "kms:Update*",
            "kms:Revoke*",
            "kms:Disable*",
            "kms:Get*",
            "kms:Delete*",
            "kms:TagResource",
            "kms:UntagResource",
            "kms:ScheduleKeyDeletion",
            "kms:CancelKeyDeletion"
          ],
        "Resource":"*"
      },
      {
        "Sid":"Allow use of the key",
        "Effect":"Allow",
        "Principal":{"AWS":"$ROLE_ARN"},
        "Action":["kms:Decrypt","kms:DescribeKey"],
        "Resource":"*"
      }
    ]
```

```
}'
```

For example, the following commands create Secrets Manager secrets for two database users:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To create these secrets encrypted with your custom AWS KMS key, use the following commands:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for *`your_secret_name`*.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM, see Identity and access management for Amazon Aurora.

> **Tip**
>
> The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the **Create role** process, as described in Creating IAM roles, choosing Creating a role to delegate permissions to an AWS service.

   Choose **AWS service** for the **Trusted entity type**. Under **Use case**, select **RDS** from **Use cases for other AWS services** dropdown. Select **RDS - Add Role to Database**.

2. For the new role, perform the **Add inline policy** step. Use the same general procedures as in Editing IAM policies. Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for `us-east-2`. Substitute the Amazon Resource Names (ARNs) for the secrets that you created, see Specifying KMS keys in IAM policy statements. For the `kms:Decrypt` action, substitute the ARN of the default AWS KMS key or your own KMS key. Which one you use depends on which one you used to encrypt the Secrets Manager secrets.

   ```
   {
       "Version": "2012-10-17",
       "Statement": [
           {
   ```

```
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": [
        "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
        "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
      ]
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": "kms:Decrypt",
      "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
      "Condition": {
        "StringEquals": {
          "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
        }
      }
    }
  ]
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Sid": "",
   "Effect": "Allow",
   "Principal": {
    "Service": "rds.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
  }
 ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=my_identifier
USER_ARN=$(aws sts get-caller-identity --query "Arn" --output text)
```

```
aws iam create-role --role-name my_role_name \
  --assume-role-policy-document '{"Version":"2012-10-17","Statement":
[{"Effect":"Allow","Principal":{"Service":
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'

ROLE_ARN=arn:aws:iam::account_id:role/my_role_name

aws iam put-role-policy --role-name my_role_name \
  --policy-name $PREFIX-secret-reader-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

Creating an RDS Proxy

To manage connections for a DB cluster, create a proxy. You can associate a proxy with an Aurora MySQL or Aurora PostgreSQL DB cluster.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

   For **Proxy configuration**, provide information for the following:

   - **Engine family**. This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For Aurora MySQL, choose **MariaDB and MySQL**. For Aurora PostgreSQL, choose **PostgreSQL**.
   - **Proxy identifier**. Specify a name of that is unique within your AWS account ID and current AWS Region.
   - **Idle client connection timeout**. Choose a time period that a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

     To have the proxy proactively remove stale connections, lower the idle client connection timeout. When the workload is spiking, to save the cost of establishing connections, increase the idle client connection timeout."

   For **Target group configuration**, provide information for the following:

   - **Database**. Choose one Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in Creating an Amazon Aurora DB cluster. Then try creating the proxy again.
   - **Connection pool maximum connections**. Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster,

you can set this value to 100. For details about how RDS Proxy uses this setting, see MaxConnectionsPercent.

- **Session pinning filters**. (Optional) This option allows you to force RDS Proxy to not pin for certain types of detected session states. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

  Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

  The following patterns can be considered safe:

  - `SET` statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
  - You change the session variable value and execute a statement in the same transaction.

  For more information, see Avoiding pinning.
- **Connection borrow timeout**. In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.
- **Initialization query**. (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings, such as time zone and character sets. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`.

For **Authentication**, provide information for the following:

- **IAM role**. Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. Or, you can create a new IAM role from the AWS Management Console.
- **Secrets Manager secrets**. Choose at least one Secrets Manager secret that contains database user credentials that allow the proxy to access the Aurora DB cluster.

- **Client authentication type**. Choose the type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different client authentication type for each secret, then create your proxy by using the AWS CLI or the API instead.
- **IAM authentication**. Choose whether to require or disallow IAM authentication for connections to your proxy. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the AWS CLI or the API instead.

For **Connectivity**, provide information for the following:

- **Require Transport Layer Security**. Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. For an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Subnets**. This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group**. Choose an existing VPC security group. Or, you can create a new security group from the AWS Management Console. You must configure the **Inbound rules** to allow your applications to access the proxy. You must also configure the **Outbound rules** to allow traffic from your DB targets.

  > **Note**
  >
  > This security group must allow connections from the proxy to the database. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
  > When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your

> account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

RDS deploys a proxy over multiple Availability Zones to ensure high availability. To enable cross-AZ communication for such a proxy, the network access control list (ACL) for your proxy subnet must allow engine port specific egress and all ports to ingress. For more information about network ACLs, see Control traffic to subnets using network ACLs. If the network ACL for your proxy and target are identical, you must add a **TCP** protocol ingress rule where the **Source** is set to the VPC CIDR. You must also add an engine port specific **TCP** protocol egress rule where the **Destination** is set to the VPC CIDR.

(Optional) Provide advanced configuration:

- **Enable enhanced logging**. You can enable this setting to troubleshoot proxy compatibility or performance issues.

  When this setting is enabled, RDS Proxy includes detailed information about proxy performance in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. Thus, only enable this setting for debugging and when you have security measures in place to safeguard any sensitive information that appears in the logs.

  To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

AWS CLI

To create a proxy by using the AWS CLI, call the create-db-proxy command with the following required parameters:

- `--db-proxy-name`
- `--engine-family`
- `--role-arn`
- `--auth`

- `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
    --db-proxy-name proxy_name \
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } \
    --auth ProxyAuthenticationConfig_JSON_string \
    --role-arn iam_role \
    --vpc-subnet-ids space_separated_list \
    [--vpc-security-group-ids space_separated_list] \
    [--require-tls | --no-require-tls] \
    [--idle-client-timeout value] \
    [--debug-logging | --no-debug-logging] \
    [--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
    --db-proxy-name proxy_name ^
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
    --auth ProxyAuthenticationConfig_JSON_string ^
    --role-arn iam_role ^
    --vpc-subnet-ids space_separated_list ^
    [--vpc-security-group-ids space_separated_list] ^
    [--require-tls | --no-require-tls] ^
    [--idle-client-timeout value] ^
    [--debug-logging | --no-debug-logging] ^
    [--tags comma_separated_list]
```

The following is an example of the JSON value for the `--auth` option. This example applies a different client authentication type to each secret.

```
[
  {
    "Description": "proxy description 1",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:123456789123:secret/1234abcd-12ab-34cd-56ef-1234567890ab",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
  },

  {
    "Description": "proxy description 2",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122223333:secret/1234abcd-12ab-34cd-56ef-1234567890cd",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_MD5"

  },

  {
    "Description": "proxy description 3",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122221111:secret/1234abcd-12ab-34cd-56ef-1234567890ef",
    "IAMAuth": "REQUIRED"
  }

]
```

> **Tip**
>
> If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see Setting up network prerequisites for examples of how to find them.

> **Note**
>
> The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
> When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one

doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the right associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
    --db-proxy-name value
    [--target-group-name target_group_name]
    [--db-instance-identifiers space_separated_list]  # rds db instances, or
    [--db-cluster-identifiers cluster_id]        # rds db cluster (all instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named default when you create each proxy. You associate an Aurora DB cluster with the target group by calling the function RegisterDBProxyTargets.

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all. Doing so makes it possible to examine their configuration details and choose which ones to modify, delete, and so on.

In order for database applications to use a proxy, you must provide the proxy endpoint in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.

3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy. These include maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

CLI

To view your proxy using the CLI, use the describe-db-proxies command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups  --db-proxy-name proxy_name

aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run describe-db-proxies.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run describe-db-proxy-target-groups `--db-proxy-name`. Use the name of the proxy as the parameter value.
3. To see the details of the Aurora DB cluster associated with the returned target group, run describe-db-proxy-targets.

RDS API

To view your proxies using the RDS API, use the DescribeDBProxies operation. It returns values of the DBProxy data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the DescribeDBProxyTargetGroups operation. It returns values of the DBProxyTargetGroup data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the DescribeDBProxyTargets operation. It returns values of the DBProxyTarget data type.

Connecting to a database through RDS Proxy

You connect to an Aurora DB cluster or cluster that uses Aurora Serverless v2 through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the cluster endpoint. By default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy. You can use that endpoint the same way. For more information, see Overview of proxy endpoints.

Topics

- Connecting to a proxy using native authentication
- Connecting to a proxy using IAM authentication
- Considerations for connecting to a proxy with PostgreSQL

Connecting to a proxy using native authentication

Use the following steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the describe-db-proxies command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].
{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-t3"
        }
    ]
]
```

2. Specify the endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.

3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an Aurora DB cluster. For general information about using IAM, see Security in Amazon Aurora.

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB cluster using IAM authentication.
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

  In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.
- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the `StartupMessage` in PostgreSQL message formats in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`

The startup message can also include the following additional runtime parameters:

- `application_name`

- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`
- `search_path`

For more information about PostgreSQL messaging, see the Frontend/Backend protocol in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC, we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. This prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to *`any/your-application-name`* to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.

For more information, see Avoiding pinning. For more information about connecting using JDBC, see Connecting to the database in the PostgreSQL documentation.

Managing an RDS Proxy

This section provides information on how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

Topics

- Client and database connections
- Configuring connection settings
- Avoiding pinning
- Deleting an RDS Proxy

Modifying an RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

> ⚠ **Important**
>
> The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the AWS CLI or the API instead.

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:

   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
   - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.

- **Client authentication type** – (PostgreSQL only) Change the type of authentication for client connections to the proxy.
- **IAM authentication –** Require or disallow IAM authentication for connections to the proxy.
- **Require Transport Layer Security –** Turn the requirement for Transport layer Security (TLS) on or off.
- **VPC security group** – Add or remove VPC security groups for the proxy to use.
- **Enable enhanced logging –** Enable or disable enhanced logging.

6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:

   - **Database –** Choose a different Aurora cluster.
   - **Connection pool maximum connections –** Adjust what percentage of the maximum available connections the proxy can use.
   - **Session pinning filters –** (Optional) Choose a session pinning filter. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

     Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

  - SET statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
  - You change the session variable value and execute a statement in the same transaction.

For more information, see Avoiding pinning.

- **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
- **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as `SET x=1, y=2`.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands modify-db-proxy, modify-db-proxy-target-group, deregister-db-proxy-targets, and register-db-proxy-targets.

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.

- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy

{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            },
            "TargetGroupName": "default",
            "CreatedDate": "2019-11-30T16:49:27.940Z",
            "DBProxyName": "the-proxy",
            "IsDefault": true
        }
    ]
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name
 default --connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}
```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which Aurora DB clusters the proxy is associated with through its target group. Currently, each proxy can connect to one Aurora DB cluster. The target group tracks the connection details for all the all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-1018"
        },
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "cluster-56-2020-02-25-1399"
        },
        {
            "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-4330"
        }
    ]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,

        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}
```

RDS API

To modify a proxy using the RDS API, you use the operations ModifyDBProxy, ModifyDBProxyTargetGroup, DeregisterDBProxyTargets, and RegisterDBProxyTargets operations.

With `ModifyDBProxy`, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which Aurora cluster the proxy is associated with through its target group. Currently, each proxy can connect to one Aurora cluster. The target group tracks the connection details for the DB instances in an Aurora cluster.

Adding a new database user

In some cases, you might add a new database user to an Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

1. Create a new Secrets Manager secret, using the procedure described in Setting up database credentials in AWS Secrets Manager.
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under **Secrets Manager secrets**.
4. If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

Adding a new database user to a PostgreSQL database

When adding a new user to your PostgreSQL database, if you have run the following command:

```
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the `rdsproxyadmin` user the `CONNECT` privilege so the user can monitor connections on the target database.

```
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing `rdsproxyadmin` to the database user in the command above.

Changing the password for a database user

In some cases, you might change the password for a database user in an Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

Client and database connections

Connections from your application to RDS Proxy are known as client connections. Connections from a proxy to the database are database connections. When using RDS Proxy, client connections terminate at the proxy while database connections are managed within RDS Proxy.

Application-side connection pooling can provide the benefit of reducing recurring connection establishment between your application and RDS Proxy.

Consider the following configuration aspects before implementing an application-side connection pool:

- Client connection max life: RDS Proxy enforces a maximum life of client connections of 24 hours. This value is not configurable. Configure your pool with a maximum connection life less than 24 hours to avoid unexpected client connection drops.
- Client connection idle timeout: RDS Proxy enforces a maximum idle time for client connections. Configure your pool with an idle connection timeout of a value lower than your client connection idle timeout setting for RDS Proxy to avoid unexpected connection drops.

The maximum number of client connections configured in your application-side connection pool does not have to be limited to the **max_connections** setting for RDS Proxy.

Client connection pooling results in a longer client connection life. If your connections experience pinning, then pooling client connections might reduce multiplexing efficiency. Client connections that are pinned but idle in the application-side connection pool continue to hold on to a database connection and prevent the database connection to be reused by other client connections. Review your proxy logs to check whether your connections experience pinning.

> **Note**
>
> RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- IdleClientTimeout
- MaxConnectionsPercent
- MaxIdleConnectionsPercent
- ConnectionBorrowTimeout

IdleClientTimeout

You can specify how long a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, then lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, then raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command modify-db-proxy or the API operation ModifyDBProxy.

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API.

The `MaxConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the Aurora DB cluster used by the target group. The proxy doesn't create all of these connections in advance. This setting allows the proxy to establish these connections as the workload needs them.

For example, for a registered database target with `max_connections` set to 1000, and `MaxConnectionsPercent` set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in the `DatabaseConnectionsBorrowLatency` metric. You can monitor currently used and total allowed database connections by comparing the `DatabaseConnections` and `MaxDatabaseConnectionsAllowed` metrics.

When setting this parameter, note the following best practices:

- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.
- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The `MaxDatabaseConnectionsAllowed` metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the `MaxConnectionsPercent` setting.

  Minimal recommended `MaxConnectionsPercent` values are as follows:

  - db.t3.small: 100
  - db.t3.medium: 55
  - db.t3.large: 35
  - db.r3.large or above: 20

  If multiple target instances are registered with RDS Proxy like an Aurora cluster with reader nodes, set the minimum value based on the smallest registered instance.

To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see AWS Management Console. To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

> ⚠ **Important**
>
> If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's `MaxConnectionsPercent` value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter

aurora_fwd_writer_max_connections_pct. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database.

For information on database connection limits, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. By default, RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

The MaxIdleConnectionsPercent value is expressed as a percentage of the max_connections setting for the RDS DB instance target group. The default value is 50 percent of MaxConnectionsPercent, and the upper limit is the value of MaxConnectionsPercent. For example, if MaxConnectionsPercent, is 80, then the default value of MaxIdleConnectionsPercent is 40.

With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for MaxIdleConnectionsPercent. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the MaxIdleConnectionsPercent setting of DBProxyTargetGroup in the AWS CLI and the API. To learn how to change the value of the MaxIdleConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies when no appropriate database instance is available to handle the request, such as when a failover operation is in process. Using this setting, you can set the best wait period for your application without changing the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus, RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For the lists of tracked statements and variables for Aurora MySQL, see What RDS Proxy tracks for Aurora MySQL databases.

What RDS Proxy tracks for Aurora MySQL databases

Following are the MySQL statements that RDS Proxy tracks:

- DROP DATABASE
- DROP SCHEMA
- USE

Following are the MySQL variables that RDS Proxy tracks:

- `AUTOCOMMIT`
- `AUTO_INCREMENT_INCREMENT`
- `CHARACTER SET (or CHAR SET)`
- `CHARACTER_SET_CLIENT`
- `CHARACTER_SET_DATABASE`
- `CHARACTER_SET_FILESYSTEM`
- `CHARACTER_SET_CONNECTION`
- `CHARACTER_SET_RESULTS`
- `CHARACTER_SET_SERVER`
- `COLLATION_CONNECTION`
- `COLLATION_DATABASE`
- `COLLATION_SERVER`
- `INTERACTIVE_TIMEOUT`
- `NAMES`
- `NET_WRITE_TIMEOUT`
- `QUERY_CACHE_TYPE`
- `SESSION_TRACK_SCHEMA`
- `SQL_MODE`
- `TIME_ZONE`
- `TRANSACTION_ISOLATION (or TX_ISOLATION)`
- `TRANSACTION_READ_ONLY (or TX_READ_ONLY)`

- WAIT_TIMEOUT

Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

  However, for PostgreSQL setting a variable leads to session pinning.
- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see Monitoring RDS Proxy metrics with Amazon CloudWatch.
- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

  For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding `SET` statements from your application code, so that they don't interfere with transaction-level multiplexing.

  For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.

Conditions that cause pinning for Aurora MySQL

For MySQL, the following interactions also cause pinning:

- Explicit table lock statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Creating named locks by using `GET_LOCK` causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, then choose for `SET` operations to not cause pinning. For information about how to do so by setting the session pinning filters property, see [Creating an RDS Proxy]() and [Modifying an RDS Proxy]().
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

  The exact circumstances where these functions cause pinning might differ among Aurora MySQL versions that are compatible with MySQL 5.7.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- RDS Proxy does not pin connections when you use SET LOCAL.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for Aurora PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using `SET` commands.
- Using `PREPARE`, `DISCARD`, `DEALLOCATE`, or `EXECUTE` commands to manage prepared statements.
- Creating temporary sequences, tables, or views.
- Declaring cursors.
- Discarding the session state.
- Listening on a notification channel.
- Loading a library module such as `auto_explain`.
- Manipulating sequences using functions such as `nextval` and `setval`.
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`.

> **Note**
>
> RDS Proxy does not pin on transaction level advisory locks, specifically `pg_advisory_xact_lock`, `pg_advisory_xact_lock_shared`, `pg_try_advisory_xact_lock`, and `pg_try_advisory_xact_lock_shared`.

- Setting a parameter, or resetting a parameter to its default. Specifically, using `SET` and `set_config` commands to assign default values to session variables.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.

Deleting an RDS Proxy

You can delete a proxy when you no longer need it. Or, you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command delete-db-proxy. To remove related associations, also use the deregister-db-proxy-targets command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
    --db-proxy-name proxy_name
    [--target-group-name target_group_name]
    [--target-ids comma_separated_list]       # or
    [--db-instance-identifiers instance_id]       # or
    [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function DeleteDBProxy. To delete related items and associations, you also call the functions DeleteDBProxyTargetGroup and DeregisterDBProxyTargets.

Working with Amazon RDS Proxy endpoints

Learn about endpoints for RDS Proxy and how to use them. By using proxy endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.

- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints. If you aren't familiar with Aurora endpoints, find more information in Amazon Aurora connection management.

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

Tip

When you create a proxy for an Aurora cluster using the AWS Management Console, you can have RDS Proxy automatically create a reader endpoint. For information about the benefits of a reader endpoint, see Using reader endpoints with Aurora clusters.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limitations for proxy endpoints.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

To learn how proxy endpoints work for DB clusters in an Aurora global database, see How RDS Proxy endpoints work with global databases.

Using reader endpoints with Aurora clusters

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Aurora clusters. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

Note

When you specify that a new endpoint is read-only, RDS Proxy requires that the Aurora cluster has one or more reader DB instances. In some cases, you might change the target of the proxy to an Aurora cluster containing only a single writer or a multi-writer Aurora cluster. If you do, any requests to the reader endpoint fail with an error. Requests also fail if the target of the proxy is an RDS instance instead of an Aurora cluster.

If an Aurora cluster has reader instances but those instances aren't available, RDS Proxy waits to send the request instead of returning an error immediately. If no reader instance becomes available within the connection borrow timeout period, the request fails with an error.

How reader endpoints help application availability

In some cases, one or more reader instances in your cluster might become unavailable. If so, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Aurora reader endpoint. RDS Proxy routes connections to only the available reader instances in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader DB instance without any interruption to your application. During the automatic switchover to a new reader instance, RDS Proxy checks the replication lag of the old and new reader instances. RDS Proxy makes sure that the new reader instance is up to date with the same changes as the previous reader instance. That way, your application never sees stale data when RDS Proxy switches from one reader DB instance to another.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same endpoint. RDS Proxy routes the connection to a different reader DB instance that's in `available` state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instances.

If your Aurora cluster doesn't have any available reader instances, RDS Proxy checks whether this condition is temporary or permanent. The behavior in each case is as follows:

- Suppose that your cluster has one or more reader DB instances, but none of them are in the `Available` state. For example, all reader instances might be rebooting or encountering problems. In that case, attempts to connect to a reader endpoint wait for a reader instance to become available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.

- Suppose that your cluster has no reader DB instances. In that case, RDS Proxy returns an error immediately if you try to connect to a reader endpoint. To resolve this problem, add one or more reader instances to your cluster before you connect to the reader endpoint.

How reader endpoints help query scalability

Reader endpoints for a proxy help with Aurora query scalability in the following ways:

- As you add reader instances to your Aurora cluster, RDS Proxy can route new connections to any reader endpoints to the different reader instances. That way, queries performed using one reader endpoint connection don't slow down queries performed using another reader endpoint connection. The queries run on separate DB instances. Each DB instance has its own compute resources, buffer cache, and so on.
- Where practical, RDS Proxy uses the same reader DB instance for all the queries issue using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see Overview of RDS Proxy concepts.
- The more reader DB instances that you have in the cluster, the more simultaneous connections you can make using reader endpoints. For example, suppose that your cluster has four reader DB instances, each configured to support 200 simultaneous connections. Suppose also that your proxy is configured to use 50% of the maximum connections. Here, the maximum number of connections that you can make through the reader endpoints in the proxy is 100 (50% of 200) for reader 1. It's also 100 for reader 2, and so on, for a total of 400. If you double the number of cluster reader DB instances to eight, then the maximum number of connections through the reader endpoints also doubles, to 800.

Examples of using reader endpoints

The following Linux example shows how you can confirm that you're connected to an Aurora MySQL cluster through a reader endpoint. The `innodb_read_only` configuration setting is enabled. Attempts to perform write operations such as `CREATE DATABASE` statements fail with an error. And you can confirm that you're connected to a reader DB instance by checking the DB instance name using the `aurora_server_id` variable.

> **Tip**
>
> Don't rely only on checking the DB instance name to determine whether the connection is read/write or read-only. Remember that DB instances in an Aurora cluster can change roles between writer and reader when failovers happen.

```
$ mysql -h endpoint-demo-reader.endpoint.proxy-demo.us-east-1.rds.amazonaws.com -u
 admin -p
...
mysql> select @@innodb_read_only;
+--------------------+
| @@innodb_read_only |
+--------------------+
|                  1 |
+--------------------+
mysql> create database shouldnt_work;
ERROR 1290 (HY000): The MySQL server is running with the --read-only option so it
 cannot execute this statement

mysql> select @@aurora_server_id;
+---------------------------------------+
| @@aurora_server_id                    |
+---------------------------------------+
| proxy-reader-endpoint-demo-instance-3 |
+---------------------------------------+
```

The following example shows how your connection to a proxy reader endpoint can keep working even when the reader DB instance is deleted. In this example, the Aurora cluster has two reader instances, `instance-5507` and `instance-7448`. The connection to the reader endpoint begins using one of the reader instances. During the example, this reader instance is deleted by a `delete-db-instance` command. RDS Proxy switches to a different reader instance for subsequent queries.

```
$ mysql -h reader-demo.endpoint.proxy-demo.us-east-1.rds.amazonaws.com
  -u my_user -p
```

```
...
mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
+--------------------+
| instance-5507      |
+--------------------+

mysql> select @@innodb_read_only;
+--------------------+
| @@innodb_read_only |
+--------------------+
|                  1 |
+--------------------+

mysql> select count(*) from information_schema.tables;
+----------+
| count(*) |
+----------+
|      328 |
+----------+
```

While the `mysql` session is still running, the following command deletes the reader instance that the reader endpoint is connected to.

```
aws rds delete-db-instance --db-instance-identifier instance-5507 --skip-final-snapshot
```

Queries in the `mysql` session continue working without the need to reconnect. RDS Proxy automatically switches to a different reader DB instance.

```
mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
+--------------------+
| instance-7448      |
+--------------------+

mysql> select count(*) from information_schema.TABLES;
+----------+
| count(*) |
+----------+
|      328 |
+----------+
```

Accessing Aurora databases across VPCs

By default, the components of your Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora DB cluster in one VPC from resources in another VPC, such as EC2 instances. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. The proxy itself resides in the same VPC as the Aurora DB cluster. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora work. Each VPC should have its own associated network resources such as an internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon Aurora for the steps to set up another VPC to use Aurora successfully. You can also examine your existing VPC in the Amazon EC2 console to see the kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster that you want to connect to. Follow the procedure in Creating an RDS Proxy.
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in Creating a proxy endpoint.
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Aurora DB cluster, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster, make new selections. Make these based on the subnets and security groups from the VPC that you chose.

7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
8. Wait for the new endpoint to reach the **Available** state.
9. Make a note of the full endpoint name. This is the value ending in *`Region_name`*`.rds.amazonaws.com` that you supply as part of the connection string for your database application.
10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then, log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

   The details page for that proxy appears.
4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

   The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

   Connections that use read/write endpoints can perform any kind of operations, such as data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources that normally use to access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see Accessing Aurora databases across VPCs.
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint to only a portion of the VPC's address range being able to connect to it, remove one or more subnets.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, then keep the default choice.

   If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console later.
10. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI create-db-proxy-endpoint command.

Include the following required parameters:

- `--db-proxy-name` *`value`*
- `--db-proxy-endpoint-name` *`value`*
- `--vpc-subnet-ids` *`list_of_ids`*. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value affects only Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Aurora clusters, see Using reader endpoints with Aurora clusters .
- `--vpc-security-group-ids` *`value`*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
  --db-proxy-name my-proxy \
  --db-proxy-endpoint-name my-endpoint \
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \
  --target-role READ_ONLY \
  --vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API CreateDBProxyEndpoint action.

Viewing proxy endpoints

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:

   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more proxy endpoints, use the AWS CLI describe-db-proxy-endpoints command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API DescribeDBProxyEndpoints operation.

Modifying a proxy endpoint

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or, on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a proxy endpoint, use the AWS CLI modify-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint \
  --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint ^
  --new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API ModifyDBProxyEndpoint operation.

Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

> **Note**
>
> You can't delete the default proxy endpoint that RDS Proxy automatically creates for each proxy.
> When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.

4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or, on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the delete-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the DeleteDBProxyEndpoint operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Limitations for proxy endpoints

RDS Proxy endpoints have the following limitations:

- Each proxy has a default endpoint that you can modify but not create or delete.
- The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.
- When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

- Reader endpoints aren't available for Aurora multi-writer clusters.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see Using Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

> **Note**
>
> RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.
> Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for the default endpoint of a proxy that performs read/write requests.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName`, `EndpointName`
- Dimension set 3: `ProxyName`, `TargetGroup`, `Target`

- Dimension set 4: `ProxyName`, `TargetGroup`, `TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
`AvailabilityPercentage`	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is `Average`.	1 minute	Dimension set 4
`ClientConnections`	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is `Sum`.	1 minute	Dimension set 1, Dimension set 2
`ClientConnectionsClosed`	The number of client connections closed. The most useful statistic for this metric is `Sum`.	1 minute and above	Dimension set 1, Dimension set 2
`ClientConnectionsNoTLS`	The current number of client connections without Transport Layer Security (TLS). This metric is reported every	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
	minute. The most useful statistic for this metric is Sum.		
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsSetupFailedAuth	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsSetupSucceeded	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
`DatabaseConnectionRequests`	The number of requests to create a database connection. The most useful statistic for this metric is `Sum`.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
`DatabaseConnectionRequestsWithTLS`	The number of requests to create a database connection with TLS. The most useful statistic for this metric is `Sum`.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
`DatabaseConnections`	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is `Sum`.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
`DatabaseConnectionsBorrowLatency`	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is `Average`.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsCurrentlyBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsCurrentlyInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsCurrentlySessionPinned	The current number of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
`DatabaseConnectionsSetupFailed`	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
`DatabaseConnectionsSetupSucceeded`	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
`DatabaseConnectionsWithTLS`	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
`MaxDatabaseConnectionsAllowed`	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2, Dimension set 3, Dimension set 4
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
`QueryRequestsTLS`	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is `Sum`.	1 minute and above	Dimension set 1, Dimension set 2
`QueryResponseLatency`	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is `Average`.	1 minute and above	Dimension set 1, Dimension set 2

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

⚠ **Important**

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.
In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

Working with RDS Proxy events

An *event* indicates a change in an environment such as an AWS environment or a service or application from a software as a service (SaaS) partner. Or, it can be one of your own custom applications or services. For example, Amazon Aurora generates an event when you create or modify an RDS Proxy. Amazon Aurora delivers events to Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events.
- To learn how to configure Amazon Aurora to send events to EventBridge, see Creating a rule that triggers on an Amazon Aurora event.

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0204	RDS modified DB proxy *name*.	
configuration change	RDS-EVENT-0207	RDS modified the end point of the DB proxy *name*.	
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy *name*.	
configuration change	RDS-EVENT-0213	RDS detected creation of DB instance *name* and	

Category	RDS event ID	Message	Notes
		automatically added it to target group *name* of DB proxy *name*.	
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance *name* and automatically removed it from target group *name* of DB proxy *name*.	
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster *name* and automatically removed it from target group *name* of DB proxy *name*.	
creation	RDS-EVENT-0203	RDS created DB proxy *name*.	
creation	RDS-EVENT-0206	RDS created endpoint *name* for DB proxy *name*.	
deletion	RDS-EVENT-0205	RDS deleted DB proxy *name*.	
deletion	RDS-EVENT-0208	RDS deleted endpoint *name* for DB proxy *name*.	

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy *name* because there aren't enough IP addresses available in your subnets: *name*. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommended in the RDS Proxy documentation.	To determine the recommended number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

Examples

- Preserving Connections to a MySQL Database Across a Failover
- Adjusting the max_connections Setting for an Aurora DB Cluster

Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...

mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
+--------------------+
| instance-9814       |
+---------------------+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                 mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com
 -u admin_user -p
$ # Initially, instance-9814 is the writer.
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us.us-east-1.rds.amazonaws.com -u admin_user -p

Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the `max_connections` setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.7. You specify a value for the `max_connections` setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-57-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-57

aws rds create-db-parameter-group --region $REGION \
  --db-parameter-group-family aurora-mysql5.7 \
  --db-parameter-group-name $CLUSTER_PARAM_GROUP \
  --description "Aurora MySQL 5.7 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep "^max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-
group-name $CLUSTER_PARAM_GROUP \
  --parameters "ParameterName=max_connections,ParameterValue=$
$answer,ApplyMethod=immediate"
```

```
echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep "^max_connections"
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

Topics

Verifying connectivity for a proxy

You can use the following commands to verify that all components such as the proxy, database, and compute instances in the connection can communicate with the each other.

Examine the proxy itself using the describe-db-proxies command. Also examine the associated target group using the describe-db-proxy-target-groups command. Check that the details of the targets match the Aurora cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the describe-db-proxy-targets command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the describe-db-proxy-targets command includes a TargetHealth field. You can examine the fields State, Reason, and Description inside TargetHealth to check if the proxy can communicate with the underlying DB instance.

- A State value of AVAILABLE indicates that the proxy can connect to the DB instance.
- A State value of UNAVAILABLE indicates a temporary or permanent connection problem. In this case, examine the Reason and Description fields. For example, if Reason has a value of PENDING_PROXY_CAPACITY, try connecting again after the proxy finishes its scaling operation. If Reason has a value of UNREACHABLE, CONNECTION_FAILED, or AUTH_FAILURE, use the explanation from the Description field to help you diagnose the issue.
- The State field might have a value of REGISTERING for a brief time before changing to AVAILABLE or UNAVAILABLE.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306

nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance Aurora cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the SecretString field displayed by get-secret-value is encoded as a JSON string that includes the username and password fields. The following example shows the format of the SecretString field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

Common issues and solutions

This section describes some common issues and potential solutions when using RDS Proxy.

After running the `aws rds describe-db-proxy-targets` CLI command, if the `TargetHealth` description states `Proxy does not have any registered credentials`, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the Secrets Manager secret used by the proxy is valid.

You might encounter the following RDS events while creating or connecting to a DB proxy.

Category	RDS event ID	Description
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommend ed number for your instance class, see Planning for IP address capacity.

Category	RDS event ID	Description
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
`403: The security token included in the request is invalid`	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
`ERROR 1040 (HY000): Connections rate limit exceeded (`*`limit_value`*` )`	The rate of connection requests from the client to the proxy has exceeded the limit.
`ERROR 1040 (HY000): IAM authentication rate limit exceeded`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.

Error	Causes or workarounds
ERROR 1040 (HY000): Number simultaneous connections exceeded (*limit_value*)	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user '*DB_USER*'@'%' (usi password: YES)	The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
ERROR 1105 (HY000): Unknown error	An unknown error occurred.
ERROR 1231 (42000): Variable ''character_set_client'' can't be set to the value of *value*	The value set for the `character_set_client` parameter is not valid. For example, the value `ucs2` is not valid because it can crash the MySQL server.
ERROR 3159 (HY000): This RDS Proxy requires TLS connections.	You enabled the setting **Require Transport Layer Security** in the proxy but your connection included the parameter `ssl-mode=DISABLED` in the MySQL client. Do either of the following: • Disable the setting **Require Transport Layer Security** for the proxy. • Connect to the database using the minimum setting of `ssl-mode=REQUIRED` in the MySQL client.

Error	Causes or workarounds
`ERROR 2026 (HY000): SSL connection error: Internal Server Error`	The TLS handshake to the proxy failed. Some possible reasons include the following: - SSL is required but the server doesn't support it. - An internal server error occurred. - A bad handshake occurred.
`ERROR 9501 (HY000): Timed-out waiting to acquire database connection`	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: - The proxy is unable to establish a database connection because the maximum connections have been reached - The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
`IAM authentication is allowed only with SSL connections.`	The user tried to connect to the database using IAM authentication with the setting `sslmode=disable` in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of `sslmode=require` in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.
`This RDS Proxy requires TLS connections.`	The user enabled the option **Require Transport Layer Security** but tried to connect with `sslmode=disable` in the PostgreSQL client.	To fix this error, do one of the following: - Disable the proxy's **Require Transport Layer Security** option.

Error	Cause	Solution
		- Connect to the database using the minimum setting of `sslmode=allow` in the PostgreSQL client.
`IAM authentication failed for user` *`user_name`* `. Check the IAM token for this user and try again.`	This error might be due to the following reasons: - The client supplied the incorrect IAM user name. - The client supplied an incorrect IAM authorization token for the user. - The client is using an IAM policy that does not have the necessary permissions. - The client supplied an expired IAM authorization token for the user.	To fix this error, do the following: 1. Confirm that the provided IAM user exists. 2. Confirm that the IAM authorization token belongs to the provided IAM user. 3. Confirm that the IAM policy has adequate permissions for RDS. 4. Check the validity of the IAM authorization token used.
`This RDS proxy has no credentials for the role` *`role_name`* `. Check the credentials for this role and try again.`	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role. For more information, see Setting up AWS Identity and Access Management (IAM) policies.
`RDS supports only IAM, MD5, or SCRAM authentication.`	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy.	If you're not using IAM authentication, use the MD5 or SCRAM password authentic ation.

Error	Cause	Solution
`A user name is missing from the connection startup packet. Provide a user name for this connection.`	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
`Feature not supported : RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.`	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL `psql` CLI, use a version greater than or equal to 7.4.
`Feature not supported : RDS Proxy currently doesn't support streaming replication mode.`	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
`Feature not supported : RDS Proxy currently doesn't support the option` *`option_name`* `.`	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
`The IAM authentication failed because of too many competing requests.`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.

Error	Cause	Solution
`The maximum number of client connections to the proxy exceeded` *number_value* `.`	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
`Rate of connection to proxy exceeded` *number_value* `.`	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.
`The password that was provided for the role` *role_name* `is wrong.`	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
`The IAM authentication failed for the role` *role_name* `. Check the IAM token for this role and try again.`	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
`IAM is allowed only with SSL connections.`	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.
`Unknown error.`	An unknown error occurred.	Reach out to AWS Support to investigate the issue.

Error	Cause	Solution
`Timed-out waiting to acquire database connection.`	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following : - The proxy can't establish a database connection because the maximum connections have been reached. - The proxy can't establish a database connection because the database is unavailable.	Possible solutions are the following: - Check the target of the RDS DB instance Aurora cluster status to see if it's unavailable. - Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.
`Request returned an error: ` *`database_error`* `.`	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: `Request returned an error: database "your-database-name" does not exist`. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. This helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
 DBProxy:
   Type: AWS::RDS::DBProxy
   Properties:
     DBProxyName: CanaryProxy
     EngineFamily: MYSQL
     RoleArn:
      Fn::ImportValue: SecretReaderRoleArn
     Auth:
       - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
     VpcSubnetIds:
       Fn::Split: [",", "Fn::ImportValue": SubnetIds]

 ProxyTargetGroup:
   Type: AWS::RDS::DBProxyTargetGroup
   Properties:
     DBProxyName: CanaryProxy
     TargetGroupName: default
     DBInstanceIdentifiers:
       - Fn::ImportValue: DBInstanceName
   DependsOn: DBProxy
```

For more information about the resources in this sample, see `DBProxy` and `DBProxyTargetGroup`.

For more information about resources that you can create using AWS CloudFormation, see RDS resource type reference.

Using RDS Proxy with Aurora global databases

An *Aurora global database* is a single database that spans multiple AWS Regions, allowing for low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single AWS Region, but upon multiple Regions and different Availability Zones. For more information, see Using Amazon Aurora global databases.

You can use RDS Proxy with any DB cluster in an Aurora global database. Before you begin to use these features together, make sure that you familiarize yourself with the following information.

> ⚠ **Important**
>
> If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's `MaxConnectionsPercent` value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter `aurora_fwd_writer_max_connections_pct`. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database.

Limitations for RDS Proxy with global databases

When the Aurora DB cluster has write forwarding turned on, RDS Proxy doesn't support the `SESSION` value for the `aurora_replica_read_consistency` variable. Setting this value can cause unexpected behavior.

How RDS Proxy endpoints work with global databases

When you understand how RDS Proxy endpoints work with global databases, you can better manage your applications that use Aurora databases with both of these features.

For a proxy with a global database's primary cluster as the registered target, the proxy endpoints work the same way as with any Aurora DB cluster. The proxy's read/write endpoints send all requests to the writer instance of the cluster. The proxy's read-only endpoints send all requests to the reader instances. If a reader becomes unavailable while a connection is open, RDS Proxy redirects subsequent queries on the connection to another reader instance. For a proxy with a secondary cluster as the registered target, requests that are sent to the proxy's read-only endpoints are also sent to the reader instances. Because the cluster has no writer instances, requests that are sent to read/write endpoints fail with the error "`The target group doesn't have any associated read/write instances`".

Global database switchover and failover operations both involve a role switch between the primary and one of the secondary DB clusters. When the selected secondary cluster becomes the new primary, one of its reader instances is promoted to a writer. This DB instance is now the new writer instance for the global cluster. Make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint.

RDS Proxy queues all requests through read/write endpoints and sends them to the writer instance of the new primary cluster as soon as it's available. It does so regardless of whether the switchover or failover operation has completed. During switchover or failover, the default endpoint of the proxy for the old primary cluster still accepts write operations. However, as soon as that cluster becomes a secondary cluster, all of the write operations fail. To learn how and when to perform specific global switchover or failover tasks, see the following topics:

- Global database switchover – Performing switchovers for Amazon Aurora global databases
- Global database failover – Recovering an Amazon Aurora global database from an unplanned outage

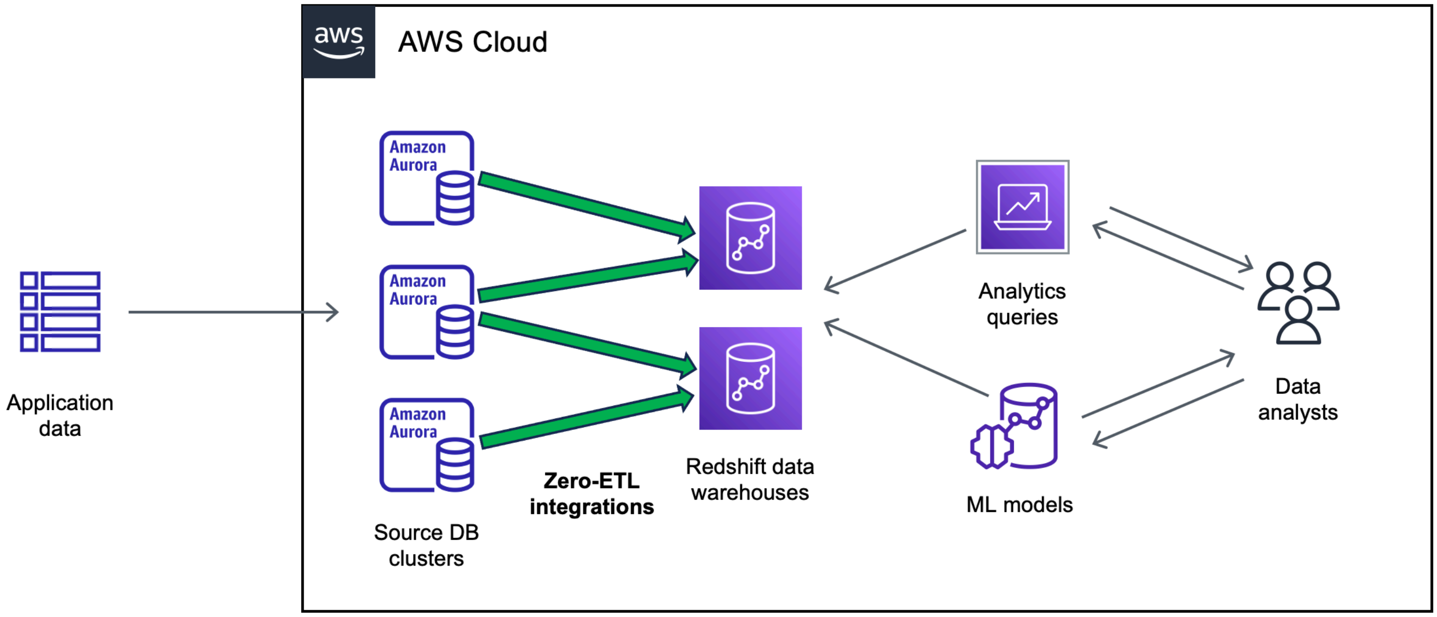
Working with Aurora zero-ETL integrations with Amazon Redshift

An Aurora zero-ETL integration with Amazon Redshift enables near real-time analytics and machine learning (ML) using Amazon Redshift on petabytes of transactional data from Aurora. It's a fully managed solution for making transactional data available in Amazon Redshift after it is written to an Aurora DB cluster. *Extract, transform,* and *load* (ETL) is the process of combining data from multiple sources into a large, central data warehouse.

A zero-ETL integration makes the data in your Aurora DB cluster available in Amazon Redshift in near real-time. Once that data is in Amazon Redshift, you can power your analytics, ML, and AI workloads using the built-in capabilities of Amazon Redshift, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker, Amazon QuickSight, and other AWS services.

To create a zero-ETL integration, you specify an Aurora DB cluster as the *source*, and an Amazon Redshift data warehouse as the *target*. The integration replicates data from the source database into the target data warehouse.

The following diagram illustrates this functionality:



The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple Aurora DB clusters into a single Amazon Redshift namespace, enabling you to derive insights across multiple applications.

For information about pricing for zero-ETL integrations, see Amazon Aurora pricing and Amazon Redshift pricing.

Topics

Benefits

Aurora zero-ETL integrations with Amazon Redshift have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage Amazon Redshift's analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an Aurora DB cluster to an Amazon Redshift data warehouse.

Source DB cluster

The Aurora DB cluster where data is replicated from. For Aurora MySQL, you can specify a DB cluster that uses provisioned DB instances or Aurora Serverless v2 DB instances as the source. For the Aurora PostgreSQL preview, you can only specify a cluster that uses provisioned DB instances.

Target data warehouse

The Amazon Redshift data warehouse where the data is replicated to. There are two types of data warehouse: a provisioned cluster data warehouse and a serverless data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a *cluster*. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an Amazon Redshift engine and contain one or more databases.

Multiple source DB clusters can write to the same target.

For more information, see Data warehouse system architecture in the *Amazon Redshift Developer Guide*.

Limitations

The following limitations apply to Aurora zero-ETL integrations with Amazon Redshift.

Topics

General limitations

- The source DB cluster must be in the same Region as the target Amazon Redshift data warehouse.
- You can't rename a DB cluster or any of its instances if it has existing integrations.
- You can't delete a DB cluster that has existing integrations. You must delete all associated integrations first.
- If you stop the source DB cluster, the last few transactions might not be replicated to the target data warehouse until you resume the cluster.
- If your cluster is the source of a blue/green deployment, the blue and green environments can't have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.
- A DB cluster must contain at least one DB instance in order to be the source of an integration.
- If your source cluster is the primary DB cluster in an Aurora global database and it fails over to one of its secondary clusters, the integration becomes inactive. You must delete and recreate the integration.
- You can't create an integration for a source database that has another integration being actively created.
- When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag.
- Some data types aren't supported. For more information, see the section called "Data type differences".
- Foreign key references with predefined table updates aren't supported. Specifically, `ON DELETE` and `ON UPDATE` rules aren't supported with `CASCADE`, `SET NULL`, and `SET DEFAULT` actions. Attempting to create or update a table with such references to another table will put the table into a failed state.
- `ALTER TABLE` partition operations cause your table to resynchronize in order to reload data from Aurora to Amazon Redshift. The table will be unavailable for querying while it's resynchronizing. For more information, see the section called "One or more of my Amazon Redshift tables requires a resync".
- XA transaction aren't supported.
- Object identifiers (including database name, table name, column names, and others) can contain only alphanumeric characters, numbers, $, and _ (underscore).

Aurora MySQL limitations

- Your source DB cluster must be running Aurora MySQL version 3.05 (compatible with MySQL 8.0.32) or higher.
- Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. Don't use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.
- Aurora MySQL system tables, temporary tables, and views aren't replicated to Amazon Redshift.
- Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.

Aurora PostgreSQL preview limitations

> ⚠ **Important**
>
> The zero-ETL integrations with Amazon Redshift feature for Aurora PostgreSQL is in preview release. The documentation and the feature are both subject to change. You can use this feature only in test environments, not in production environments. For preview terms and conditions, see *Betas and Previews* in AWS Service Terms.

- Your source DB cluster must be running **Aurora PostgreSQL (compatible with PostgreSQL 15.4 and Zero-ETL Support)**.
- You can create and manage zero-ETL integrations for Aurora PostgreSQL only in the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-east-2) AWS Region. You can use the preview environment to test beta, release candidate, and early production versions of PostgreSQL database engine software.
- You can create and manage integrations for Aurora PostgreSQL only using the AWS Management Console. You can't use the AWS Command Line Interface (AWS CLI), the Amazon RDS API, or any of the AWS SDKs.
- When you create a source DB cluster, the parameter group that you choose must already have the required DB cluster parameter values configured. You can't create a new parameter group afterwards and then associate it with the cluster. For a list of required parameters, see the section called "Step 1: Create a custom DB cluster parameter group".

- You can't modify an integration after you create it. If you need to change certain settings, you must delete and recreate the integration.
- Currently, Aurora PostgreSQL DB clusters that are the source of an integration don't perform garbage collection of logical replication data.
- All databases created within the source Aurora PostgreSQL DB cluster must use UTF-8 encoding.
- Column names can't contain any of the following characters: commas (,), semicolons (;), parentheses ( ), curly brackets { }, newlines (\n), tabs (\t), equal signs (=), and spaces.
- Zero-ETL integrations with Aurora PostgreSQL don't support the following:
  - Aurora Serverless v2 DB instances. Your source DB cluster must use provisioned DB instances.
  - Custom data types or data types created by extensions.
  - [Subtransactions](#) on the source DB cluster.
  - Renaming of schemas or databases within a source DB cluster.
  - Restoring from a DB cluster snapshot or using Aurora cloning to create a source DB cluster. If you want to bring existing data into a preview cluster, then you must use the `pg_dump` or `pg_restore` utilities.
  - Creation of logical replication slots on the writer instance of the source DB cluster.
  - Large field values that require The Oversized-Attribute Storage Technique (TOAST).
  - `ALTER TABLE` partition operations. These operations can cause your table to resynchronize and eventually enter a `Failed` state. If a table fails, then you must drop and recreate it.

Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see Considerations in the *Amazon Redshift Management Guide*.

Quotas

Your account has the following quotas related to Aurora zero-ETL integrations with Amazon Redshift. Each quota is per-Region unless otherwise specified.

Name	Default	Description
Integrations	100	The total number of integrations within an AWS account.

Name	Default	Description
Integrations per target data warehouse	50	The number of integrations sending data to a single target Amazon Redshift data warehouse.
Integrations per source cluster	5 for Aurora MySQL, 1 for Aurora PostgreSQL	The number of integrations sending data from a single source DB cluster.

In addition, Amazon Redshift places certain limits on the number of tables allowed in each DB instance or cluster node. For more information, see Quotas and limits in Amazon Redshift in the *Amazon Redshift Management Guide*.

Supported Regions

Aurora zero-ETL integrations with Amazon Redshift are available in a subset of AWS Regions. For a list of supported Regions, see the section called “Zero-ETL integrations ”.

Getting started with Aurora zero-ETL integrations with Amazon Redshift

Before you create a zero-ETL integration with Amazon Redshift, configure your Aurora DB cluster and your Amazon Redshift data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. Create a custom DB cluster parameter group.
2. Create a source DB cluster.
3. Create a target Amazon Redshift data warehouse.

After you complete these tasks, continue to the section called “Creating zero-ETL integrations”.

You can use the AWS SDKs to automate the setup process for you. For more information, see the section called “Set up an integration using the AWS SDKs (Aurora MySQL only)”.

Step 1: Create a custom DB cluster parameter group

Aurora zero-ETL integrations with Amazon Redshift require specific values for the DB cluster parameters that control replication. Specifically, Aurora MySQL requires *enhanced binlog* (`aurora_enhanced_binlog`), and Aurora PostgreSQL requires *enhanced logical replication* (`aurora.enhanced_logical_replication`).

To configure binary logging or logical replication, you must first create a custom DB cluster parameter group, and then associate it with the source DB cluster.

Create a custom DB cluster parameter group with the following settings depending on your source DB engine. For instructions to create a parameter group, see the section called “Working with DB cluster parameter groups”.

Aurora MySQL (aurora-mysql8.0 family):

- `aurora_enhanced_binlog=1`
- `binlog_backup=0`
- `binlog_format=ROW`
- `binlog_replication_globaldb=0`
- `binlog_row_image=full`
- `binlog_row_metadata=full`

In addition, make sure that the `binlog_transaction_compression` parameter is *not* set to `ON`, and that the `binlog_row_value_options` parameter is *not* set to `PARTIAL_JSON`.

For more information about Aurora MySQL enhanced binlog, see the section called “Setting up enhanced binlog”.

Aurora PostgreSQL (aurora-postgresql15 family):

> **Note**
>
> For Aurora PostgreSQL DB clusters, you must create the custom parameter group within the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-east-2) AWS Region.

- `rds.logical_replication=1`
- `aurora.enhanced_logical_replication=1`
- `aurora.logical_replication_backup=0`
- `aurora.logical_replication_globaldb=0`

Enabling enhanced logical replication (`aurora.enhanced_logical_replication`) automatically sets the `REPLICA IDENTITY` parameter to `FULL`, which means that all column values are written to the write ahead log (WAL). This will increase the IOPS for your source DB cluster.

Step 2: Select or create a source DB cluster

After you create a custom DB cluster parameter group, choose or create an Aurora MySQL or Aurora PostgreSQL DB cluster. This cluster will be the source of data replication to Amazon Redshift.

The cluster must be running Aurora MySQL version 3.05 (compatible with MySQL 8.0.32) or higher, or Aurora PostgreSQL (compatible with PostgreSQL 15.4 and Zero-ETL Support). For instructions to create a DB cluster, see the section called "Creating a DB cluster".

> **Note**
>
> You must create Aurora PostgreSQL DB clusters within the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-east-2) AWS Region.

Under **Additional configuration**, change the default **DB cluster parameter group** to the custom parameter group that you created in the previous step.

> **Note**
>
> For Aurora MySQL, if you associate the parameter group with the DB cluster *after* the cluster is already created, you must reboot the primary DB instance in the cluster to apply the changes before you can create a zero-ETL integration. For instructions, see the section called "Rebooting an Aurora DB cluster or instance".
> During the preview release of Aurora PostgreSQL zero-ETL integrations with Amazon Redshift, you must associate the cluster with the custom DB cluster parameter group *while*

creating the cluster. You can't perform this action after the source DB cluster is already created, otherwise you need to delete and recreate the cluster.

Step 3: Create a target Amazon Redshift data warehouse

After you create your source DB cluster, you must create and configure a target data warehouse in Amazon Redshift. The data warehouse must meet the following requirements:

- Created in *preview* (for Aurora PostgreSQL sources only). For Aurora MySQL sources, you must create production clusters and workgroups.
  - To create a provisioned cluster in preview, choose **Create preview cluster** from the banner on the provisioned clusters dashboard. For more information, see Creating a preview cluster.

    
    Try new Amazon Redshift features in preview.
    Create a cluster with preview features. Production use of the cluster is not supported. Use this cluster for testing only.

    When creating the cluster, set the **Preview track** to `preview_2023`.
  - To create a Redshift Serverless workgroup in preview, choose **Create preview workgroup** from the banner on the Serverless dashboard. For more information, see Creating a preview workgroup.

    
    Try new Amazon Redshift features in preview
    Create a workgroup with preview features. Production use of the workgroup is not supported. Use this workgroup for testing only.

- Using an RA3 node type (`ra3.xlplus`, `ra3.4xlarge`, or `ra3.16xlarge`) , or Redshift Serverless.
- Encrypted (if using a provisioned cluster). For more information, see Amazon Redshift database encryption.

For instructions to create a data warehouse, see Creating a cluster for provisioned clusters, or Creating a workgroup with a namespace for Redshift Serverless.

Enable case sensitivity on the data warehouse

For the integration to be successful, the case sensitivity parameter (`enable_case_sensitive_identifier`) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.

To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see Managing parameter groups using the console or Configuring parameter values using the AWS CLI.

  > **Note**
  >
  > Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the AWS CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Send the following update-workgroup request:

  ```
  aws redshift-serverless update-workgroup \
    --workgroup-name target-workgroup \
    --config-parameters
   parameterKey=enable_case_sensitive_identifier,parameterValue=true
  ```

  You don't need to reboot a workgroup after you modify its parameter values.

Configure authorization for the data warehouse

After you create a data warehouse, you must configure the source Aurora DB cluster as an authorized integration source. For instructions, see Configure authorization for your Amazon Redshift data warehouse.

Set up an integration using the AWS SDKs (Aurora MySQL only)

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the AWS SDK for Python (Boto3) to create a source Aurora MySQL DB cluster and target Amazon Redshift data warehouse, each with the required parameter values. It then waits for the clusters to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip install time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

Python code example

```
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default Region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_cluster_name = 'my-source-cluster' # A name for the source cluster
source_param_group_name = 'my-source-param-group' # A name for the source parameter
 group
target_cluster_name = 'my-target-cluster' # A name for the target cluster
target_param_group_name = 'my-target-param-group' # A name for the target parameter
 group

def create_source_cluster(*args):
    """Creates a source Aurora MySQL DB cluster"""

    response = rds.create_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='aurora-mysql8.0',
        Description='For Aurora MySQL zero-ETL integrations'
    )
    print('Created source parameter group: ' + response['DBClusterParameterGroup']
['DBClusterParameterGroupName'])
```

```
    response = rds.modify_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        Parameters=[
            {
                'ParameterName': 'aurora_enhanced_binlog',
                'ParameterValue': '1',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_backup',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_format',
                'ParameterValue': 'ROW',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_replication_globaldb',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_image',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_metadata',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            }
        ]
    )
    print('Modified source parameter group: ' +
 response['DBClusterParameterGroupName'])

    response = rds.create_db_cluster(
        DBClusterIdentifier=source_cluster_name,
        DBClusterParameterGroupName=source_param_group_name,
        Engine='aurora-mysql',
        EngineVersion='8.0.mysql_aurora.3.05.2',
        DatabaseName='myauroradb',
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source cluster: ' + response['DBCluster']['DBClusterIdentifier'])
    source_arn = (response['DBCluster']['DBClusterArn'])
    create_target_cluster(target_cluster_name, source_arn, target_param_group_name)

    response = rds.create_db_instance(
        DBInstanceClass='db.r6g.2xlarge',
        DBClusterIdentifier=source_cluster_name,
        DBInstanceIdentifier=source_cluster_name + '-instance',
        Engine='aurora-mysql'
    )
    return(response)

    )
    target_status = response['Clusters'][0]['ClusterStatus']
    target_arn = response['Clusters'][0]['ClusterNamespaceArn']

    # Every 60 seconds, check whether the clusters are available.
    if source_status != 'available' or target_status != 'available' or
 source_instance_status != 'available':
        time.sleep(60)
        response = wait_for_cluster_availability(
            source_cluster_name, target_cluster_name)
    else:
        print('Clusters available. Ready to create zero-ETL integration.')
        create_integration(source_arn, target_arn)
        return

def create_integration(source_arn, target_arn):
    """Creates a zero-ETL integration using the source and target clusters"""

    response = rds.create_integration(
        SourceArn=source_arn,
        TargetArn=target_arn,
        IntegrationName='my-integration'
    )
    print('Creating integration: ' + response['IntegrationName'])

def main():
    """main function"""
    create_source_cluster(source_cluster_name, source_param_group_name)
    wait_for_cluster_availability(source_cluster_name, target_cluster_name)
```

```
if __name__ == "__main__":
    main()
```

Next steps

With a source Aurora DB cluster and an Amazon Redshift target data warehouse, you can now create a zero-ETL integration and replicate data. For instructions, see the section called “Creating zero-ETL integrations”.

Creating Aurora zero-ETL integrations with Amazon Redshift

When you create an Aurora zero-ETL integration, you specify the source Aurora DB cluster and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured Amazon Redshift target.

Topics

Prerequisites

Before you create a zero-ETL integration, you must create a source DB cluster and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see the section called “Getting started with zero-ETL integrations”.

Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse. You don't need this permission if the same account owns the Amazon Redshift data warehouse and this account is an authorized principal for that data warehouse. For information about adding authorized principals, see Configure authorization for your Amazon Redshift data warehouse.

The following sample policy demonstrates the least privilege permissions required to create and manage integrations. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

Note

Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (`/`) rather than a colon (`:`) before the serverless namespace UUID.

- Provisioned cluster – arn:aws:**redshift**:{region}:{account-id}:namespace**:***namespace-uuid*
- Serverless – arn:aws:**redshift-serverless**:{region}:{account-id}:namespace**/***namespace-uuid*

Sample policy

Important

For the Aurora PostgreSQL preview, all ARNs and actions within the Amazon RDS Database Preview Environment have `-preview` appended to the service namespace. For example, rds-*preview*:CreateIntegration and arn:aws:rds-*preview*:....

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "rds:CreateIntegration"
        ],
        "Resource": [
            "arn:aws:rds:{region}:{account-id}:cluster:source-db",
            "arn:aws:rds:{region}:{account-id}:integration:*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "rds:DescribeIntegrations"
        ],
        "Resource": ["*"]
    },
    {
        "Effect": "Allow",
        "Action": [
            "rds:DeleteIntegration",
            "rds:ModifyIntegration"
        ],
        "Resource": [
            "arn:aws:rds:{region}:{account-id}:integration:*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "redshift:CreateInboundIntegration"
        ],
        "Resource": [
            "arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid"
        ]
    }]
}
```

Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another AWS account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another AWS account that you own.

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

Required permissions and trust policy

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "redshift:DescribeClusters",
            "redshift-serverless:ListNamespaces"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "AWS": "arn:aws:iam::{external-account-id}:root"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations

You can create an Aurora MySQL zero-ETL integration using the AWS Management Console, the AWS CLI, or the RDS API. To create an Aurora PostgreSQL integration, you must use the AWS Management Console.

RDS console

To create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   If you're using an Aurora PostgreSQL DB cluster as the source of the integration, you must sign in to the Amazon RDS Database Preview Environment at https://us-east-2.console.aws.amazon.com/rds-preview/home?region=us-east-2#databases.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from. The cluster must be running Aurora MySQL version 3.05 or higher, or Aurora PostgreSQL (compatible with PostgreSQL 15.4 and Zero-ETL Support).

   > **Note**
   >
   > For MySQL sources, RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see [the section called "Step 1: Create a custom DB cluster parameter group"](#).
   > Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.
7. If you selected an Aurora PostgreSQL source cluster, under **Named database**, specify the named database to use as the source for your integration. The PostgreSQL resource model allows the creation of multiple databases within a single DB cluster, but only one can be used for each zero-ETL integration.

   The named database must be created from `template1`. For more information, see [Template Databases](#) in the PostgreSQL documentation.

8. (Optional) If you selected an Aurora MySQL source DB cluster, select **Customize data filtering options** and add data filters to your integration. You can use data filters to define the scope of replication to the target data warehouse. For more information, see the section called "Data filtering for zero-ETL integrations".
9. Once your source DB cluster is successfully configured, choose **Next**.
10. For **Target**, do the following:

    1. (Optional) To use a different AWS account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data warehouses. For instructions to create the IAM role, see the section called "Choosing a target data warehouse in a different account".
    2. For **Amazon Redshift data warehouse**, select the target for replicated data from the source DB cluster. You can choose a provisioned Amazon Redshift *cluster* or a Redshift Serverless *namespace* as the target.

    > **Note**
    >
    > RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see Turn on case sensitivity for your data warehouse and Configure authorization for your data warehouse in the *Amazon Redshift Management Guide*.
    > Modifying case sensitivity for a *provisioned* Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.
    > If your selected source and target are in different AWS accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

11. Once your target data warehouse is configured correctly, choose **Next**.
12. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging RDS resources".
13. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an AWS owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon Aurora resources".

> **Note**
>
> If you specify a custom KMS key, the key policy must allow the `kms:CreateGrant` action for the Amazon Redshift service principal (`redshift.amazonaws.com`). For more information, see Creating a key policy in the *AWS Key Management Service Developer Guide*.

Optionally, add an encryption context. For more information, see Encryption context in the *AWS Key Management Service Developer Guide*.

14. Choose **Next**.
15. Review your integration settings and choose **Create zero-ETL integration**.

    If creation fails, see the section called “I can't create a zero-ETL integration” for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon Redshift data warehouse has a status of `Modifying`. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to `Active`.

AWS CLI

> **Note**
>
> During the preview of Aurora PostgreSQL zero-ETL integrations, you can only create integrations through the AWS Management Console. You can't use the AWS CLI, the Amazon RDS API, or any of the SDKs.

To create a zero-ETL integration using the AWS CLI, use the create-integration command with the following options:

- `--integration-name` – Specify a name for the integration.

- `--source-arn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:my-db \
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:my-db ^
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

RDS API

> **Note**
>
> During the preview of Aurora PostgreSQL zero-ETL integrations, you can only create integrations through the AWS Management Console. You can't use the AWS CLI, the Amazon RDS API, or any of the SDKs.

To create a zero-ETL integration by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Next steps

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source Aurora DB cluster and querying it in Amazon Redshift. For instructions, see Creating destination databases in Amazon Redshift.

Data filtering for Aurora zero-ETL integrations with Amazon Redshift

You can use data filtering for Aurora zero-ETL integrations to define the scope of replication from the source Aurora DB cluster to the target Amazon Redshift data warehouse. Rather than replicating *all* data to the target, you can define one or more filters that selectively include or exclude certain tables from being replicated. Only filtering at the database and table level is available for zero-ETL integrations. You can't filter by columns or rows.

Data filtering can be useful when you want to:

- Join certain tables from two or more different source clusters and you don't need complete data from either cluster.
- Save costs by performing analytics using only a subset of tables rather than an entire fleet of databases.
- Filter out sensitive information—such as phone numbers, addresses, or credit card details—from certain tables.

You can add data filters to a zero-ETL integration using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API.

If the integration has a provisioned Amazon Redshift cluster as its target, the cluster must be on patch 180 or higher.

> **Note**
>
> Currently, you can perform data filtering only on integrations that have Aurora MySQL sources. The preview release of Aurora PostgreSQL zero-ETL integrations with Amazon Redshift doesn't support data filtering.

Topics

Format of a data filter

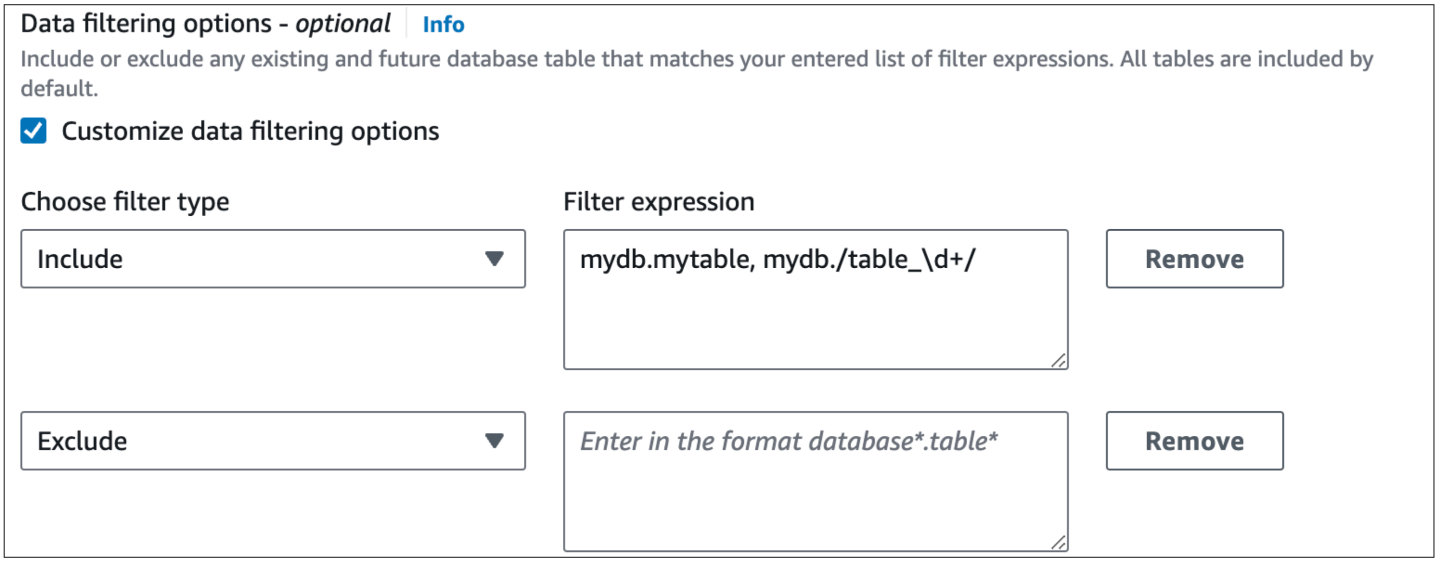
You can define multiple filters for a single integration. Each filter either includes or excludes any existing and future database tables that match one of the patterns in the filter expression. Aurora zero-ETL integrations use Maxwell filter syntax for data filtering.

Each filter has the following elements:

Element	Description
Filter type	An `Include` filter type *includes* all tables that match one of the patterns in the filter expression. An `Exclude` filter type *excludes* all tables that match one of the patterns.
Filter expression	A comma-separated list of patterns. Expressions must use Maxwell filter syntax.
Pattern	A filter pattern in the format *`database`*`.`*`table`*. You can specify literal database and table names (such as `mydb.mytable` , or use wildcards (*). You can also define regular expressions in the database and table name. Aurora supports filtering only at the database and table level. You can't include column-level filters (`database.`

Element	Description
	`table.column`) or blacklists (`blacklist: bad_db.*`). A single integration can have a maximum of 99 total patterns. In the console, you can contain patterns within a single filter expression, or spread them out among multiple expressions. A single pattern can't exceed 256 characters in length.

The following image shows the structure of data filters in the console:



Data filtering options - *optional* Info

Include or exclude any existing and future database table that matches your entered list of filter expressions. All tables are included by default.

☑ Customize data filtering options

Choose filter type	Filter expression
Include	mydb.mytable, mydb./table_\d+/
Exclude	*Enter in the format database*.table**

> **Important**
>
> Do not include personally identifying, confidential, or sensitive information in your filter patterns.

Data filters in the AWS CLI

When using the AWS CLI to add a data filter, the syntax differs slightly compared to the console. Each individual pattern must be associated with its own filter type (`Include` or `Exclude`). You can't group multiple patterns with a single filter type.

For example, in the console you can group the following comma-separated patterns within a single `Include` statement:

```
mydb.mytable, mydb./table_\d+/
```

However, when using the AWS CLI, the same data filter must be in the following format:

```
'include: mydb.mytable, include: mydb./table_\d+/'
```

Filter logic

If you don't specify any data filters in your integration, Aurora assumes a default filter of `include:*.*` and replicates all tables to the target data warehouse. However, if you specify at least one filter, the logic starts with an assumed `exclude:*.*`, meaning that all tables are automatically *excluded* from replication. This allows you to directly define which tables and databases to include.

For example, if you define the following filter:

```
'include: db.table1, include: db.table2'
```

Aurora evaluates the filter as follows:

```
'exclude:*.*, include: db.table1, include: db.table2'
```

Therefore, only `table1` and `table2` from the database named `db` are replicated to the target data warehouse.

Filter precedence

Aurora evaluates data filters in the order in which they're specified. In the AWS Management Console, this means that Aurora evaluates filter expressions from left to right and from top to bottom. If you specify a certain pattern for the first filter, then a second filter or even an individual pattern specified immediately after it can override it.

For example, your first filter might be `Include books.stephenking`, which includes a single table named `stephenking` from within the `books` database. However, if you add a second filter of Exclude books.*, it overrides the Include filter defined before it. Thus, no tables from the books index are replicated to Amazon Redshift.

If you specify at least one filter, the logic starts with an assumed exclude:*.*, meaning that all tables are automatically *excluded* from replication. Therefore, as a general best practice, define your filters from most broad to least broad. For example, use one or more Include statements to define all of the data that you want to replicate. Then, begin adding Exclude filters to selectively exclude certain tables from being replicated.

The same principle applies to filters that you define using the AWS CLI. Aurora evaluates these filter patterns in the order that they're specified, so a pattern might override one specified before it.

Examples

The following examples demonstrate how data filtering works for zero-ETL integrations:

- Include all databases and all tables:

  ```
  'include: *.*'
  ```

- Include all tables within the books database:

  ```
  'include: books.*'
  ```

- Exclude any tables named mystery:

  ```
  'include: *.*, exclude: *.mystery'
  ```

- Include two specific tables within the books database:

  ```
  'include: books.stephen_king, include: books.carolyn_keene'
  ```

- Include all tables in the books database, except for those containing the substring mystery:

  ```
  'include: books.*, exclude: books./.*mystery.*/
  ```

- Include all tables in the books database, except those starting with mystery:

  ```
  'include: books.*, exclude: books./mystery.*/'
  ```

- Include all tables in the books database, except those ending with mystery:

```
'include: books.*, exclude: books./.*mystery/'
```

- Include all tables in the books database that start with table_, except for the one named table_stephen_king. For example, table_movies or table_books would be replicated, but not table_stephen_king.

```
'include: books./table_.*/, exclude: books.table_stephen_king'
```

Adding data filters to an integration

You can configure data filtering using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

> ⚠ **Important**
>
> If you add a filter after creating an integration, then Aurora reevaluates the filter as if it always existed. It removes any data that is currently in the target Amazon Redshift data warehouse that doesn't match the new filtering criteria. This action causes all affected tables to resynchronize.

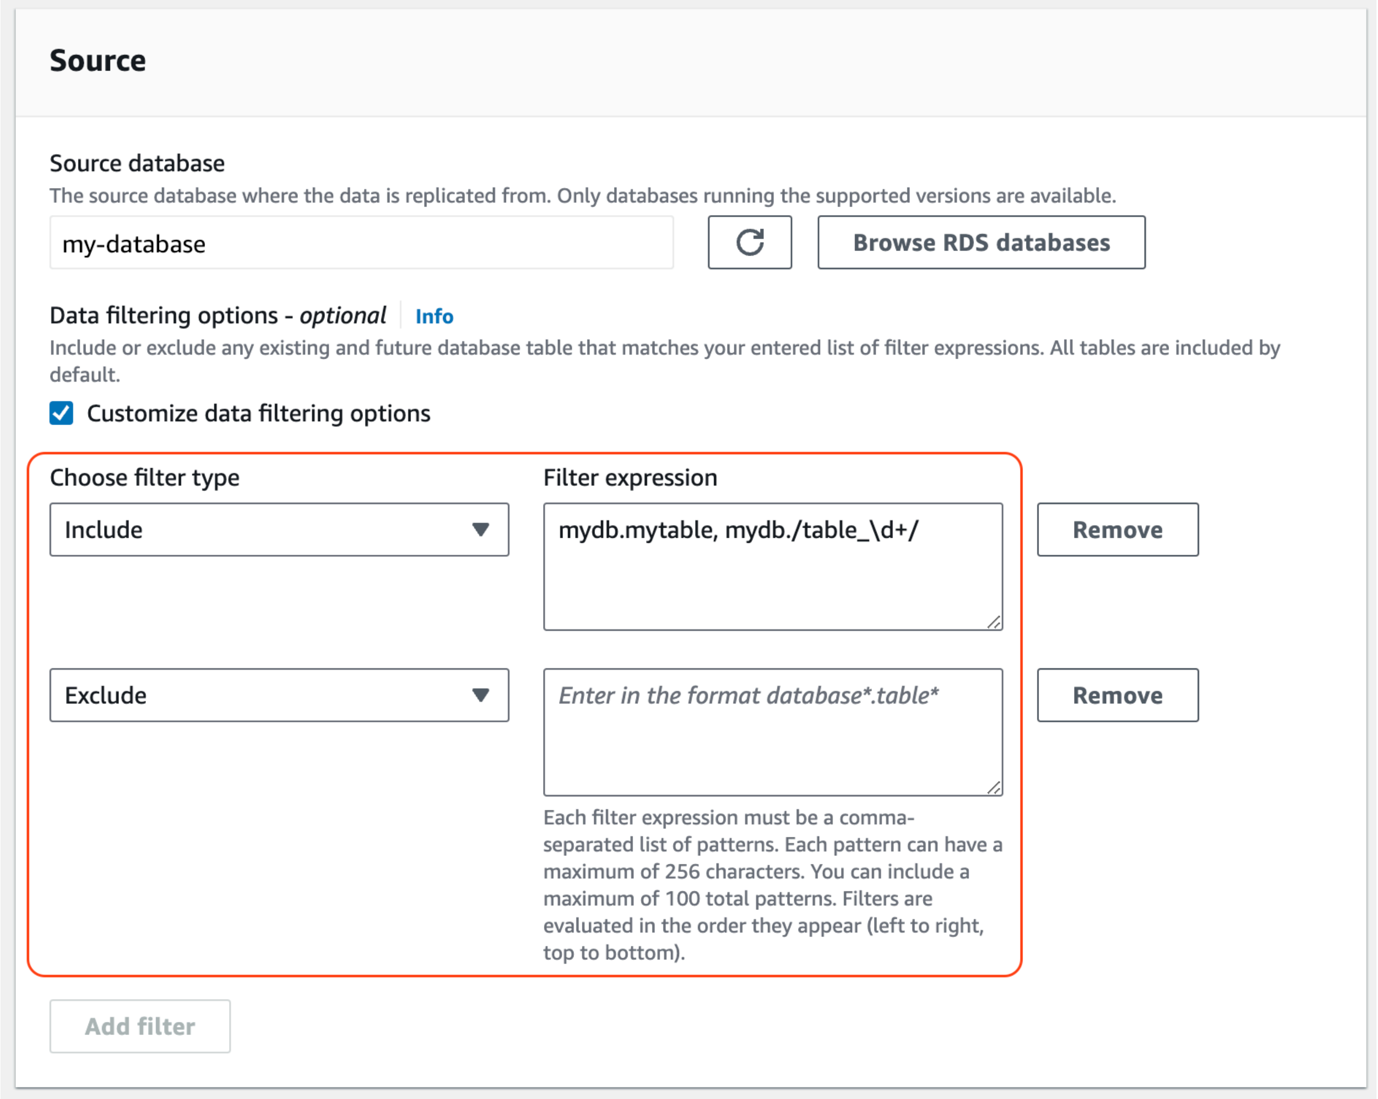
Currently, you can only perform data filtering on integrations that have Aurora MySQL sources. The preview release of Aurora PostgreSQL zero-ETL integrations with Amazon Redshift doesn't support data filtering.

RDS console

To add data filters to a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**. Select the integration that you want to add data filters to, and then choose **Modify**.
3. Under **Source**, add one or more Include and Exclude statements.

   The following image shows an example of data filters for an integration:



Source

Source database

The source database where the data is replicated from. Only databases running the supported versions are available.

my-database

Data filtering options - *optional* Info

Include or exclude any existing and future database table that matches your entered list of filter expressions. All tables are included by default.

☑ Customize data filtering options

Choose filter type	Filter expression	
Include	mydb.mytable, mydb./table_\d+/	Remove
Exclude	*Enter in the format database*.table**	Remove

Each filter expression must be a comma-separated list of patterns. Each pattern can have a maximum of 256 characters. You can include a maximum of 100 total patterns. Filters are evaluated in the order they appear (left to right, top to bottom).

4. When all the changes are as you want them, choose **Continue** and **Save changes**.

AWS CLI

To add data filters to a zero-ETL integration using the AWS CLI, call the modify-integration command. In addition to the integration identifier, specify the `--data-filter` parameter with a comma-separated list of `Include` and `Exclude` Maxwell filters.

Example

The following example adds filter patterns to `my-integration`.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier my-integration \
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier my-integration ^
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier and provide a comma-separated list of filter patterns.

Removing data filters from an integration

When you remove a data filter from an integration, Aurora reevaluates the remaining filters as if the removed filter never existed. Aurora then replicates any data that previously didn't match the filtering criteria (but now does) into the target Amazon Redshift data warehouse.

Removing one or more data filters causes all affected tables to resynchronize.

Adding data to a source Aurora DB cluster and querying it in Amazon Redshift

To finish creating a zero-ETL integration that replicates data from Amazon Aurora into Amazon Redshift, you must create a destination database in Amazon Redshift.

First, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source Aurora DB cluster and see it replicated in Amazon Redshift.

Topics

Creating a destination database in Amazon Redshift

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a destination database in your target data warehouse. This destination database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see Create a destination database in Amazon Redshift.

Adding data to the source DB cluster

After you configure your integration, you can add some data to the Aurora DB cluster that you want to replicate into your Amazon Redshift data warehouse.

> **Note**
>
> There are differences between data types in Amazon Aurora and Amazon Redshift. For a table of data type mappings, see the section called “Data type differences”.

First, connect to the source DB cluster using the MySQL or PostgreSQL client of your choice. For instructions, see the section called “Connecting to a DB cluster”.

Then, create a table and insert a row of sample data.

> **Important**
>
> Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

The pg_dump and pg_restore PostgreSQL utilities initially create tables without a primary key and then add it afterwards. If you're using one of these utilities, we recommend first creating a schema and then loading data in a separate command.

MySQL

The following example uses the MySQL Workbench utility.

```
CREATE DATABASE my_db;
```

```
USE my_db;

CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author
 VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural
 fiction');
```

PostgreSQL

The following example uses the psql PostgreSQL interactive terminal. When connecting to the cluster, include the named database that you specified when creating the integration.

```
psql -h mycluster.cluster-123456789012.us-east-2.rds.amazonaws.com -p 5432 -U username
 -d named_db;

named_db=> CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL,
 Author VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

named_db=> INSERT INTO books_table VALUES (1, "The Shining", "Stephen King", 1977,
 "Supernatural fiction");
```

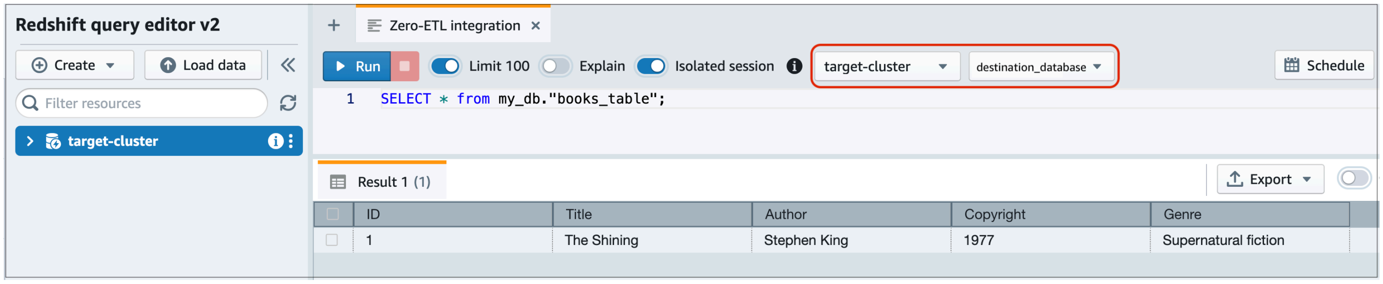
Querying your Aurora data in Amazon Redshift

After you add data to the Aurora DB cluster, it's replicated into Amazon Redshift and is ready to be queried.

To query the replicated data

1. Navigate to the Amazon Redshift console and choose **Query editor v2** from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (**destination_database** in this example). For instructions to create a destination database, see Create a destination database in Amazon Redshift.
3. Use a SELECT statement to query your data. In this example, you can run the following command to select all data from the table that you created in the source Aurora DB cluster:

```
SELECT * from my_db."books_table";
```



```
SELECT * from my_db."books_table";
```

ID	Title	Author	Copyright	Genre
1	The Shining	Stephen King	1977	Supernatural fiction

- *my_db* is the Aurora database schema name. This option is only needed for MySQL databases.
- *books_table* is the Aurora table name.

You can also query the data using the a command line client. For example:

```
destination_database=# select * from my_db."books_table";

 ID |       Title |         Author |   Copyright |                  Genre |  txn_seq |
 txn_id
----+-------------+----------------+-------------+------------------------+----------
+--------+
  1 | The Shining |  Stephen King |        1977 |   Supernatural fiction |        2 |
 12192
```

Note

For case-sensitivity, use double quotes (" ") for schema, table, and column names. For more information, see enable_case_sensitive_identifier.

Data type differences between Aurora and Amazon Redshift databases

The following tables show the mappings of an Aurora MySQL or Aurora PostgreSQL data type to a corresponding Amazon Redshift data type. *Amazon Aurora currently supports only these data types for zero-ETL integrations.*

If a table in your source DB cluster includes an unsupported data type, the table goes out of sync and isn't consumable by the Amazon Redshift target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in Amazon Redshift, you must manually revert the breaking change and then refresh the integration by running `ALTER DATABASE...INTEGRATION REFRESH`.

YEAR	VARCHAR(4)	Variable-length string value up to 4 bytes	
JSON	SUPER	Semistruc tured data or documents as values	

Aurora PostgreSQL

Zero-ETL integrations for Aurora PostgreSQL don't support custom data types or data types created by extensions.

⚠ **Important**

The zero-ETL integrations with Amazon Redshift feature for Aurora PostgreSQL is in preview release. The documentation and the feature are both subject to change. You can use this feature only in test environments, not in production environments. For preview terms and conditions, see *Betas and Previews* in AWS Service Terms.

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
bigint	BIGINT	Signed eight-byte integer	
bigserial	BIGINT	Signed eight-byte integer	
bit(n)	VARBYTE(n)	Variable-length binary value	
bit varying(n)	VARBYTE(n)	Variable-length binary value	
bit	VARBYTE(1024000)	Variable-length string value up to 1,024,000 bytes	
boolean	BOOLEAN	Logical boolean (true/false)	
bytea	VARBYTE(1024000)	Variable-length string value up to 1,024,000 bytes	
character(n)	CHAR(n)	Fixed-length character string	
character varying(n)	VARCHAR(65535)	Variable-length string value	

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
date	DATE	Calendar date (year, month, day)	• Values greater than 9999-12-31 not supported • B.C. values not supported
double precision	DOUBLE PRECISION	Double precision floating-point numbers	Subnormal values not supported
integer	INTEGER	Signed four-byte integer	
money	DECIMAL(20,3)	Currency amount	
numeric(p,s)	DECIMAL(p,s)	Variable-length string value	• NaN values not supported • Precision greater than 38 and scale greater than 37 not supported • Negative scale not supported
real	REAL	Single precision floating-point number	
smallint	SMALLINT	Signed two-byte integer	

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
smallserial	SMALLINT	Signed two-byte integer	
serial	INTEGER	Signed four-byte integer	
text	VARCHAR(65535)	Variable-length string value up to 65,535 bytes	
time [(p)] [without time zone]	VARCHAR(19)	Variable-length string value up to 19 bytes	`Infinity` and `-Infinity` values not supported
time [(p)] with time zone	VARCHAR(22)	Variable-length string value up to 22 bytes	• `Infinity` and -`Infinity` values not supported
timestamp [(p)] [without timezone]	TIMESTAMP	Date and time (without time zone)	• `Infinity` and -`Infinity` values not supported • Values greater than `9999-12-31` not supported • B.C. values not supported

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
timestamp [(p)] with time zone	TIMESTAMPTZ	Date and time (with time zone)	• `Infinity` and - `Infinity` values not supported • Values greater than `9999-12-31` not supported • B.C. values not supported

Viewing and monitoring Aurora zero-ETL integrations with Amazon Redshift

You can view the details of an Amazon Aurora zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

Topics

- Viewing integrations
- Monitoring integrations using system tables
- Monitoring integrations with Amazon EventBridge

Viewing integrations

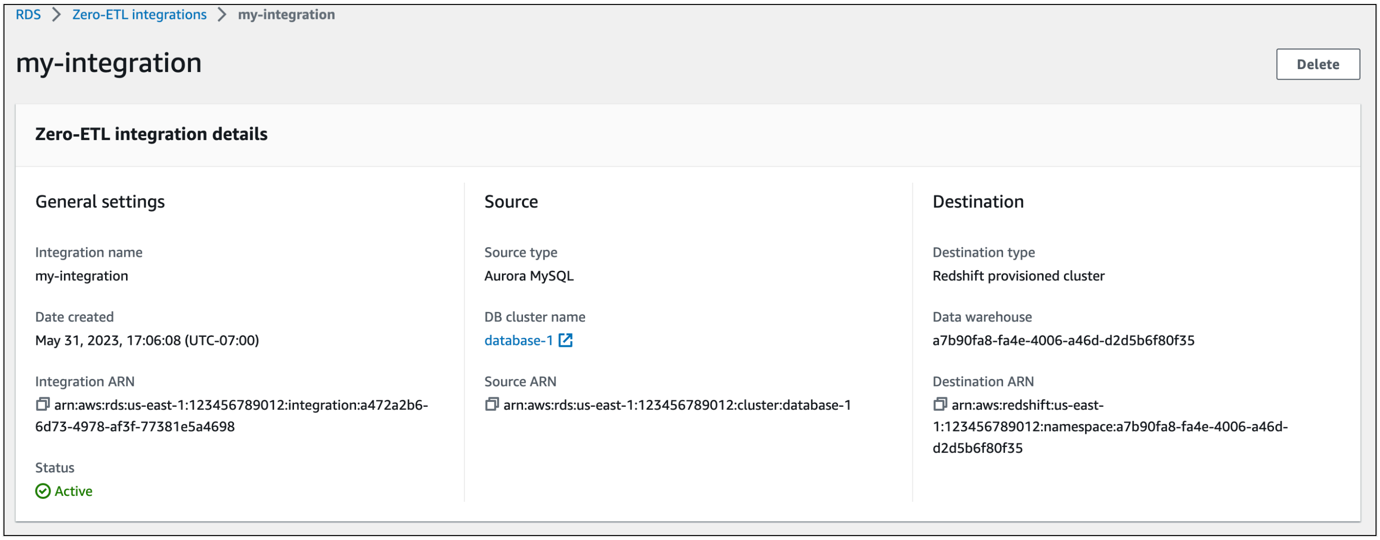
You can view Aurora zero-ETL integrations with Amazon Redshift using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the details of a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   If the integration has an Aurora PostgreSQL source DB cluster, you must sign in to the Amazon RDS Database Preview Environment at https://us-east-2.console.aws.amazon.com/rds-preview/home?region=us-east-2#databases.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select an integration to view more details about it, such as its source DB cluster and target data warehouse.



my-integration

Zero-ETL integration details

General settings

Integration name
my-integration

Date created
May 31, 2023, 17:06:08 (UTC-07:00)

Integration ARN
arn:aws:rds:us-east-1:123456789012:integration:a472a2b6-6d73-4978-af3f-77381e5a4698

Status
Active

Source

Source type
Aurora MySQL

DB cluster name
database-1

Source ARN
arn:aws:rds:us-east-1:123456789012:cluster:database-1

Destination

Destination type
Redshift provisioned cluster

Data warehouse
a7b90fa8-fa4e-4006-a46d-d2d5b6f80f35

Destination ARN
arn:aws:redshift:us-east-1:123456789012:namespace:a7b90fa8-fa4e-4006-a46d-d2d5b6f80f35

An integration can have the following statuses:

- `Creating` – The integration is being created.
- `Active` – The integration is sending transactional data to the target data warehouse.
- `Syncing` – The integration has encountered a recoverable error and is reseeding data. Affected tables aren't available for querying in Amazon Redshift until they finish resyncing.
- `Needs attention` – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- `Failed` – The integration encountered an unrecoverable event or error that can't be fixed. You must delete and recreate the integration.

- Deleting – The integration is being deleted.

AWS CLI

To view all zero-ETL integrations in the current account using the AWS CLI, use the describe-integrations command and specify the --integration-identifier option.

Example

For Linux, macOS, or Unix:

```
aws rds describe-integrations \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds describe-integrations ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To view zero-ETL integration using the Amazon RDS API, use the DescribeIntegrations operation with the IntegrationIdentifier parameter.

Monitoring integrations using system tables

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database table. For more information about system tables and views in Amazon Redshift, see System tables reference in the *Amazon Redshift Database Developer Guide*.

You can query the following system views and tables to get information about your Aurora zero-ETL integrations with Amazon Redshift:

- SVV_INTEGRATION – Provides configuration details for your integrations.
- SVV_INTEGRATION_TABLE_STATE – Describes the state of each table within an integration.
- SYS_INTEGRATION_TABLE_STATE_CHANGE – Displays table state change logs for an integration.
- SYS_INTEGRATION_ACTIVITY – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see Monitoring zero-ETL integrations in the *Amazon Redshift Management Guide*. Currently, Amazon Aurora doesn't publish any integration metrics to CloudWatch.

Monitoring integrations with Amazon EventBridge

Amazon Redshift sends integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see Zero-ETL integration event notifications with Amazon EventBridge in the *Amazon Redshift Management Guide*.

Modifying Aurora zero-ETL integrations with Amazon Redshift

You can modify only the name, description, and data filtering options for a zero-ETL integration with Amazon Redshift. You can't modify the AWS KMS key used to encrypt the integration, or the source or target databases.

If you add a data filter to an existing integration, Aurora reevaluates the filter as if it always existed. It removes any data that is currently in the target Amazon Redshift data warehouse that doesn't match the new filtering criteria. If you *remove* a data filter from an integration, it replicates any data that previously didn't match the filtering criteria (but now does) into the target data warehouse. For more information, see the section called “Data filtering for zero-ETL integrations”.

You can modify a zero-ETL integration using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

> **Note**
>
> Currently, you can only modify integrations that have Aurora MySQL source DB clusters. Modifying integrations isn't supported for the preview release of Aurora PostgreSQL zero-ETL integrations with Amazon Redshift.

RDS console

To modify a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Zero-ETL integrations**, and then choose the integration that you want to modify.
3. Choose **Modify** and make modifications to any available settings.
4. When all the changes are as you want them, choose **Modify**.

AWS CLI

To modify a zero-ETL integration using the AWS CLI, call the modify-integration command. Along with the `--integration-identifier`, specify any of the following options:

- `--integration-name` – Specify a new name for the integration.
- `--description` – Specify a new description for the integration.
- `--data-filter` – Specify data filtering options for the integration. For more information, see the section called "Data filtering for zero-ETL integrations".

Example

The following request modifies an existing integration.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 \
    --integration-name my-renamed-integration
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 ^
    --integration-name my-renamed-integration
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier, and the parameters that you want to modify.

Deleting Aurora zero-ETL integrations with Amazon Redshift

When you delete a zero-ETL integration, Amazon Aurora removes it from the source Aurora DB cluster. Your transactional data isn't deleted from Amazon Aurora or Amazon Redshift, but Aurora doesn't send new data to Amazon Redshift.

You can only delete an integration when it has a status of `Active`, `Failed`, `Syncing`, or `Needs attention`.

You can delete zero-ETL integrations using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   If the integration has an Aurora PostgreSQL source DB cluster, you must sign in to the Amazon RDS Database Preview Environment at https://us-east-2.console.aws.amazon.com/rds-preview/home?region=us-east-2#databases.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select the zero-ETL integration that you want to delete.
4. Choose **Actions**, **Delete**, and confirm deletion.

AWS CLI

> **Note**
>
> During the preview of Aurora PostgreSQL zero-ETL integrations, you can only delete integrations through the AWS Management Console. You can't use the AWS CLI, the Amazon RDS API, or any of the SDKs.

To delete a zero-ETL integration, use the delete-integration command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds delete-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds delete-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

Note

During the preview of Aurora PostgreSQL zero-ETL integrations, you can only delete integrations through the AWS Management Console. You can't use the AWS CLI, the Amazon RDS API, or any of the SDKs.

To delete a zero-ETL integration using the Amazon RDS API, use the `DeleteIntegration` operation with the `IntegrationIdentifier` parameter.

Troubleshooting Aurora zero-ETL integrations with Amazon Redshift

You can check the state of a zero-ETL integration by querying the SVV_INTEGRATION system table in Amazon Redshift. If the `state` column has a value of `ErrorState`, it means something's wrong. For more information, see the section called “Monitoring using system tables”.

Use the following information to troubleshoot common issues with Aurora zero-ETL integrations with Amazon Redshift.

Topics

- I can't create a zero-ETL integration
- My integration is stuck in a state of Syncing

- My tables aren't replicating to Amazon Redshift
- One or more of my Amazon Redshift tables requires a resync

I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source DB cluster:

- Your source DB cluster is running Aurora MySQL version 3.05 (compatible with MySQL 8.0.32) or higher, or Aurora PostgreSQL (compatible with PostgreSQL 15.4 and Zero-ETL Support). To validate the engine version, choose the **Configuration** tab for the DB cluster and check the **Engine version**.
- You correctly configured DB cluster parameters. If the required parameters are set incorrectly or not associated with the cluster, creation fails. See the section called "Step 1: Create a custom DB cluster parameter group".

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See Turn on case sensitivity for your data warehouse.
- You added the correct authorized principal and integration source. See Configure authorization for your Amazon Redshift data warehouse.
- The data warehouse is encrypted (if it's a provisioned cluster). See Amazon Redshift database encryption.

My integration is stuck in a state of `Syncing`

Your integration might consistently show a status of `Syncing` if you change the value of one of the required DB parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source DB cluster, and make sure that they match the required values. For more information, see the section called "Step 1: Create a custom DB cluster parameter group".

If you modify any parameters, make sure to reboot the DB cluster to apply the changes.

My tables aren't replicating to Amazon Redshift

Your data might not be replicating because one or more of your source tables doesn't have a primary key. The monitoring dashboard in Amazon Redshift displays the status of these tables as `Failed`, and the status of the overall zero-ETL integration changes to `Needs attention`.

To resolve this issue, you can identify an existing key in your table that can become a primary key, or you can add a synthetic primary key. For detailed solutions, see the following resources:

- Handle tables without primary keys while creating Amazon Aurora MySQL or Amazon RDS for MySQL zero-ETL integrations with Amazon Redshift
- Handle tables without primary keys while creating Amazon Aurora PostgreSQL zero-ETL integrations with Amazon Redshift

One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source DB cluster might require your tables to be resynchronized. In these cases, the SVV_INTEGRATION_TABLE_STATE system view shows a `table_state` of `ResyncRequired`, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of `Syncing`. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you can't access it in Amazon Redshift.

The following are some example operations that can put a table into a `ResyncRequired` state, and possible alternatives to consider.

Operation	Example	Alternative

Adding a column into a specific position	`ALTER TABLE table_name`
	`  ADD COLUMN column_name  INTEGER`
	`  NOT NULL first;`
		Amazon Redshift doesn't support adding columns into specific positions

Operation	Example	Alternative
		using `first` or `after` keywords. If the order of columns in the target table isn't critical, add the column to the end of the table using a simpler command: `ALTER TABLE table_name ADD COLUMN column_name column_type ;`

Operation	Example	Alternative

Adding a timestamp column with the default `CURRENT_TIMESTAMP`	`ALTER TABLE table_name`
	`  ADD COLUMN column_name  TIMESTAMP`
	`  NOT NULL DEFAULT CURRENT_TIMESTAMP;`
		The `CURRENT_TIMESTAMP` value for existing table rows is calculated by Aurora MySQL and can't be simulated in Amazon Redshift without full table data resynchronization.
		If possible, switch the default value to a literal constant like `2023-01-01 00:00:15` to avoid latency in table availability.

Operation	Example	Alternative

Performing multiple column operations within a single command	`ALTER TABLE table_name`
	`  ADD COLUMN column_1,`
	`  RENAME COLUMN column_2 TO column_3;`
		Consider splitting the command into two separate operations, `ADD` and `RENAME`, which won't require resynchronization.

Using Aurora Serverless v2

Aurora Serverless v2 is an on-demand, autoscaling configuration for Amazon Aurora. Aurora Serverless v2 helps to automate the processes of monitoring the workload and adjusting the capacity for your databases. Capacity is adjusted automatically based on application demand. You're charged only for the resources that your DB clusters consume. Thus, Aurora Serverless v2 can help you to stay within budget and avoid paying for computer resources that you don't use.

This type of automation is especially valuable for multitenant databases, distributed databases, development and test systems, and other environments with highly variable and unpredictable workloads.

Topics

Aurora Serverless v2 use cases

Aurora Serverless v2 supports many types of database workloads. These range from development and testing environments, to websites and applications that have unpredictable workloads, to the most demanding, business-critical applications that require high scale and availability.

Aurora Serverless v2 is especially useful for the following use cases:

- **Variable workloads** – You're running workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. Another is an e-commerce site with increased traffic when you offer sales or special promotions. With Aurora Serverless v2, your database automatically scales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over. With Aurora Serverless v2, you no longer need to provision for peak or average capacity. You can specify an upper capacity limit to handle the worst-case situation, and that capacity isn't used unless it's needed.

The granularity of scaling in Aurora Serverless v2 helps you to match capacity closely to your database's needs. For a provisioned cluster, scaling up requires adding a whole new DB instance. For an Aurora Serverless v1 cluster, scaling up requires doubling the number of Aurora capacity units (ACUs) for the cluster, such as from 16 to 32 or 32 to 64. In contrast, Aurora Serverless v2 can add half an ACU when only a little more capacity is needed. It can add 0.5, 1, 1.5, 2, or additional half-ACUs based on the additional capacity needed to handle an increase in workload. And it can remove 0.5, 1, 1.5, 2, or additional half-ACUs when the workload decreases and that capacity is no longer needed.

- **Multi-tenant applications –** With Aurora Serverless v2, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v2 manages individual database capacity for you.

  You can create a cluster for each tenant. That way, you can use features such as cloning, snapshot restore, and Aurora global databases to enhance high availability and disaster recovery as appropriate for each tenant.

  Each tenant might have specific busy and idle periods depending on the time of day, time of year, promotional events, and so on. Each cluster can have a wide capacity range. That way, clusters with low activity incur minimal DB instance charges. Any cluster can quickly scale up to handle periods of high activity.
- **New applications –** You're deploying a new application and you're unsure about the DB instance size you need. By using Aurora Serverless v2, you can set up a cluster with one or many DB instances and have the database autoscale to the capacity requirements of your application.
- **Mixed-use applications –** Suppose that you have an online transaction processing (OLTP) application, but you periodically experience spikes in query traffic. By specifying promotion tiers for the Aurora Serverless v2 DB instances in a cluster, you can configure your cluster so that the reader DB instances can scale independently of the writer DB instance to handle the additional load. When the usage spike subsides, the reader DB instances scale back down to match the capacity of the writer DB instance.
- **Capacity planning –** Suppose that you usually adjust your database capacity, or verify the optimal database capacity for your workload, by modifying the DB instance classes of all the DB instances in a cluster. With Aurora Serverless v2, you can avoid this administrative overhead. You

can determine the appropriate minimum and maximum capacity by running the workload and checking how much the DB instances actually scale.

You can modify existing DB instances from provisioned to Aurora Serverless v2 or from Aurora Serverless v2 to provisioned. You don't need to create a new cluster or a new DB instance in such cases.

With an Aurora global database, you might not need as much capacity for the secondary clusters as in the primary cluster. You can use Aurora Serverless v2 DB instances in the secondary clusters. That way, the cluster capacity can scale up if a secondary region is promoted and takes over your application's workload.

- **Development and testing** – In addition to running your most demanding applications, you can also use Aurora Serverless v2 for development and testing environments. With Aurora Serverless v2, you can create DB instances with a low minimum capacity instead of using burstable db.t* DB instance classes. You can set the maximum capacity high enough that those DB instances can still run substantial workloads without running low on memory. When the database isn't in use, all of the DB instances scale down to avoid unnecessary charges.

> **Tip**
>
> To make it convenient to use Aurora Serverless v2 in development and test environments, the AWS Management Console provides the **Easy create** shortcut when you create a new cluster. If you choose the **Dev/Test** option, Aurora creates a cluster with an Aurora Serverless v2 DB instance and a capacity range that's typical for a development and test system.

Using Aurora Serverless v2 for existing provisioned workloads

Suppose that you already have an Aurora application running on a provisioned cluster. You can check how the application would work with Aurora Serverless v2 by adding one or more Aurora Serverless v2 DB instances to the existing cluster as reader DB instances. You can check how often the reader DB instances scale up and down. You can use the Aurora failover mechanism to promote an Aurora Serverless v2 DB instance to be the writer and check how it handles the read/write workload. That way, you can switch over with minimal downtime and without changing the endpoint that your client applications use. For details on the procedure to convert existing clusters to Aurora Serverless v2, see Migrating to Aurora Serverless v2.

Advantages of Aurora Serverless v2

Aurora Serverless v2 is intended for variable or "spiky" workloads. With such unpredictable workloads, you might have difficulty planning when to change your database capacity. You might also have trouble making capacity changes quickly enough using the familiar mechanisms such as adding DB instances or changing DB instance classes. Aurora Serverless v2 provides the following advantages to help with such use cases:

- **Simpler capacity management than provisioned –** Aurora Serverless v2 reduces the effort for planning DB instance sizes and resizing DB instances as the workload changes. It also reduces the effort for maintaining consistent capacity for all the DB instances in a cluster.
- **Faster and easier scaling during periods of high activity –** Aurora Serverless v2 scales compute and memory capacity as needed, with no disruption to client transactions or your overall workload. The ability to use reader DB instances with Aurora Serverless v2 helps you to take advantage of horizontal scaling in addition to vertical scaling. The ability to use Aurora global databases means that you can spread your Aurora Serverless v2 read workload across multiple AWS Regions. This capability is more convenient than the scaling mechanisms for provisioned clusters. It's also faster and more granular than the scaling capabilities in Aurora Serverless v1.
- **Cost-effective during periods of low activity –** Aurora Serverless v2 helps you to avoid overprovisioning your DB instances. Aurora Serverless v2 adds resources in granular increments when DB instances scale up. You pay only for the database resources that you consume. Aurora Serverless v2 resource usage is measured on a per-second basis. That way, when a DB instance scales down, the reduced resource usage is registered right away.
- **Greater feature parity with provisioned –** You can use many Aurora features with Aurora Serverless v2 that aren't available for Aurora Serverless v1. For example, with Aurora Serverless v2 you can use reader DB instances, global databases, AWS Identity and Access Management (IAM) database authentication, and Performance Insights. You can also use many more configuration parameters than with Aurora Serverless v1.

  In particular, with Aurora Serverless v2 you can take advantage of the following features from provisioned clusters:

  - **Reader DB instances –** Aurora Serverless v2 can take advantage of reader DB instances to scale horizontally. When a cluster contains one or more reader DB instances, the cluster can fail over immediately in case of problems with the writer DB instance. This is a capability that isn't available with Aurora Serverless v1.

  - **Multi-AZ clusters –** You can distribute the Aurora Serverless v2 DB instances of a cluster across multiple Availability Zones (AZs). Setting up a Multi-AZ cluster helps to ensure business continuity even in the rare case of issues that affect an entire AZ. This is a capability that isn't available with Aurora Serverless v1.
  - **Global databases –** You can use Aurora Serverless v2 in combination with Aurora global databases to create additional read-only copies of your cluster in other AWS Regions for disaster recovery purposes.
  - **RDS Proxy –** You can use Amazon RDS Proxy to allow your applications to pool and share database connections to improve their ability to scale.
- **Faster, more granular, less disruptive scaling than Aurora Serverless v1 –** Aurora Serverless v2 can scale up and down faster. Scaling can change capacity by as little as 0.5 ACUs, instead of doubling or halving the number of ACUs. Scaling typically happens with no pause in processing at all. Scaling doesn't involve an event that you have to be aware of, as with Aurora Serverless v1. Scaling can happen while SQL statements are running and transactions are open, without the need to wait for a quiet point.

How Aurora Serverless v2 works

The following overview describes how Aurora Serverless v2 works.

Topics

Aurora Serverless v2 overview

Amazon Aurora Serverless v2 is suitable for the most demanding, highly variable workloads. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail, gaming, or sports websites with periodic promotional events, and databases that produce reports when needed. Others are development and testing environments, and new applications where usage might ramp up quickly. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

In contrast, *Aurora provisioned clusters* are suitable for steady workloads. With provisioned clusters, you choose a DB instance class that has a predefined amount of memory, CPU power, I/O bandwidth, and so on. If your workload changes, you manually modify the instance class of your writer and readers. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns and it's acceptable to have brief outages while you change the instance class of the writer and readers in your cluster.

Aurora Serverless v2 is architected from the ground up to support serverless DB clusters that are instantly scalable. Aurora Serverless v2 is engineered to provide the same degree of security and isolation as with provisioned writers and readers. These aspects are crucial in multitenant serverless cloud environments. The dynamic scaling mechanism has very little overhead so that it can respond quickly to changes in the database workload. It's also powerful enough to meet dramatic increases in processing demand.

By using Aurora Serverless v2, you can create an Aurora DB cluster without being locked into a specific database capacity for each writer and reader. You specify the minimum and maximum capacity range. Aurora scales each Aurora Serverless v2 writer or reader in the cluster within that capacity range. By using a Multi-AZ cluster where each writer or reader can scale dynamically, you can take advantage of dynamic scaling and high availability.

Aurora Serverless v2 scales the database resources automatically based on your minimum and maximum capacity specifications. Scaling is fast because most scaling events operations keep the writer or reader on the same host. In the rare cases that an Aurora Serverless v2 writer or reader is moved from one host to another, Aurora Serverless v2 manages the connections automatically. You don't need to change your database client application code or your database connection strings.

With Aurora Serverless v2, as with provisioned clusters, storage capacity and compute capacity are separate. When we refer to Aurora Serverless v2 capacity and scaling, it's always compute capacity that's increasing or decreasing. Thus, your cluster can contain many terabytes of data even when the CPU and memory capacity scale down to low levels.

Instead of provisioning and managing database servers, you specify database capacity. For details about Aurora Serverless v2 capacity, see Aurora Serverless v2 capacity. The actual capacity of each

Aurora Serverless v2 writer or reader varies over time, depending on your workload. For details about that mechanism, see Aurora Serverless v2 scaling.

⚠ **Important**

With Aurora Serverless v1, your cluster has a single measure of compute capacity that can scale between the minimum and maximum capacity values. With Aurora Serverless v2, your cluster can contain readers in addition to the writer. Each Aurora Serverless v2 writer and reader can scale between the minimum and maximum capacity values. Thus, the total capacity of your Aurora Serverless v2 cluster depends on both the capacity range that you define for your DB cluster and the number of writers and readers in the cluster. At any specific time, you are only charged for the Aurora Serverless v2 capacity that is being actively used in your Aurora DB cluster.

Configurations for Aurora DB clusters

For each of your Aurora DB clusters, you can choose any combination of Aurora Serverless v2 capacity, provisioned capacity, or both.

You can set up a cluster that contains both Aurora Serverless v2 and provisioned capacity, called a *mixed-configuration cluster*. For example, suppose that you need more read/write capacity than is available for an Aurora Serverless v2 writer. In this case, you can set up the cluster with a very large provisioned writer. In that case, you can still use Aurora Serverless v2 for the readers. Or suppose that the write workload for your cluster varies but the read workload is steady. In this case, you can set up your cluster with an Aurora Serverless v2 writer and one or more provisioned readers.

You can also set up a DB cluster where all the capacity is managed by Aurora Serverless v2. To do this, you can create a new cluster and use Aurora Serverless v2 from the start. Or you can replace all the provisioned capacity in an existing cluster with Aurora Serverless v2. For example, some of the upgrade paths from older engine versions require starting with a provisioned writer and replacing it with a Aurora Serverless v2 writer. For the procedures to create a new DB cluster with Aurora Serverless v2 or to switch an existing DB cluster to Aurora Serverless v2, see Creating an Aurora Serverless v2 DB cluster and Switching from a provisioned cluster to Aurora Serverless v2.

If you don't use Aurora Serverless v2 at all in a DB cluster, all the writers and readers in the DB cluster are *provisioned*. This is the oldest and most common kind of DB cluster that most users are familiar with. In fact, before Aurora Serverless, there wasn't a special name for this kind of Aurora DB cluster. Provisioned capacity is constant. The charges are relatively easy to forecast. However, you have to predict in advance how much capacity you need. In some cases, your predictions might be inaccurate or your capacity needs might change. In these cases, your DB cluster can become underprovisioned (slower than you want) or overprovisioned (more expensive than you want).

Aurora Serverless v2 capacity

The unit of measure for Aurora Serverless v2 is the *Aurora capacity unit (ACU)*. Aurora Serverless v2 capacity isn't tied to the DB instance classes that you use for provisioned clusters.

Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. You specify the database capacity range using this unit of measure. The `ServerlessDatabaseCapacity` and `ACUUtilization` metrics help you to determine how much capacity your database is actually using and where that capacity falls within the specified range.

At any moment in time, each Aurora Serverless v2 DB writer or reader has a *capacity*. The capacity is represented as a floating-point number representing ACUs. The capacity increases or decreases whenever the writer or reader scales. This value is measured every second. For each DB cluster where you intend to use Aurora Serverless v2, you define a *capacity range*: the minimum and maximum capacity values that each Aurora Serverless v2 writer or reader can scale between. The capacity range is the same for each Aurora Serverless v2 writer or reader in a DB cluster. Each Aurora Serverless v2 writer or reader has its own capacity, falling somewhere in that range.

The largest Aurora Serverless v2 capacity that you can define is 128 ACUs. For all the considerations when choosing the maximum capacity value, see Choosing the maximum Aurora Serverless v2 capacity setting for a cluster.

The smallest Aurora Serverless v2 capacity that you can define is 0.5 ACUs. You can specify a higher number if it's less than or equal to the maximum capacity value. Setting the minimum capacity to a small number lets lightly loaded DB clusters consume minimal compute resources. At the same time, they stay ready to accept connections immediately and scale up when they become busy.

We recommend setting the minimum to a value that allows each DB writer or reader to hold the working set of the application in the buffer pool. That way, the contents of the buffer pool aren't discarded during idle periods. For all the considerations when choosing the minimum capacity value, see Choosing the minimum Aurora Serverless v2 capacity setting for a cluster.

Depending on how you configure the readers in a Multi-AZ DB cluster, their capacities can be tied to the capacity of the writer or independently. For details about how to do that, see Aurora Serverless v2 scaling.

Monitoring Aurora Serverless v2 involves measuring the capacity values for the writer and readers in your DB cluster over time. If your database doesn't scale down to the minimum capacity, you can take actions such as adjusting the minimum and optimizing your database application. If your database consistently reaches its maximum capacity, you can take actions such as increasing the maximum. You can also optimize your database application and spread the query load across more readers.

The charges for Aurora Serverless v2 capacity are measured in terms of ACU-hours. For information about how Aurora Serverless v2 charges are calculated, see the Aurora pricing page.

Suppose that the total number of writers and readers in your cluster is N. In that case, the cluster consumes approximately `n x minimum ACUs` when you aren't running any database operations. Aurora itself might run monitoring or maintenance operations that cause some small amount of load. That cluster consumes no more than `n x maximum ACUs` when the database is running at full capacity.

For more details about choosing appropriate minimum and maximum ACU values, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster. The minimum and maximum ACU values that you specify also affect the way some of the Aurora configuration parameters work for Aurora Serverless v2. For details about the interaction between the capacity range and configuration parameters, see Working with parameter groups for Aurora Serverless v2.

Aurora Serverless v2 scaling

For each Aurora Serverless v2 writer or reader, Aurora continuously tracks utilization of resources such as CPU, memory, and network. These measurements collectively are called the *load*. The load includes the database operations performed by your application. It also includes background processing for the database server and Aurora administrative tasks. When capacity is constrained by any of these, Aurora Serverless v2 scales up. Aurora Serverless v2 also scales up when it detects performance issues that it can resolve by doing so. You can monitor resource utilization and how it affects Aurora Serverless v2 scaling by using the procedures in Important Amazon CloudWatch metrics for Aurora Serverless v2 and Monitoring Aurora Serverless v2 performance with Performance Insights.

The load can vary across the writer and readers in your DB cluster. The writer handles all data definition language (DDL) statements, such as `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`. The writer also handles all data manipulation language (DML) statements, such as `INSERT` and `UPDATE`. Readers can process read-only statements, such as `SELECT` queries.

Scaling is the operation that increases or decreases Aurora Serverless v2 capacity for your database. With Aurora Serverless v2, each writer and reader has its own current capacity value, measured in ACUs. Aurora Serverless v2 scales a writer or reader up to a higher capacity when its current capacity is too low to handle the load. It scales the writer or reader down to a lower capacity when its current capacity is higher than needed.

Unlike Aurora Serverless v1, which scales by doubling the capacity each time the DB cluster reaches a threshold, Aurora Serverless v2 can increase capacity incrementally. When your workload demand begins to reach the current database capacity of a writer or reader, Aurora Serverless v2 increases the number of ACUs for that writer or reader. Aurora Serverless v2 scales capacity in the increments required to provide the best performance for the resources consumed. Scaling happens in increments as small as 0.5 ACUs. The larger the current capacity, the larger the scaling increment and thus the faster scaling can happen.

Because Aurora Serverless v2 scaling is so frequent, granular, and nondisruptive, it doesn't cause discrete events in the AWS Management Console the way that Aurora Serverless v1 does. Instead, you can measure the Amazon CloudWatch metrics such as `ServerlessDatabaseCapacity` and `ACUUtilization` and track their minimum, maximum, and average values over time. To learn more about Aurora metrics, see Monitoring metrics in an Amazon Aurora cluster. For tips about monitoring Aurora Serverless v2, see Important Amazon CloudWatch metrics for Aurora Serverless v2.

You can choose to make a reader scale at the same time as the associated writer, or independently from the writer. You do so by specifying the promotion tier for that reader.

- Readers in promotion tiers 0 and 1 scale at the same time as the writer. That scaling behavior makes readers in priority tiers 0 and 1 ideal for availability. That's because they are always sized to the right capacity to take over the workload from the writer in case of failover.
- Readers in promotion tiers 2–15 scale independently from the writer. Each reader remains within the minimum and maximum ACU values that you specified for your cluster. When a reader scales independently of the associated writer DB, it can become idle and scale down while the writer continues to process a high volume of transactions. It's still available as a failover target, if no other readers are available in lower promotion tiers. However, if it's promoted to be the writer, it might need to scale up to handle the full workload of the writer.

For details about promotion tiers, see Choosing the promotion tier for an Aurora Serverless v2 reader.

The notions of scaling points and associated timeout periods from Aurora Serverless v1 don't apply in Aurora Serverless v2. Aurora Serverless v2 scaling can happen while database connections are open, while SQL transactions are in process, while tables are locked, and while temporary tables are in use. Aurora Serverless v2 doesn't wait for a quiet point to begin scaling. Scaling doesn't disrupt any database operations that are underway.

If your workload requires more read capacity than is available with a single writer and a single reader, you can add multiple Aurora Serverless v2 readers to the cluster. Each Aurora Serverless v2 reader can scale within the range of minimum and maximum capacity values that you specified for your DB cluster. You can use the cluster's reader endpoint to direct read-only sessions to the readers and reduce the load on the writer.

Whether Aurora Serverless v2 performs scaling, and how fast scaling occurs once it starts, also depends on the minimum and maximum ACU settings for the cluster. In addition, it depends on whether a reader is configured to scale along with the writer or independently from it. For details about the factors that affect Aurora Serverless v2 scaling, see Performance and scaling for Aurora Serverless v2.

Note

Currently, Aurora Serverless v2 writers and readers don't scale all the way down to zero ACUs. Idle Aurora Serverless v2 writers and readers can scale down to the minimum ACU value that you specified for the cluster.
That behavior is different than Aurora Serverless v1, which can pause after a period of idleness, but then takes some time to resume when you open a new connection. When your DB cluster with Aurora Serverless v2 capacity isn't needed for some time, you can stop and start clusters as with provisioned DB clusters. For details about stopping and starting clusters, see Stopping and starting an Amazon Aurora DB cluster.

Aurora Serverless v2 and high availability

The way to establish high availability for an Aurora DB cluster is to make it a Multi-AZ DB cluster. A *Multi-AZ Aurora DB cluster* has compute capacity available at all times in more than one Availability Zone (AZ). That configuration keeps your database up and running even in case of a significant outage. Aurora performs an automatic failover in case of an issue that affects the writer or even the entire AZ. With Aurora Serverless v2, you can choose for the standby compute capacity to scale up and down along with the capacity of the writer. That way, the compute capacity in the second

AZ is ready to take over the current workload at any time. At the same time, the compute capacity in all AZs can scale down when the database is idle. For details about how Aurora works with AWS Regions and Availability Zones, see High availability for Aurora DB instances.

The Aurora Serverless v2 Multi-AZ capability uses *readers* in addition to the writer. Support for readers is new for Aurora Serverless v2 compared to Aurora Serverless v1. You can add up to 15 Aurora Serverless v2 readers spread across 3 AZs to an Aurora DB cluster.

For business-critical applications that must remain available even in case of an issue that affects your entire cluster or the whole AWS Region, you can set up an Aurora global database. You can use Aurora Serverless v2 capacity in the secondary clusters so they're ready to take over during disaster recovery. They can also scale down when the database isn't busy. For details about Aurora global databases, see Using Amazon Aurora global databases.

Aurora Serverless v2 works like provisioned for failover and other high availability features. For more information, see High availability for Amazon Aurora.

Suppose that you want to ensure maximum availability for your Aurora Serverless v2 cluster. You can create a reader in addition to the writer. If you assign the reader to promotion tier 0 or 1, whatever scaling happens for the writer also happens for the reader. That way, a reader with identical capacity is always ready to take over for the writer in case of a failover.

Suppose that you want to run quarterly reports for your business at the same time as your cluster continues to process transactions. If you add an Aurora Serverless v2 reader to the cluster and assign it to a promotion tier from 2 through 15, you can connect directly to that reader to run the reports. Depending on how memory-intensive and CPU-intensive the reporting queries are, that reader can scale up to accommodate the workload. It can then scale down again when the reports are finished.

Aurora Serverless v2 and storage

The storage for each Aurora DB cluster consists of six copies of all your data, spread across three AZs. This built-in data replication applies regardless of whether your DB cluster includes any readers in addition to the writer. That way, your data is safe, even from issues that affect the compute capacity of the cluster.

Aurora Serverless v2 storage has the same reliability and durability characteristics as described in Amazon Aurora storage and reliability. That's because the storage for Aurora DB clusters works the same whether the compute capacity uses Aurora Serverless v2 or provisioned.

Configuration parameters for Aurora clusters

You can adjust all the same cluster and database configuration parameters for clusters with Aurora Serverless v2 capacity as for provisioned DB clusters. However, some capacity-related parameters are handled differently for Aurora Serverless v2. In a mixed-configuration cluster, the parameter values that you specify for those capacity-related parameters still apply to any provisioned writers and readers.

Almost all of the parameters work the same way for Aurora Serverless v2 writers and readers as for provisioned ones. The exceptions are some parameters that Aurora automatically adjusts during scaling, and some parameters that Aurora keeps at fixed values that depend on the maximum capacity setting.

For example, the amount of memory reserved for the buffer cache increases as a writer or reader scales up, and decreases as it scales down. That way, memory can be released when your database isn't busy. Conversely, Aurora automatically sets the maximum number of connections to a value that's appropriate based on the maximum capacity setting. That way, active connections aren't dropped if the load drops and Aurora Serverless v2 scales down. For information about how Aurora Serverless v2 handles specific parameters, see Working with parameter groups for Aurora Serverless v2.

Requirements and limitations for Aurora Serverless v2

When you create a cluster where you intend to use Aurora Serverless v2 DB instances, pay attention to the following requirements and limitations.

Topics

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and Aurora Serverless v2, see Supported Regions and Aurora DB engines for Aurora Serverless v2.

The following example shows the AWS CLI commands to confirm the exact DB engine values you can use with Aurora Serverless v2 for a specific AWS Region. The `--db-instance-class` parameter for Aurora Serverless v2 is always `db.serverless`. The `--engine` parameter can be `aurora-mysql` or `aurora-postgresql`. Substitute the appropriate `--region` and `--engine` values to confirm the `--engine-version` values that you can use. If the command doesn't produce any output, Aurora Serverless v2 isn't available for that combination of AWS Region and DB engine.

```
aws rds describe-orderable-db-instance-options --engine aurora-mysql --db-instance-
class db.serverless \
  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output
 text

aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-
instance-class db.serverless \
  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output
 text
```

Clusters that use Aurora Serverless v2 must have a capacity range specified

An Aurora cluster must have a `ServerlessV2ScalingConfiguration` attribute before you can add any DB instances that use the `db.serverless` DB instance class. This attribute specifies the capacity range. Aurora Serverless v2 capacity ranges from a minimum of 0.5 Aurora capacity units (ACU) through 128 ACUs, in increments of 0.5 ACU. Each ACU provides the equivalent of approximately 2 gibibytes (GiB) of RAM and associated CPU and networking. For details about how Aurora Serverless v2 uses the capacity range settings, see How Aurora Serverless v2 works.

You can specify the minimum and maximum ACU values in the AWS Management Console when you create a cluster and associated Aurora Serverless v2 DB instance. You can also specify the `--serverless-v2-scaling-configuration` option in the AWS CLI. Or you can specify the `ServerlessV2ScalingConfiguration` parameter with the Amazon RDS API. You can specify this attribute when you create a cluster or modify an existing cluster. For the procedures to set the capacity range, see Setting the Aurora Serverless v2 capacity range for a cluster. For a detailed discussion of how to pick minimum and maximum capacity values and how those settings affect some database parameters, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster.

Some provisioned features aren't supported in Aurora Serverless v2

The following features from Aurora provisioned DB instances currently aren't available for Amazon Aurora Serverless v2:

- Database activity streams (DAS).
- Cluster cache management for Aurora PostgreSQL. The `apg_ccm_enabled` configuration parameter doesn't apply to Aurora Serverless v2 DB instances.

Some Aurora features work with Aurora Serverless v2, but might cause issues if your capacity range is lower than needed for the memory requirements for those features with your specific workload. In that case, your database might not perform as well as usual, or might encounter out-of-memory errors. For recommendations about setting the appropriate capacity range, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster. For troubleshooting information if your database encounters out-of-memory errors due to a misconfigured capacity range, see Avoiding out-of-memory errors.

Aurora Auto Scaling isn't supported. This type of scaling adds new readers to handle additional read-intensive workload, based on CPU usage. However, scaling based on CPU usage isn't meaningful for Aurora Serverless v2. As an alternative, you can create Aurora Serverless v2 reader DB instances in advance and leave them scaled down to low capacity. That's a faster and less disruptive way to scale a cluster's read capacity than adding new DB instances dynamically.

Some Aurora Serverless v2 aspects are different from Aurora Serverless v1

If you are an Aurora Serverless v1 user and this is your first time using Aurora Serverless v2, consult the differences between Aurora Serverless v2 and Aurora Serverless v1 requirements to understand how requirements are different between Aurora Serverless v1 and Aurora Serverless v2.

Creating a DB cluster that uses Aurora Serverless v2

To create an Aurora cluster where you can add Aurora Serverless v2 DB instances, you follow the same procedure as in Creating an Amazon Aurora DB cluster. With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. You can have clusters where some DB instances use Aurora Serverless v2 and some DB instances are provisioned.

Topics

Settings for Aurora Serverless v2 DB clusters

Make sure that the cluster's initial settings meet the requirements listed in Requirements and limitations for Aurora Serverless v2. Specify the following settings to make sure that you can add Aurora Serverless v2 DB instances to the cluster:

AWS Region

Create the cluster in an AWS Region where Aurora Serverless v2 DB instances are available. For details about available Regions, see Supported Regions and Aurora DB engines for Aurora Serverless v2.

DB engine version

Choose an engine version that's compatible with Aurora Serverless v2. For information about the Aurora Serverless v2 version requirements, see Requirements and limitations for Aurora Serverless v2.

DB instance class

If you create a cluster using the AWS Management Console, you choose the DB instance class for the writer DB instance at the same time. Choose the **Serverless** DB instance class. When you choose that DB instance class, you also specify the capacity range for the writer DB instance. That same capacity range applies to all other Aurora Serverless v2 DB instances that you add to that cluster.

If you don't see the **Serverless** choice for the DB instance class, make sure that you chose a DB engine version that's supported for Supported Regions and Aurora DB engines for Aurora Serverless v2.

When you use the AWS CLI or the Amazon RDS API, the parameter that you specify for the DB instance class is `db.serverless`.

Capacity range

> Fill in the minimum and maximum Aurora capacity unit (ACU) values that apply to all the DB instances in the cluster. This option is available on both the **Create cluster** and **Add reader** console pages when you choose **Serverless** for the DB instance class.
>
> If you don't see the minimum and maximum ACU fields, make sure that you chose the **Serverless** DB instance class for the writer DB instance.

If you initially create the cluster with a provisioned DB instance, you don't specify the minimum and maximum ACUs. In that case you can modify the cluster afterward to add that setting. You can also add an Aurora Serverless v2 reader DB instance to the cluster. You specify the capacity range as part of that process.

Until you specify the capacity range for your cluster, you can't add any Aurora Serverless v2 DB instances to the cluster using the AWS CLI or RDS API. If you try to add a Aurora Serverless v2 DB instance, you get an error. In the AWS CLI or the RDS API procedures, the capacity range is represented by the `ServerlessV2ScalingConfiguration` attribute.

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second or later reader DB instance to your cluster. For more information, see Choosing the promotion tier for an Aurora Serverless v2 reader.

Creating an Aurora Serverless v2 DB cluster

You can use the AWS Management Console, AWS CLI, or RDS API to create an Aurora Serverless v2 DB cluster.

Console

To create a cluster with an Aurora Serverless v2 writer

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**. On the page that appears, choose the following options:

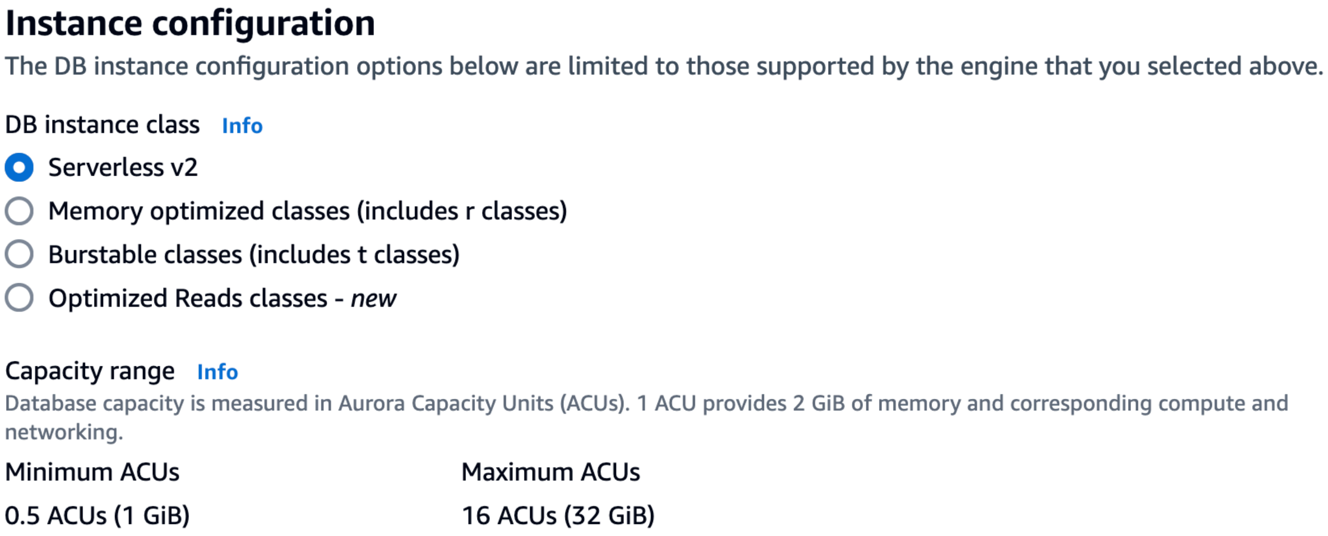
    - For **Engine type**, choose **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.

   - For **Version**, choose one of the supported versions for Supported Regions and Aurora DB engines for Aurora Serverless v2.

4. For **DB instance class**, select **Serverless v2**.

5. For **Capacity range**, you can accept the default range. Or you can choose other values for minimum and maximum capacity units. You can choose from 0.5 ACUs minimum through 128 ACUs maximum, in increments of 0.5 ACU.

   For more information about Aurora Serverless v2 capacity units, see Aurora Serverless v2 capacity and Performance and scaling for Aurora Serverless v2.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2
○ Memory optimized classes (includes r classes)
○ Burstable classes (includes t classes)
○ Optimized Reads classes - *new*

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

6. Choose any other DB cluster settings, as described in Settings for Aurora DB clusters.

7. Choose **Create database** to create your Aurora DB cluster with an Aurora Serverless v2 DB instance as the writer instance, also known as the primary DB instance.

CLI

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the AWS CLI, you follow the CLI procedure in Creating an Amazon Aurora DB cluster. Include the following parameters in your `create-db-cluster` command:

- --region *AWS_Region_where_Aurora Serverless v2_instances_are_available*
- --engine-version *serverless_v2_compatible_engine_version*
- --serverless-v2-scaling-configuration MinCapacity=*minimum_capacity*,MaxCapacity=*maximum_capacity*

The following example shows the creation of an Aurora Serverless v2 DB cluster.

```
aws rds create-db-cluster \
    --db-cluster-identifier my-serverless-v2-cluster \
    --region eu-central-1 \
    --engine aurora-mysql \
    --engine-version 8.0.mysql_aurora.3.04.1 \
    --serverless-v2-scaling-configuration MinCapacity=1,MaxCapacity=4 \
    --master-username myuser \
    --manage-master-user-password
```

Note

When you create an Aurora Serverless v2 DB cluster using the AWS CLI, the engine mode appears in the output as `provisioned` rather than `serverless`. The `serverless` engine mode refers to Aurora Serverless v1.

This example specifies the `--manage-master-user-password` option to generate the administrative password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager. Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For information about the Aurora Serverless v2 version requirements, see Requirements and limitations for Aurora Serverless v2. For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora Serverless v2 capacity and Performance and scaling for Aurora Serverless v2.

To verify whether an existing cluster has the capacity settings specified, check the output of the `describe-db-clusters` command for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
    "MinCapacity": 1.5,
    "MaxCapacity": 24.0
}
```

> **Tip**
>
> If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `modify-db-cluster` command afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

API

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the RDS API, you follow the API procedure in Creating an Amazon Aurora DB cluster. Choose the following settings. Make sure that your `CreateDBCluster` operation includes the following parameters:

```
EngineVersion serverless_v2_compatible_engine_version
ServerlessV2ScalingConfiguration with MinCapacity=minimum_capacity and
 MaxCapacity=maximum_capacity
```

For information about the Aurora Serverless v2 version requirements, see Requirements and limitations for Aurora Serverless v2. For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora Serverless v2 capacity and Performance and scaling for Aurora Serverless v2.

To check if an existing cluster has the capacity settings specified, check the output of the `DescribeDBClusters` operation for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
    "MinCapacity": 1.5,
    "MaxCapacity": 24.0
}
```

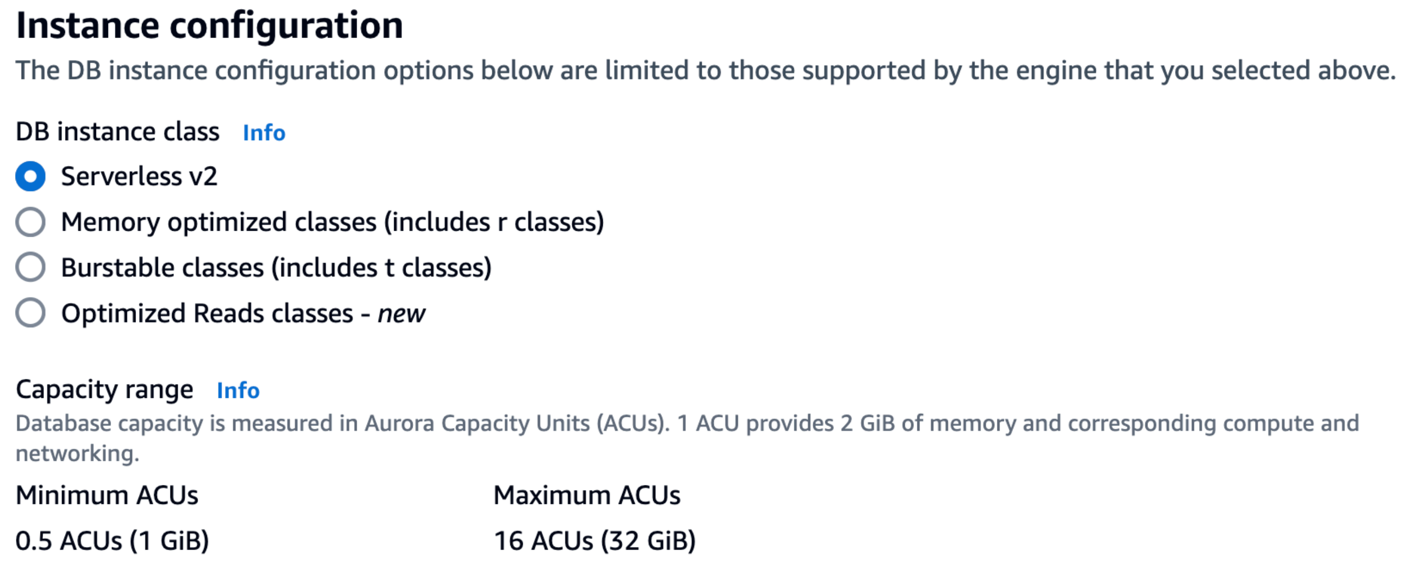
> **Tip**
>
> If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `ModifyDBCluster` operation afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

Creating an Aurora Serverless v2 writer DB instance

Console

When you create a DB cluster using the AWS Management Console, you specify the properties of the writer DB instance at the same time. To make the writer DB instance use Aurora Serverless v2, choose the **Serverless** DB instance class.

Then you set the capacity range for the cluster by specifying the minimum and maximum Aurora capacity unit (ACU) values. These minimum and maximum values apply to each Aurora Serverless v2 DB instance in the cluster.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2
○ Memory optimized classes (includes r classes)
○ Burstable classes (includes t classes)
○ Optimized Reads classes - *new*

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

If you don't create an Aurora Serverless v2 DB instance when you first create the cluster, you can add one or more Aurora Serverless v2 DB instances later. To do so, follow the procedures in Adding an Aurora Serverless v2 reader and Converting a provisioned writer or reader to Aurora Serverless v2. You specify the capacity range at the time that you add the first Aurora Serverless v2 DB instance to the cluster. You can change the capacity range later by following the procedure in Setting the Aurora Serverless v2 capacity range for a cluster.

CLI

When you create a Aurora Serverless v2 DB cluster using the AWS CLI, you explicitly add the writer DB instance using the create-db-instance command. Include the following parameter:

- `--db-instance-class db.serverless`

The following example shows the creation of an Aurora Serverless v2 writer DB instance.

```
aws rds create-db-instance \
    --db-cluster-identifier my-serverless-v2-cluster \
    --db-instance-identifier my-serverless-v2-instance \
    --db-instance-class db.serverless \
    --engine aurora-mysql
```

Managing Aurora Serverless v2 DB clusters

With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. The Aurora Serverless v2 properties apply to one or more DB instances within a cluster. Thus, the procedures for creating clusters, modifying clusters, creating and restoring snapshots, and so on, are basically the same as for other kinds of Aurora clusters. For general procedures for managing Aurora clusters and DB instances, see Managing an Amazon Aurora DB cluster.

In the following topics, you can learn about management considerations for clusters that contain Aurora Serverless v2 DB instances.

Topics

Setting the Aurora Serverless v2 capacity range for a cluster

To modify configuration parameters or other settings for clusters containing Aurora Serverless v2 DB instances, or the DB instances themselves, follow the same general procedures as for provisioned clusters. For details, see Modifying an Amazon Aurora DB cluster.

The most important setting that's unique to Aurora Serverless v2 is the capacity range. After you set the minimum and maximum Aurora capacity unit (ACU) values for an Aurora cluster, you don't need to actively adjust the capacity of the Aurora Serverless v2 DB instances in the cluster. Aurora does that for you. This setting is managed at the cluster level. The same minimum and maximum ACU values apply to each Aurora Serverless v2 DB instance in the cluster.

You can set the following specific values:

- **Minimum ACUs** – The Aurora Serverless v2 DB instance can reduce capacity down to this number of ACUs.
- **Maximum ACUs** – The Aurora Serverless v2 DB instance can increase capacity up to this number of ACUs.

> **Note**
>
> When you modify the capacity range for an Aurora Serverless v2 DB cluster, the change takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

For details about the effects of the capacity range and how to monitor and fine-tune it, see Important Amazon CloudWatch metrics for Aurora Serverless v2 and Performance and scaling for Aurora Serverless v2. Your goal is to make sure that the maximum capacity for the cluster is high enough to handle spikes in workload, and the minimum is low enough to minimize costs when the cluster isn't busy.

Suppose that you determine based on your monitoring that the ACU range for the cluster should be higher, lower, wider, or narrower. You can set the capacity of an Aurora cluster to a specific range of ACUs with the AWS Management Console, the AWS CLI, or the Amazon RDS API. This capacity range applies to every Aurora Serverless v2 DB instance in the cluster.

For example, suppose that your cluster has a capacity range of 1–16 ACUs and contains two Aurora Serverless v2 DB instances. Then the cluster as a whole consumes somewhere between 2 ACUs (when idle) and 32 ACUs (when fully utilized). If you change the capacity range from 8 to 20.5 ACUs, now the cluster consumes 16 ACUs when idle, and up to 41 ACUs when fully utilized.

Aurora automatically sets certain parameters for Aurora Serverless v2 DB instances to values that depend on the maximum ACU value in the capacity range. For the list of such parameters, see

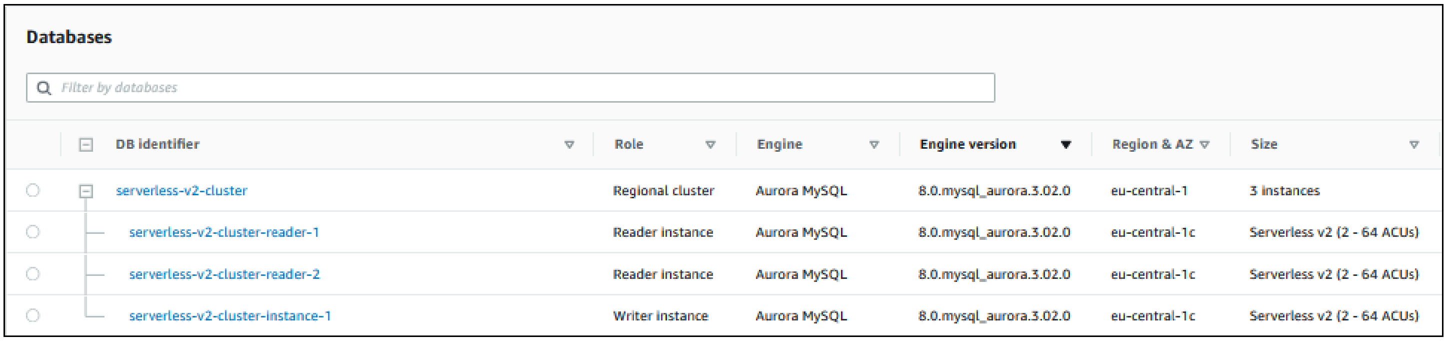
Maximum connections for Aurora Serverless v2. For static parameters that rely on this type of calculation, the value is evaluated again when you reboot the DB instance. Thus, you can update the value of such parameters by rebooting the DB instance after changing the capacity range. To check whether you need to reboot your DB instance to pick up such parameter changes, check the `ParameterApplyStatus` attribute of the DB instance. A value of `pending-reboot` indicates that rebooting will apply changes to some parameter values.

Console

You can set the capacity range of a cluster that contains Aurora Serverless v2 DB instances with the AWS Management Console.

When you use the console, you set the capacity range for the cluster at the time that you add the first Aurora Serverless v2 DB instance to that cluster. You might do so when you choose the **Serverless v2** DB instance class for the writer DB instance when you create the cluster. Or you might do so when you choose the **Serverless** DB instance class when you add an Aurora Serverless v2 reader DB instance to the cluster. Or you might do so when you convert an existing provisioned DB instance in the cluster to the **Serverless** DB instance class. For the full versions of those procedures, see Creating an Aurora Serverless v2 writer DB instance, Adding an Aurora Serverless v2 reader, and Converting a provisioned writer or reader to Aurora Serverless v2.

Whatever capacity range that you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 reader DB instances. Each has an identical capacity range of 2–64 ACUs.



Databases

DB identifier	Role	Engine	Engine version	Region & AZ	Size
serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	3 instances
serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)
serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)
serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)

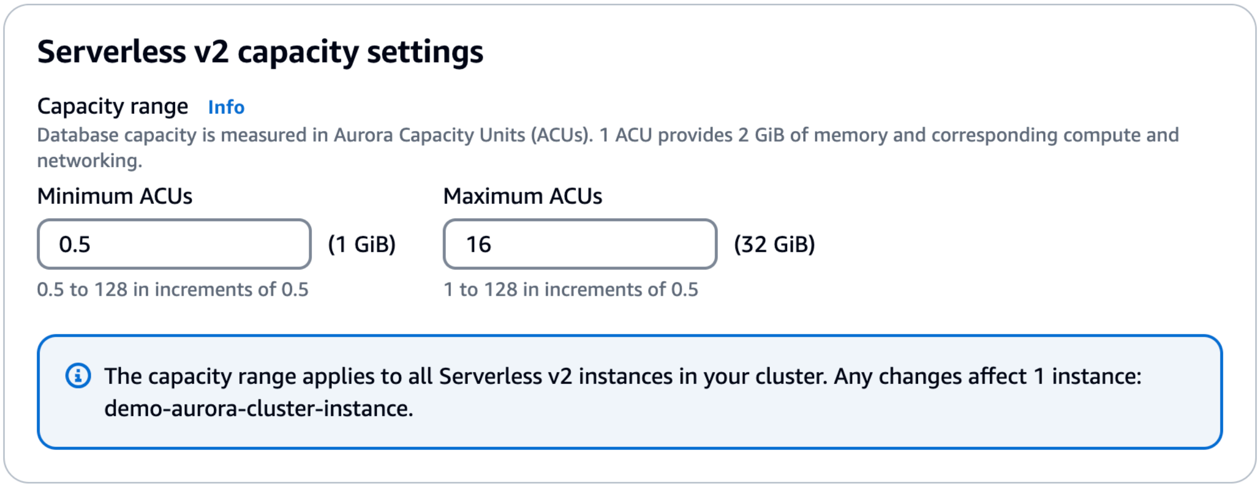
To modify the capacity range of an Aurora Serverless v2 cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

3. Choose the cluster containing your Aurora Serverless v2 DB instances from the list. The cluster must already contain at least one Aurora Serverless v2 DB instance. Otherwise, Aurora doesn't show the **Capacity range** section.
4. For **Actions**, choose **Modify**.
5. In the **Capacity range** section, choose the following:

   a. Enter a value for **Minimum ACUs**. The console shows the allowed range of values. You can choose a minimum capacity from 0.5 to 128 ACUs. You can choose a maximum capacity from 1 to 128 ACUs. You can adjust the capacity values in increments of 0.5 ACU.

   b. Enter a value for **Maximum ACUs**. This value must be greater than or equal to **Minimum ACUs**. The console shows the allowed range of values. The following figure shows that choice.



Serverless v2 capacity settings

Capacity range Info
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs: 0.5 (1 GiB)
0.5 to 128 in increments of 0.5

Maximum ACUs: 16 (32 GiB)
1 to 128 in increments of 0.5

The capacity range applies to all Serverless v2 instances in your cluster. Any changes affect 1 instance: demo-aurora-cluster-instance.

6. Choose **Continue**. The **Summary of modifications** page appears.
7. Choose **Apply immediately**.

   The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.
8. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

AWS CLI

To set the capacity of a cluster where you intend to use Aurora Serverless v2 DB instances using the AWS CLI, run the modify-db-cluster AWS CLI command. Specify the `--serverless-v2-scaling-configuration` option. The cluster might already contain one or more

Aurora Serverless v2 DB instances, or you can add the DB instances later. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- `0.5`, 1, `1.5`, 2, and so on, in steps of 0.5, up to a maximum of 128.

In this example, you set the ACU range of an Aurora DB cluster named `sample-cluster` to a minimum of `48.5` and a maximum of 64.

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--serverless-v2-scaling-configuration MinCapacity=48.5,MaxCapacity=64
```

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

After doing so, you can add Aurora Serverless v2 DB instances to the cluster and each new DB instance can scale between 48.5 and 64 ACUs. The new capacity range also applies to any Aurora Serverless v2 DB instances that were already in the cluster. The DB instances scale up or down if necessary to fall within the new capacity range.

For additional examples of setting the capacity range using the CLI, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster.

To modify the scaling configuration of an Aurora Serverless DB cluster using the AWS CLI, run the modify-db-cluster AWS CLI command. Specify the `--serverless-v2-scaling-configuration` option to configure the minimum capacity and maximum capacity. Valid capacity values include the following:

- Aurora MySQL: `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of `128`.
- Aurora PostgreSQL: `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of `128`.

In the following example, you modify the scaling configuration of an Aurora Serverless v2 DB instance named `sample-instance` that's part of a cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster ^
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

RDS API

You can set the capacity of an Aurora DB instance with the ModifyDBCluster API operation. Specify the `ServerlessV2ScalingConfiguration` parameter. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- `0.5`, 1, `1.5`, 2, and so on, in steps of 0.5, up to a maximum of 128.

You can modify the scaling configuration of a cluster containing Aurora Serverless v2 DB instances with the ModifyDBCluster API operation. Specify the `ServerlessV2ScalingConfiguration` parameter to configure the minimum capacity and the maximum capacity. Valid capacity values include the following:

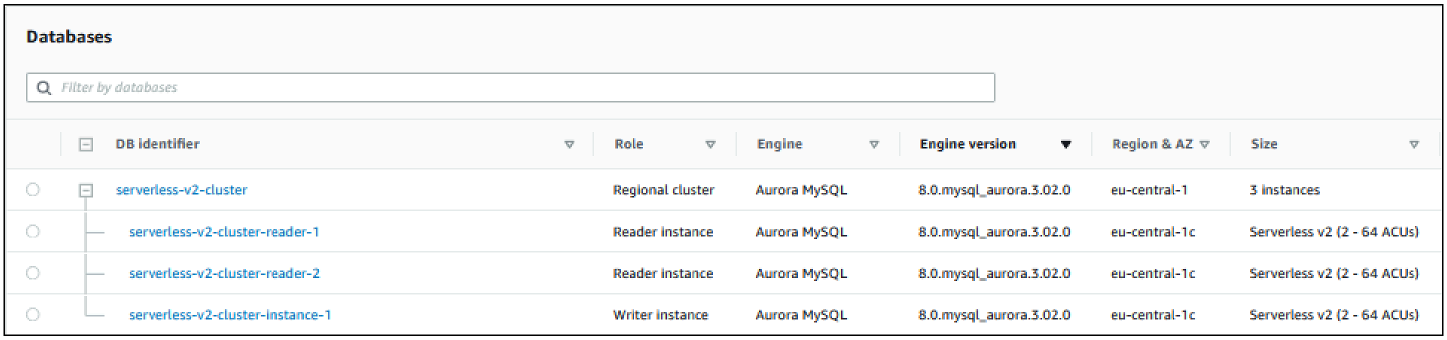
- Aurora MySQL: `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of `128`.
- Aurora PostgreSQL: `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of `128`.

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

Checking the capacity range for Aurora Serverless v2

The procedure to check the capacity range for your Aurora Serverless v2 cluster requires that you first set a capacity range. If you haven't done so, follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster.

Whatever capacity range you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 DB instances. Each has an identical capacity range.

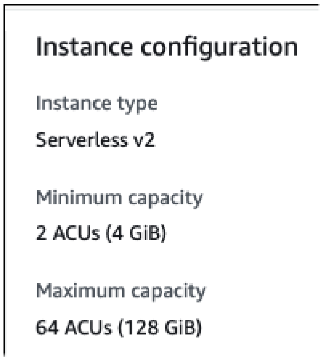


Databases

Filter by databases

DB identifier	Role	Engine	Engine version	Region & AZ	Size
serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	3 instances
serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)
serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)
serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)

You can also view the details page for any Aurora Serverless v2 DB instance in the cluster. DB instances' capacity range appears on the **Configuration** tab.



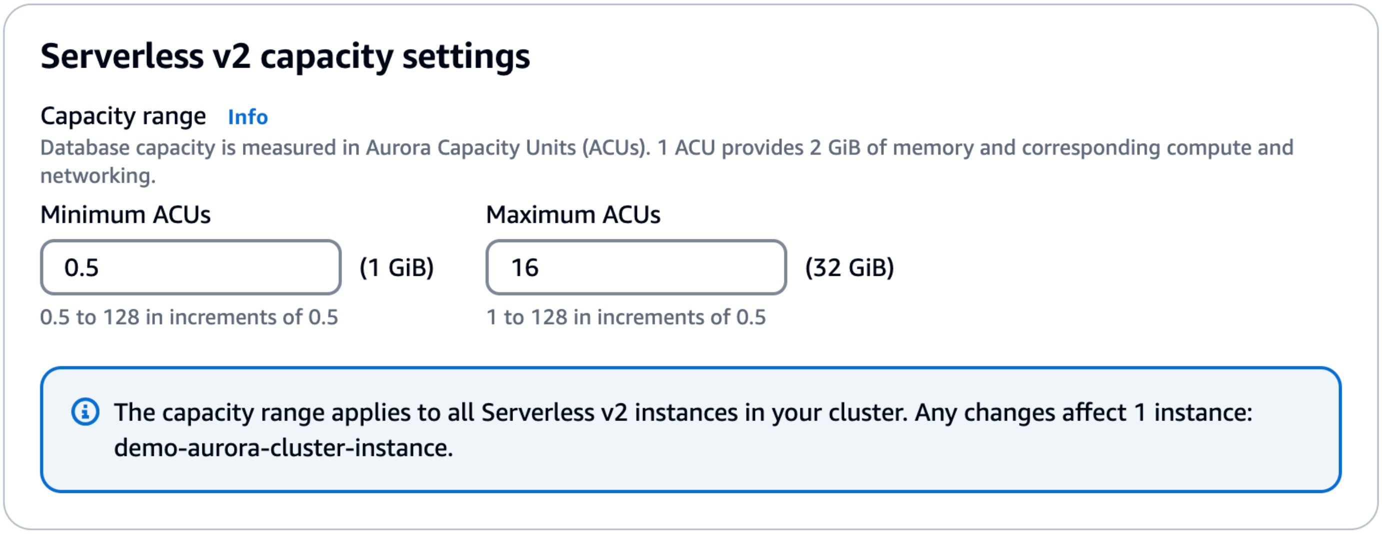
Instance configuration

Instance type
Serverless v2

Minimum capacity
2 ACUs (4 GiB)

Maximum capacity
64 ACUs (128 GiB)

You can also see the current capacity range for the cluster on the **Modify** page for the cluster. The following image shows how. At that point, you can change the capacity range. For all the ways that you can set or change the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster](#).



Serverless v2 capacity settings

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs: 0.5 (1 GiB)
0.5 to 128 in increments of 0.5

Maximum ACUs: 16 (32 GiB)
1 to 128 in increments of 0.5

The capacity range applies to all Serverless v2 instances in your cluster. Any changes affect 1 instance: demo-aurora-cluster-instance.

Checking the current capacity range for an Aurora cluster

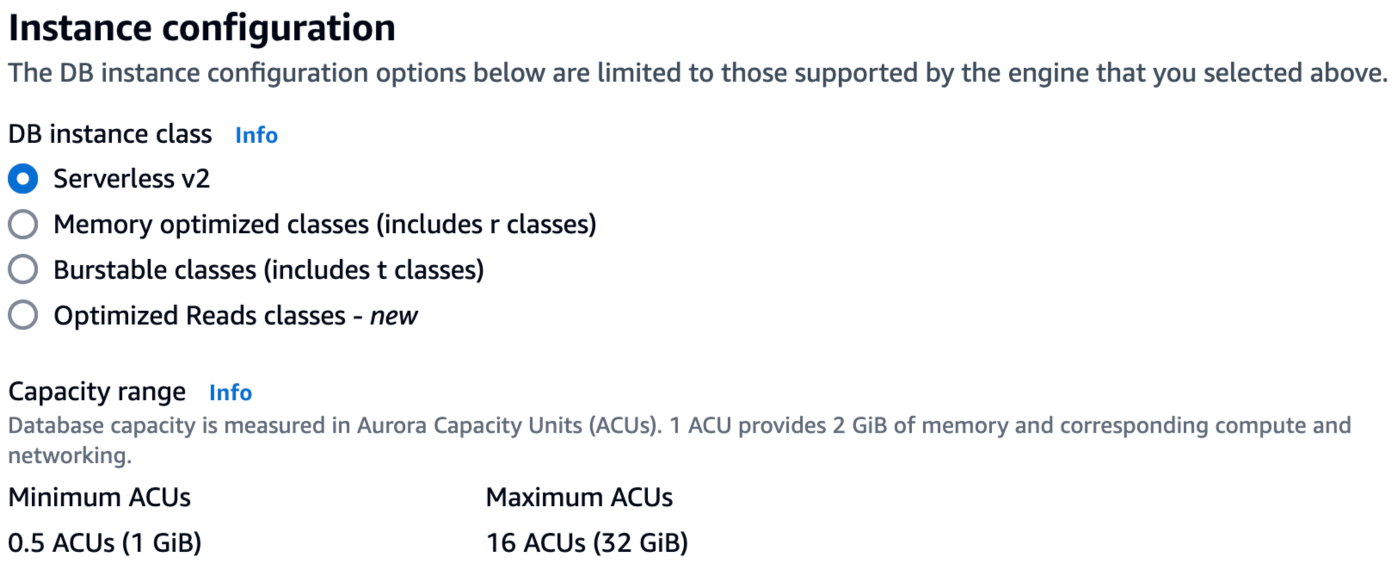
You can check the capacity range that's configured for Aurora Serverless v2 DB instances in a cluster by examining the `ServerlessV2ScalingConfiguration` attribute for the cluster. The following AWS CLI example shows a cluster with a minimum capacity of 0.5 Aurora capacity units (ACUs) and a maximum capacity of 16 ACUs.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-64-acu-cluster \
  --query 'DBClusters[*].[ServerlessV2ScalingConfiguration]'
[
    [
        {
            "MinCapacity": 0.5,
            "MaxCapacity": 16.0
        }
    ]
]
```

Adding an Aurora Serverless v2 reader

To add an Aurora Serverless v2 reader DB instance to your cluster, you follow the same general procedure as in [Adding Aurora Replicas to a DB cluster](). Choose the **Serverless v2** instance class for the new DB instance.

If the reader DB instance is the first Aurora Serverless v2 DB instance in the cluster, you also choose the capacity range. The following image shows the controls that you use to specify the minimum and maximum Aurora capacity units (ACUs). This setting applies to this reader DB instance and to any other Aurora Serverless v2 DB instances that you add to the cluster. Each Aurora Serverless v2 DB instance can scale between the minimum and maximum ACU values.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

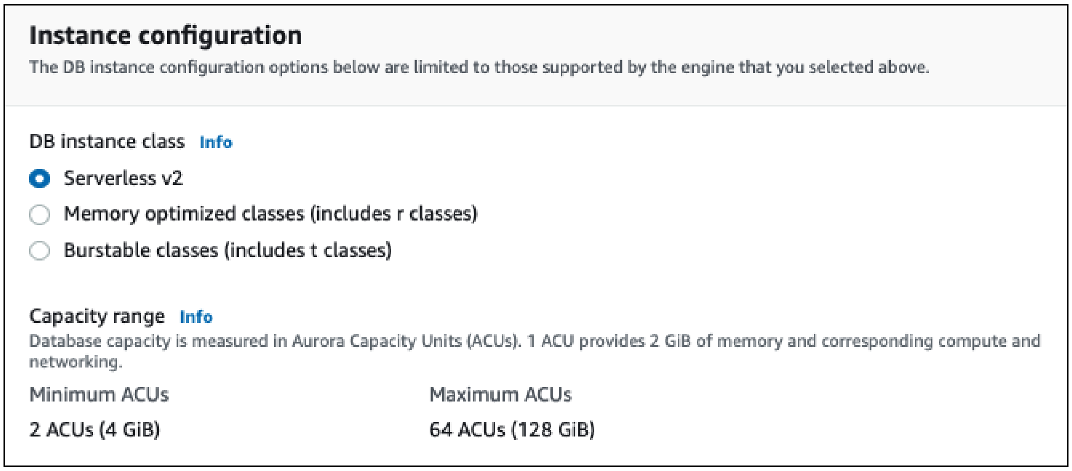
○ Optimized Reads classes - *new*

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

If you already added any Aurora Serverless v2 DB instances to the cluster, adding another Aurora Serverless v2 reader DB instance shows you the current capacity range. The following image shows those read-only controls.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
2 ACUs (4 GiB)	64 ACUs (128 GiB)

If you want to change the capacity range for the cluster, follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster.

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second reader or later DB instance to your cluster. For more information, see Choosing the promotion tier for an Aurora Serverless v2 reader.

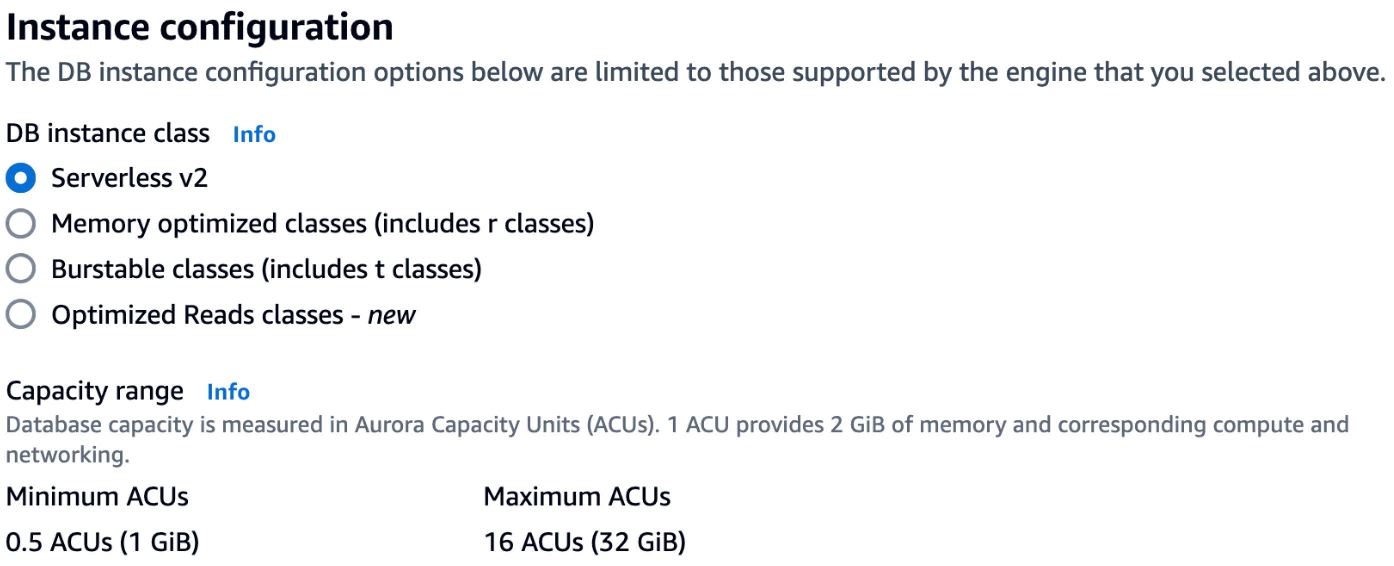
For other ways that you can see the current capacity range for a cluster, see Checking the capacity range for Aurora Serverless v2.

Converting a provisioned writer or reader to Aurora Serverless v2

You can convert a provisioned DB instance to use Aurora Serverless v2. To do so, you follow the procedure in Modifying a DB instance in a DB cluster. The cluster must meet the requirements in Requirements and limitations for Aurora Serverless v2. For example, Aurora Serverless v2 DB instances require that the cluster be running certain minimum engine versions.

Suppose that you are converting a running provisioned cluster to take advantage of Aurora Serverless v2. In that case, you can minimize downtime by converting a DB instance to Aurora Serverless v2 as the first step in the switchover process. For the full procedure, see Switching from a provisioned cluster to Aurora Serverless v2.

If the DB instance that you convert is the first Aurora Serverless v2 DB instance in the cluster, you choose the capacity range for the cluster as part of the **Modify** operation. This capacity range applies to each Aurora Serverless v2 DB instance that you add to the cluster. The following image shows the page where you specify the minimum and maximum Aurora capacity units (ACUs).



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

○ Optimized Reads classes - *new*

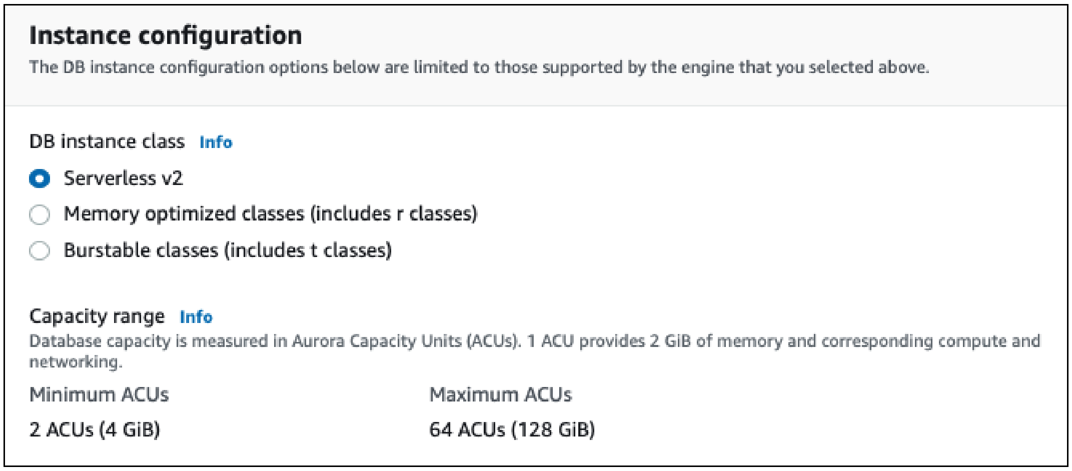
Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

For details about the significance of the capacity range, see Aurora Serverless v2 capacity.

If the cluster already contains one or more Aurora Serverless v2 DB instances, you see the existing capacity range during the **Modify** operation. The following image shows an example of that information panel.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless v2

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
2 ACUs (4 GiB)	64 ACUs (128 GiB)

If you want to change the capacity range for the cluster after you add more Aurora Serverless v2 DB instances, follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster.

Converting an Aurora Serverless v2 writer or reader to provisioned

You can convert an Aurora Serverless v2 DB instance to a provisioned DB instance. To do so, you follow the procedure in Modifying a DB instance in a DB cluster. Choose a DB instance class other than **Serverless**.

You might convert an Aurora Serverless v2 DB instance to provisioned if it needs a larger capacity than is available with the maximum Aurora capacity units (ACUs) of an Aurora Serverless v2 DB instance. For example, the largest db.r5 and db.r6g DB instance classes have a larger memory capacity than an Aurora Serverless v2 DB instance can scale to.

> **Tip**
>
> Some of the older DB instance classes such as db.r3 and db.t2 aren't available for the Aurora versions that you use with Aurora Serverless v2. To see which DB instance classes you can use when converting an Aurora Serverless v2 DB instance to a provisioned one, see Supported DB engines for DB instance classes.

If you are converting the writer DB instance of your cluster from Aurora Serverless v2 to provisioned, you can follow the procedure in Switching from a provisioned cluster to Aurora Serverless v2 but in reverse. Switch one of the reader DB instances in the cluster from Aurora Serverless v2 to provisioned. Then perform a failover to make that provisioned DB instance into the writer.

Any capacity range that you previously specified for the cluster remains in place, even if all Aurora Serverless v2 DB instances are removed from the cluster. If you want to change the capacity range, you can modify the cluster, as explained in Setting the Aurora Serverless v2 capacity range for a cluster.

Choosing the promotion tier for an Aurora Serverless v2 reader

For clusters containing multiple Aurora Serverless v2 DB instances or a mixture of provisioned and Aurora Serverless v2 DB instances, pay attention to the promotion tier setting for each Aurora Serverless v2 DB instance. This setting controls more behavior for Aurora Serverless v2 DB instances than for provisioned DB instances.

In the AWS Management Console, you specify this setting using the **Failover priority** choice under **Additional configuration** for the **Create database**, **Modify instance**, and **Add reader** pages. You see this property for existing DB instances in the optional **Priority tier** column on the **Databases** page. You can also see this property on the details page for a DB cluster or DB instance.

For provisioned DB instances, the choice of tier 0–15 determines only the order in which Aurora chooses which reader DB instance to promote to the writer during a failover operation. For Aurora Serverless v2 reader DB instances, the tier number also determines whether the DB instance scales up to match the capacity of the writer DB instance or scales independently based on its own workload. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. That way, they are ready to take over from the writer DB instance in case of a failover. If the writer DB instance is a provisioned DB instance, Aurora estimates the equivalent Aurora Serverless v2 capacity. It uses that estimate as the minimum capacity for the Aurora Serverless v2 reader DB instance.

Aurora Serverless v2 reader DB instances in tiers 2–15 don't have the same constraint on their minimum capacity. When they are idle, they can scale down to the minimum Aurora capacity unit (ACU) value specified in the cluster's capacity range.

The following Linux AWS CLI example shows how to examine the promotion tiers of all the DB instances in your cluster. The final field includes a value of `True` for the writer DB instance and `False` for all the reader DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier promotion-tier-demo \
  --query 'DBClusters[*].DBClusterMembers[*].
[PromotionTier,DBInstanceIdentifier,IsClusterWriter]' \
  --output text
```

```
1   instance-192  True
1   tier-01-4840  False
10  tier-10-7425  False
15  tier-15-6694  False
```

The following Linux AWS CLI example shows how to change the promotion tier of a specific DB instance in your cluster. The commands first modify the DB instance with a new promotion tier. Then they wait for the DB instance to become available again and confirm the new promotion tier for the DB instance.

```
$ aws rds modify-db-instance --db-instance-identifier instance-192 --promotion-tier 0
$ aws rds wait db-instance-available --db-instance-identifier instance-192
$ aws rds describe-db-instances --db-instance-identifier instance-192 \
  --query '*[].[PromotionTier]' --output text
0
```

For more guidance about specifying promotion tiers for different use cases, see Aurora Serverless v2 scaling.

Using TLS/SSL with Aurora Serverless v2

Aurora Serverless v2 can use the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v2 DB instances. It supports TLS/SSL versions 1.0, 1.1, and 1.2. For general information about using TLS/SSL with Aurora, see Using TLS with Aurora MySQL DB clusters.

To learn more about connecting to Aurora MySQL database with the MySQL client, see Connecting to a DB instance running the MySQL database engine.

Aurora Serverless v2 supports all TLS/SSL modes available to the MySQL client (`mysql`) and PostgreSQL client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	mysql	psql
Connect without using TLS/SSL.	DISABLED	disable

Description of TLS/SSL mode	mysql	psql
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the certificate authority (CA).	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v2 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the Amazon root CA 1 trust store from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL client, do the following.

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem
 dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres client, see Connecting to a DB instance running the PostgreSQL database engine.

For more information about connecting to Aurora DB clusters in general, see Connecting to an Amazon Aurora DB cluster.

Supported cipher suites for connections to Aurora Serverless v2 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v2 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora MySQL DB clusters.

Aurora Serverless v2 DB clusters that are based on Aurora PostgreSQL support the same cipher suites as Aurora PostgreSQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora PostgreSQL DB clusters.

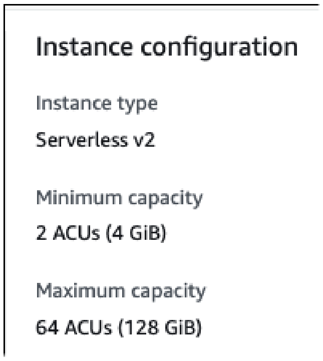
Viewing Aurora Serverless v2 writers and readers

You can view the details of Aurora Serverless v2 DB instances in the same way that you do for provisioned DB instances. To do so, follow the general procedure from Viewing an Amazon Aurora DB cluster. A cluster might contain all Aurora Serverless v2 DB instances, all provisioned DB instances, or some of each.

After you create one or more Aurora Serverless v2 DB instances, you can view which DB instances are type **Serverless** and which are type **Instance**. You can also view the minimum and maximum Aurora capacity units (ACUs) that the Aurora Serverless v2 DB instance can use. Each ACU is a combination of processing (CPU) and memory (RAM) capacity. This capacity range applies to each Aurora Serverless v2 DB instance in the cluster. For the procedure to check the capacity range of a cluster or any Aurora Serverless v2 DB instance in the cluster, see Checking the capacity range for Aurora Serverless v2.

In the AWS Management Console, Aurora Serverless v2 DB instances are marked under the **Size** column in the **Databases** page. Provisioned DB instances show the name of a DB instance class such as r6g.xlarge. The Aurora Serverless DB instances show **Serverless** for the DB instance class, along with the DB instance's minimum and maximum capacity. For example, you might see **Serverless v2 (4–64 ACUs)** or **Serverless v2 (1–40 ACUs)**.

You can find the same information on the **Configuration** tab for each Aurora Serverless v2 DB instance in the console. For example, you might see an **Instance type** section such as the following. Here, the **Instance type** value is **Serverless v2**, the **Minimum capacity** value is **2 ACUs (4 GiB)**, and the **Maximum capacity** value is **64 ACUs (128 GiB)**.



Instance configuration

Instance type
Serverless v2

Minimum capacity
2 ACUs (4 GiB)

Maximum capacity
64 ACUs (128 GiB)

You can monitor the capacity of each Aurora Serverless v2 DB instance over time. That way, you can check the minimum, maximum, and average ACUs consumed by each DB instance. You can also check how close the DB instance came to its minimum or maximum capacity. To see such details in the AWS Management Console, examine the graphs of Amazon CloudWatch metrics on the **Monitoring** tab for the DB instance. For information about the metrics to watch and how to interpret them, see Important Amazon CloudWatch metrics for Aurora Serverless v2.

Logging for Aurora Serverless v2

To turn on database logging, you specify the logs to enable using configuration parameters in your custom parameter group.

For Aurora MySQL, you can enable the following logs.

Aurora MySQL	Description
`general_log`	Creates the general log. Set to 1 to turn on. Default is off (0).
`log_queries_not_using_indexes`	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
`long_query_time`	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).
`server_audit_events`	The list of events to capture in the logs. Supported values are `CONNECT`, `QUERY`,

Aurora MySQL	Description
	QUERY_DCL , QUERY_DDL , QUERY_DML , and TABLE.
server_audit_logging	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v2 DB instances.

Aurora PostgreSQL	Description
log_connections	Logs each successful connection.
log_disconnections	Logs end of a session including duration.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).

Aurora PostgreSQL	Description
`log_statement`	Controls the specific SQL statements that get logged. Supported values are `none`, `ddl`, `mod`, and `all`. Default is `none`.

Topics

- Monitoring capacity with Amazon CloudWatch

Logging with Amazon CloudWatch

After you use the procedure in Logging for Aurora Serverless v2 to choose which database logs to turn on, you can choose which logs to upload ("publish") to Amazon CloudWatch.

You can use Amazon CloudWatch to analyze log data, create alarms, and view metrics. By default, error logs for Aurora Serverless v2 are enabled and automatically uploaded to CloudWatch. You can also upload other logs from Aurora Serverless v2 DB instances to CloudWatch.

Then you choose which of those logs to upload to CloudWatch, by using the **Log exports** settings in the AWS Management Console or the `--enable-cloudwatch-logs-exports` option in the AWS CLI.

You can choose which of your Aurora Serverless v2 logs to upload to CloudWatch. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. We recommend that you create your custom DB cluster parameter group before creating your Aurora Serverless v2 DB cluster, so that it's available to choose when you create a database on the console.

Note

For Aurora Serverless v2, you can create both DB cluster and DB parameter groups. This contrasts with Aurora Serverless v1, where you can only create DB cluster parameter groups.

Viewing Aurora Serverless v2 logs in Amazon CloudWatch

After you use the procedure in Logging with Amazon CloudWatch to choose which database logs to turn on, you can view the contents of the logs.

For more information on using CloudWatch with Aurora MySQL and Aurora PostgreSQL logs, see Monitoring log events in Amazon CloudWatch and Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.

To view logs for your Aurora Serverless v2 DB cluster

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose your AWS Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v2 DB cluster log from the list. The log naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/log_type
```

Note

For Aurora MySQL–compatible Aurora Serverless v2 DB clusters, the error log includes buffer pool scaling events even when there are no errors.

Monitoring capacity with Amazon CloudWatch

With Aurora Serverless v2, you can use CloudWatch to to monitor the capacity and utilization of all the Aurora Serverless v2 DB instances in your cluster. You can view instance-level metrics to check the capacity of each Aurora Serverless v2 DB instance as it scales up and down. You can also compare the capacity-related metrics to other metrics to see how changes in workloads affect resource consumption. For example, you can compare `ServerlessDatabaseCapacity` to `DatabaseUsedMemory`, `DatabaseConnections`, and `DMLThroughput` to assess how your DB cluster is responding during operations. For details about the capacity-related metrics that apply to Aurora Serverless v2, see Important Amazon CloudWatch metrics for Aurora Serverless v2.

To monitor your Aurora Serverless v2 DB cluster's capacity

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**. All available metrics appear as cards in the console, grouped by service name.
3. Choose **RDS**.
4. (Optional) Use the **Search** box to find the metrics that are especially important for Aurora Serverless v2: `ServerlessDatabaseCapacity`, `ACUUtilization`, `CPUUtilization`, and `FreeableMemory`.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora Serverless v2 DB cluster capacity using the capacity-related metrics. To learn how, see Building dashboards with CloudWatch.

To learn more about using Amazon CloudWatch with Amazon Aurora, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs.

Performance and scaling for Aurora Serverless v2

The following procedures and examples show how you can set the capacity range for Aurora Serverless v2 clusters and their associated DB instances. You can also use procedures following to monitor how busy your DB instances are. Then you can use your findings to determine if you need to adjust the capacity range upward or downward.

Before you use these procedures, make sure that you are familiar with how Aurora Serverless v2 scaling works. The scaling mechanism is different than in Aurora Serverless v1. For details, see Aurora Serverless v2 scaling.

Contents

Choosing the Aurora Serverless v2 capacity range for an Aurora cluster

With Aurora Serverless v2 DB instances, you set the capacity range that applies to all the DB instances in your DB cluster at the same time that you add the first Aurora Serverless v2 DB instance to the DB cluster. For the procedure to do so, see Setting the Aurora Serverless v2 capacity range for a cluster.

You can also change the capacity range for an existing cluster. The following sections discuss in more detail how to choose appropriate minimum and maximum values and what happens when you make a change to the capacity range. For example, changing the capacity range can modify the default values of some configuration parameters. Applying all the parameter changes can require rebooting each Aurora Serverless v2 DB instance.

Topics

Choosing the minimum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose 0.5 for the minimum Aurora Serverless v2 capacity setting. That value allows the DB instance to scale down the most when it's completely idle. However, depending on how you use that cluster and the other settings that you configure, a different value might be the most effective. Consider the following factors when choosing the minimum capacity setting:

- The scaling rate for an Aurora Serverless v2 DB instance depends on its current capacity. The higher the current capacity, the faster it can scale up. If you need the DB instance to quickly scale up to a very high capacity, consider setting the minimum capacity to a value where the scaling rate meets your requirement.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to make a rough estimate of the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of low traffic, consult Hardware specifications for DB instance classes for Aurora.

  For example, suppose that you use the db.r6g.xlarge DB instance class when your cluster has a low workload. That DB instance class has 32 GiB of memory. Thus, you can specify a minimum Aurora capacity unit (ACU) setting of 16 to set up an Aurora Serverless v2 DB instance that can scale down to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat lower value to let the DB instance scale down further in case your db.r6g.xlarge DB instance was sometimes underutilized.
- If your application works most efficiently when the DB instances have a certain amount of data in the buffer cache, consider specifying a minimum ACU setting where the memory is large enough to hold the frequently accessed data. Otherwise, some data is evicted from the buffer cache when the Aurora Serverless v2 DB instances scale down to a lower memory size. Then when the DB instances scale back up, the information is read back into the buffer cache over time. If the amount of I/O to bring the data back into the buffer cache is substantial, it might be more effective to choose a higher minimum ACU value.
- If your Aurora Serverless v2 DB instances run most of the time at a particular capacity, consider specifying a minimum capacity setting that's lower than that baseline, but not too much lower. Aurora Serverless v2 DB instances can most effectively estimate how much and how fast to scale up when the current capacity isn't drastically lower than the required capacity.
- If your provisioned workload has memory requirements that are too high for small DB instance classes such as T3 or T4g, choose a minimum ACU setting that provides memory comparable to an R5 or R6g DB instance.

  In particular, we recommend the following minimum capacity for use with the specified features (these recommendations are subject to change):

  - Performance Insights – 2 ACUs
  - Aurora global databases – 8 ACUs (applies only to the primary AWS Region)

- In some cases, your cluster might contain Aurora Serverless v2 reader DB instances that scale independently from the writer. If so, choose a minimum capacity setting that's high enough that when the writer DB instance is busy with a write-intensive workload, the reader DB instances can apply the changes from the writer without falling behind. If you observe replica lag in readers that are in promotion tiers 2–15, consider increasing the minimum capacity setting for your cluster. For details on choosing whether reader DB instances scale along with the writer or independently, see Choosing the promotion tier for an Aurora Serverless v2 reader.
- If you have a DB cluster with Aurora Serverless v2 reader DB instances, the readers don't scale along with the writer DB instance when the promotion tier of the readers isn't 0 or 1. In that case, setting a low minimum capacity can result in excessive replication lag. That's because the readers might not have enough capacity to apply changes from the writer when the database is busy. We recommend that you set the minimum capacity to a value that represents a comparable amount of memory and CPU to the writer DB instance.
- The value of the `max_connections` parameter for Aurora Serverless v2DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

  If you intend to use the Aurora PostgreSQL cluster for a high-connection workload, consider using a minimum ACU setting of 1 or higher. For details about how Aurora Serverless v2 handles the `max_connections` configuration parameter, see Maximum connections for Aurora Serverless v2.
- The time it takes for an Aurora Serverless v2 DB instance to scale from its minimum capacity to its maximum capacity depends on the difference between its minimum and maximum ACU values. When the current capacity of the DB instance is large, Aurora Serverless v2 scales up in larger increments than when the DB instance starts from a small capacity. Thus, if you specify a relatively large maximum capacity and the DB instance spends most of its time near that capacity, consider increasing the minimum ACU setting. That way, an idle DB instance can scale back up to maximum capacity more quickly.

Choosing the maximum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose some high value for the maximum Aurora Serverless v2 capacity setting. A large maximum capacity allows the DB instance to scale up the most when it's running an intensive workload. A low value avoids the possibility of unexpected charges. Depending on how you use that cluster and the other settings that you configure, the most effective value might be higher or lower than you originally thought. Consider the following factors when choosing the maximum capacity setting:

- The maximum capacity must be at least as high as the minimum capacity. You can set the minimum and maximum capacity to be identical. However, in that case the capacity never scales up or down. Thus, using identical values for minimum and maximum capacity isn't appropriate outside of testing situations.
- The maximum capacity must be higher than 0.5 ACUs. You can set the minimum and maximum capacity to be the same in most cases. However, you can't specify 0.5 for both the minimum and maximum. Use a value of 1 or higher for the maximum capacity.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to estimate the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of high traffic, consult Hardware specifications for DB instance classes for Aurora.

  For example, suppose that you use the db.r6g.4xlarge DB instance class when your cluster has a high workload. That DB instance class has 128 GiB of memory. Thus, you can specify a maximum ACU setting of 64 to set up an Aurora Serverless v2 DB instance that can scale up to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat higher value to let the DB instance scale up farther in case your db.r6g.4xlarge DB instance sometimes doesn't have enough capacity to handle the workload effectively.
- If you have a budgetary cap on your database usage, choose a value that stays within that cap even if all your Aurora Serverless v2 DB instances run at maximum capacity all the time. Remember that when you have *n* Aurora Serverless v2 DB instances in your cluster, the theoretical maximum Aurora Serverless v2 capacity that the cluster can consume at any moment is *n* times the maximum ACU setting for the cluster. (The actual amount consumed might be less, for example if some readers scale independently from the writer.)
- If you make use of Aurora Serverless v2 reader DB instances to offload some of the read-only workload from the writer DB instance, you might be able to choose a lower maximum capacity

setting. You do this to reflect that each reader DB instance doesn't need to scale as high as if the cluster contains only a single DB instance.

- Suppose that you want to protect against excessive usage due to misconfigured database parameters or inefficient queries in your application. In that case, you might avoid accidental overuse by choosing a maximum capacity setting that's lower than the absolute highest that you could set.
- If spikes due to real user activity are rare but do happen, you can take those occasions into account when choosing the maximum capacity setting. If the priority is for the application to keep running with full performance and scalability, you can specify a maximum capacity setting that's higher than you observe in normal usage. If it's OK for the application to run with reduced throughput during very extreme spikes in activity, you can choose a slightly lower maximum capacity setting. Make sure that you choose a setting that still has enough memory and CPU resources to keep the application running.
- If you turn on settings in your cluster that increase the memory usage for each DB instance, take that memory into account when deciding on the maximum ACU value. Such settings include those for Performance Insights, Aurora MySQL parallel queries, Aurora MySQL performance schema, and Aurora MySQL binary log replication. Make sure that the maximum ACU value allows the Aurora Serverless v2 DB instances to scale up enough to handle the workload when those feature are being used. For information about troubleshooting problems caused by the combination of a low maximum ACU setting and Aurora features that impose memory overhead, see Avoiding out-of-memory errors.

Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster

The following AWS CLI example shows how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora MySQL cluster. Initially, the capacity range for the cluster is 8–32 ACUs.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
}
```

The DB instance is idle and scaled down to 8 ACUs. The following capacity-related settings apply to the DB instance at this point. To represent the size of the buffer pool in easily readable units, we divide it by 2 to the power of 30, yielding a measurement in gibibytes (GiB). That's because memory-related measurements for Aurora use units based on powers of 2, not powers of 10.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                9294577664 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|   8.65625 |
+-----------+
1 row in set (0.00 sec)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
}
```

Changing the capacity range caused changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that a reboot is needed to apply some parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `innodb_buffer_pool_size` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

Note

If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|              15572402176 |
+--------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+---------------+
| gibibytes     |
+---------------+
| 14.5029296875 |
+---------------+
1 row in set (0.00 sec)
```

Now we reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

The `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "in-sync"
        }
    ]
}
```

The `innodb_buffer_pool_size` parameter has increased to its final size for an idle DB instance. The `max_connections` parameter has increased to reflect a value derived from the maximum ACU value. The formula that Aurora uses for `max_connections` causes an increase of 1,000 when the memory size doubles.

```
mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|               16139681792 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|  15.03125 |
+-----------+
1 row in set (0.00 sec)

mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              4000 |
+-------------------+
1 row in set (0.00 sec)
```

We set the capacity range to 0.5–128 ACUs, and reboot the DB instance. Now the idle DB instance has a buffer cache size that's less than 1 GiB, so we measure it in mebibytes (MiB). The `max_connections` value of 5000 is derived from the memory size of the maximum capacity setting.

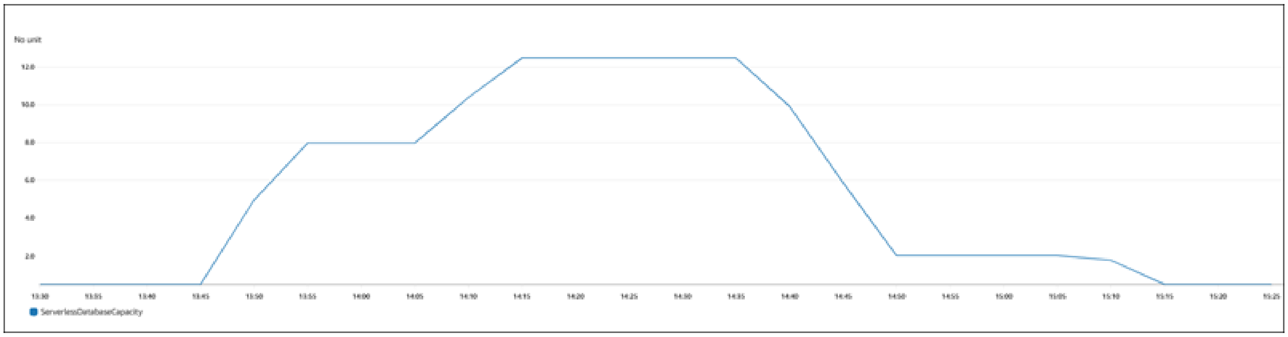
```
mysql> select @@innodb_buffer_pool_size / pow(2,20) as mebibytes, @@max_connections;
+-----------+-------------------+
| mebibytes | @@max_connections |
+-----------+-------------------+
|       672 |              5000 |
+-----------+-------------------+
1 row in set (0.00 sec)
```

Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster

The following CLI examples show how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora PostgreSQL cluster.

1. The capacity range for the cluster starts at 0.5–1 ACU.
2. Change the capacity range to 8–32 ACUs.
3. Change the capacity range to 12.5–80 ACUs.
4. Change the capacity range to 0.5–128 ACUs.
5. Return the capacity to its initial range of 0.5–1 ACU.

The following figure shows the capacity changes in Amazon CloudWatch.



The DB instance is idle and scaled down to 0.5 ACUs. The following capacity-related settings apply to the DB instance at this point.

```
postgres=> show max_connections;
 max_connections
-----------------
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
(1 row)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 8.0–32.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
}
```

Changing the capacity range causes changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that you need a reboot to apply some parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 8.0 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

Note

If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```
postgres=> show max_connections;
 max_connections
-----------------
```

```
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 1425408
(1 row)
```

We reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "in-sync"
        }
    ]
}
```

After rebooting, `max_connections` shows the value from the new maximum capacity.

```
postgres=> show max_connections;
 max_connections
-----------------
 5000
(1 row)
```

```

postgres=> show shared_buffers;
 shared_buffers
----------------
 1425408
(1 row)
```

Next, we change the capacity range for the cluster to 12.5–80 ACUs.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` value is still 5000.

```
postgres=> show max_connections;
 max_connections
-----------------
 5000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 2211840
(1 row)
```

We reboot again, but the parameter values stay the same. This is because `max_connections` has a maximum value of 5000 for an Aurora Serverless v2 DB cluster running Aurora PostgreSQL.

```
postgres=> show max_connections;
 max_connections
-----------------
```

```
 5000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 2211840
(1 row)
```

Now we set the capacity range from 0.5 to 128 ACUs. The DB cluster scales down to 10 ACUs, then to 2. We reboot the DB instance.

```
postgres=> show max_connections;
 max_connections
-----------------
 2000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
(1 row)
```

The `max_connections` value for Aurora Serverless v2 DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

Now we return the capacity to its initial range of 0.5–1 ACU and reboot the DB instance. The `max_connections` parameter has returned to its original value.

```
postgres=> show max_connections;
 max_connections
-----------------
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
```

```
(1 row)
```

Working with parameter groups for Aurora Serverless v2

When you create your Aurora Serverless v2 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. If you aren't familiar with how Aurora uses parameter groups to apply configuration settings consistently across clusters, see Working with parameter groups. All of those procedures for creating, modifying, applying, and other actions for parameter groups apply to Aurora Serverless v2.

The parameter group feature works generally the same between provisioned clusters and clusters containing Aurora Serverless v2 DB instances:

- The default parameter values for all DB instances in the cluster are defined by the cluster parameter group.
- You can override some parameters for specific DB instances by specifying a custom DB parameter group for those DB instances. You might do so during debugging or performance tuning for specific DB instances. For example, suppose that you have a cluster containing some Aurora Serverless v2 DB instances and some provisioned DB instances. In this case, you might specify some different parameters for the provisioned DB instances by using a custom DB parameter group.
- For Aurora Serverless v2, you can use all the parameters that have the value `provisioned` in the `SupportedEngineModes` attribute in the parameter group. In Aurora Serverless v1, you can only use the subset of parameters that have `serverless` in the `SupportedEngineModes` attribute.

Topics

Default parameter values

The crucial difference between provisioned DB instances and Aurora Serverless v2 DB instances is that Aurora overrides any custom parameter values for certain parameters that are related to

DB instance capacity. The custom parameter values still apply to any provisioned DB instances in your cluster. For more details about how Aurora Serverless v2 DB instances interpret the parameters from Aurora parameter groups, see Configuration parameters for Aurora clusters. For the specific parameters that Aurora Serverless v2 overrides, see Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down and Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the describe-db-cluster-parameters CLI command and querying the AWS Region. The following are values that you can use for the `--db-parameter-group-family` and `-db-parameter-group-name` options for engine versions that are compatible with Aurora Serverless v2.

Database engine and version	Parameter group family	Default parameter group name
Aurora MySQL version 3	`aurora-mysql8.0`	`default.aurora-mysql8.0`
Aurora PostgreSQL version 13.x	`aurora-postgresql13`	`default.aurora-postgresql13`
Aurora PostgreSQL version 14.x	`aurora-postgresql14`	`default.aurora-postgresql14`
Aurora PostgreSQL version 15.x	`aurora-postgresql15`	`default.aurora-postgresql15`
Aurora PostgreSQL version 16.x	`aurora-postgresql16`	`default.aurora-postgresql16`

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 3 and Aurora PostgreSQL 13. Those are the Aurora MySQL and Aurora PostgreSQL versions that you use with Aurora Serverless v2.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name default.aurora-mysql8.0 \
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \
  --output text

aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name default.aurora-postgresql13 \
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \
  --output text
```

For Windows:

```
aws rds describe-db-cluster-parameters ^
  --db-cluster-parameter-group-name default.aurora-mysql8.0 ^
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^
  --output text

aws rds describe-db-cluster-parameters ^
  --db-cluster-parameter-group-name default.aurora-postgresql13 ^
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^
  --output text
```

Maximum connections for Aurora Serverless v2

For both Aurora MySQL and Aurora PostgreSQL, Aurora Serverless v2 DB instances hold the `max_connections` parameter constant so that connections aren't dropped when the DB instance scales down. The default value for this parameter is derived from a formula based on the memory size of the DB instance. For details about the formula and the default values for provisioned DB instance classes, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

When Aurora Serverless v2 evaluates the formula, it uses the memory size based on the maximum Aurora capacity units (ACUs) for the DB instance, not the current ACU value. If you change the default value, we recommend using a variation of the formula instead of specifying a constant value. That way, Aurora Serverless v2 can use an appropriate setting based on the maximum capacity.

When you change the maximum capacity of an Aurora Serverless v2 DB cluster, you have to reboot the Aurora Serverless v2 DB instances to update the `max_connections` value. This is because `max_connections` is a static parameter for Aurora Serverless v2.

The following table shows the default values for `max_connections` for Aurora Serverless v2 based on the maximum ACU value.

Maximum ACUs	Default maximum connections on Aurora MySQL	Default maximum connections on Aurora PostgreSQL
1	90	189
4	135	823
8	1,000	1,669
16	2,000	3,360
32	3,000	5,000
64	4,000	5,000
128	5,000	5,000

Note

The `max_connections` value for Aurora Serverless v2DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

For specific examples showing how `max_connections` changes with the maximum ACU value, see Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster and Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster.

Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down

During autoscaling, Aurora Serverless v2 needs to be able to change parameters for each DB instance to work best for the increased or decreased capacity. Thus, you can't override some parameters related to capacity. For some parameters that you can override, avoid hardcoding fixed values. The following considerations apply to these settings that are related to capacity.

For Aurora MySQL, Aurora Serverless v2 resizes some parameters dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `innodb_buffer_pool_size`
- `innodb_purge_threads`
- `table_definition_cache`
- `table_open_cache`

For Aurora PostgreSQL, Aurora Serverless v2 resizes the following parameter dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `shared_buffers`

For all parameters other than those listed here, Aurora Serverless v2 DB instances work the same as provisioned DB instances. The default parameter value is inherited from the cluster parameter group. You can modify the default for the whole cluster by using a custom cluster parameter group. Or you can modify the default for certain DB instances by using a custom DB parameter group. Dynamic parameters are updated immediately. Changes to static parameters only take effect after you reboot the DB instance.

Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity

For the following parameters, Aurora PostgreSQL uses default values that are derived from the memory size based on the maximum ACU setting, the same as with `max_connections`:

- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_limit`

- `autovacuum_work_mem`
- `effective_cache_size`
- `maintenance_work_mem`

Avoiding out-of-memory errors

If one of your Aurora Serverless v2 DB instances consistently reaches the limit of its maximum capacity, Aurora indicates this condition by setting the DB instance to a status of `incompatible-parameters`. While the DB instance has the `incompatible-parameters` status, some operations are blocked. For example, you can't upgrade the engine version.

Typically, your DB instance goes into this status when it restarts frequently due to out-of-memory errors. Aurora records an event when this type of restart happens. You can view the event by following the procedure in Viewing Amazon RDS events. Unusually high memory usage can happen because of overhead from turning on settings such as Performance Insights and IAM authentication. It can also come from a heavy workload on your DB instance or from managing the metadata associated with a large number of schema objects.

If the memory pressure becomes lower so that the DB instance doesn't reach its maximum capacity very often, Aurora automatically changes the DB instance status back to `available`.

To recover from this condition, you can take some or all of the following actions:

- Increase the lower limit on capacity for Aurora Serverless v2 DB instances by changing the minimum Aurora capacity unit (ACU) value for the cluster. Doing so avoids issues where an idle database scales down to a capacity with less memory than is needed for the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Increase the upper limit on capacity for Aurora Serverless v2 DB instances by changing the maximum ACU value for the cluster. Doing so avoids issues where a busy database can't scale up to a capacity with enough memory for the features that are turned on in your cluster and the database workload. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Turn off configuration settings that require memory overhead. For example, suppose that you have features such as AWS Identity and Access Management (IAM), Performance Insights, or Aurora MySQL binary log replication turned on but don't use them. If so, you can turn them off.

Or you can adjust the minimum and maximum capacity values for the cluster higher to account for the memory used by those features. For guidelines about choosing minimum and maximum capacity settings, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster.

- Reduce the workload on the DB instance. For example, you can add reader DB instances to the cluster to spread the load from read-only queries across more DB instances.
- Tune the SQL code used by your application to use fewer resources. For example, you can examine your query plans, check the slow query log, or adjust the indexes on your tables. You can also perform other traditional kinds of SQL tuning.

Important Amazon CloudWatch metrics for Aurora Serverless v2

To get started with Amazon CloudWatch for your Aurora Serverless v2 DB instance, see Viewing Aurora Serverless v2 logs in Amazon CloudWatch. To learn more about how to monitor Aurora DB clusters through CloudWatch, see Monitoring log events in Amazon CloudWatch.

You can view your Aurora Serverless v2 DB instances in CloudWatch to monitor the capacity consumed by each DB instance with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `DatabaseConnections` and `Queries`. For the full list of CloudWatch metrics that you can monitor for Aurora, see Amazon CloudWatch metrics for Amazon Aurora. The metrics are divided into cluster-level and instance-level metrics, in Cluster-level metrics for Amazon Aurora and Instance-level metrics for Amazon Aurora.

The following CloudWatch instance-level metrics are important to monitor for you to understand how your Aurora Serverless v2 DB instances are scaling up and down. All of these metrics are calculated every second. That way, you can monitor the current status of your Aurora Serverless v2 DB instances. You can set alarms to notify you if any Aurora Serverless v2 DB instance approaches a threshold for metrics related to capacity. You can determine if the minimum and maximum capacity settings are appropriate, or if you need to adjust them. You can determine where to focus your efforts for optimizing the efficiency of your database.

- `ServerlessDatabaseCapacity`. As an instance-level metric, it reports the number of ACUs represented by the current DB instance capacity. As a cluster-level metric, it represents the average of the `ServerlessDatabaseCapacity` values of all the Aurora Serverless v2 DB instances in the cluster. This metric is only a cluster-level metric in Aurora Serverless v1. In Aurora Serverless v2, it's available at the DB instance level and at the cluster level.

- `ACUUtilization`. This metric is new in Aurora Serverless v2. This value is represented as a percentage. It's calculated as the value of the `ServerlessDatabaseCapacity` metric divided by the maximum ACU value of the DB cluster. Consider the following guidelines to interpret this metric and take action:
  - If this metric approaches a value of `100.0`, the DB instance has scaled up as high as it can. Consider increasing the maximum ACU setting for the cluster. That way, both writer and reader DB instances can scale to a higher capacity.
  - Suppose that a read-only workload causes a reader DB instance to approach an `ACUUtilization` of `100.0`, while the writer DB instance isn't close to its maximum capacity. In that case, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
  - Suppose that you are running a production application, where performance and scalability are the primary considerations. In that case, you can set the maximum ACU value for the cluster to a high number. Your goal is for the `ACUUtilization` metric to always be below `100.0`. With a high maximum ACU value, you can be confident that there's enough room in case there are unexpected spikes in database activity. You are only charged for the database capacity that's actually consumed.
- `CPUUtilization`. This metric is interpreted differently in Aurora Serverless v2 than in provisioned DB instances. For Aurora Serverless v2, this value is a percentage that's calculated as the amount of CPU currently being used divided by the CPU capacity that's available under the maximum ACU value of the DB cluster. Aurora monitors this value automatically and scales up your Aurora Serverless v2 DB instance when the DB instance consistently uses a high proportion of its CPU capacity.

  If this metric approaches a value of `100.0`, the DB instance has reached its maximum CPU capacity. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `100.0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
- `FreeableMemory`. This value represents the amount of unused memory that is available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. For every ACU that the current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of `0`, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance.

- `TempStorageIops`. The number of IOPS done on local storage attached to the DB instance. It includes the IOPS for both reads and writes. This metric represents a count and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see Instance-level metrics for Amazon Aurora.
- `TempStorageThroughput`. The amount of data transferred to and from local storage associated with the DB instance. This metric represents bytes and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see Instance-level metrics for Amazon Aurora.

Typically, most scaling up for Aurora Serverless v2 DB instances is caused by memory usage and CPU activity. The `TempStorageIops` and `TempStorageThroughput` metrics can help you to diagnose the rare cases where network activity for transfers between your DB instance and local storage devices is responsible for unexpected capacity increases. To monitor other network activity, you can use these existing metrics:

- `NetworkReceiveThroughput`
- `NetworkThroughput`
- `NetworkTransmitThroughput`
- `StorageNetworkReceiveThroughput`
- `StorageNetworkThroughput`
- `StorageNetworkTransmitThroughput`

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by turning on the configuration parameters such as `general_log` and `slow_query_log` in the DB cluster parameter group associated with the cluster that contains your Aurora Serverless v2 DB instances. When you turn off a log configuration parameter, publishing that log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

How Aurora Serverless v2 metrics apply to your AWS bill

The Aurora Serverless v2 charges on your AWS bill are calculated based on the same `ServerlessDatabaseCapacity` metric that you can monitor. The billing mechanism can differ from the computed CloudWatch average for this metric in cases where you use Aurora Serverless v2 capacity for only part of an hour. It can also differ if system issues make the CloudWatch metric unavailable for brief periods. Thus, you might see a slightly different value of ACU-hours on your bill than if you compute the number yourself from the `ServerlessDatabaseCapacity` average value.

Examples of CloudWatch commands for Aurora Serverless v2 metrics

The following AWS CLI examples demonstrate how you can monitor the most important CloudWatch metrics related to Aurora Serverless v2. In each case, replace the `Value=` string for the `--dimensions` parameter with the identifier of your own Aurora Serverless v2 DB instance.

The following Linux example displays the minimum, maximum, and average capacity values for a DB instance, measured every 10 minutes over one hour. The Linux `date` command specifies the start and end times relative to the current date and time. The `sort_by` function in the `--query` parameter sorts the results chronologically based on the `Timestamp` field.

```
aws cloudwatch get-metric-statistics --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux examples demonstrate monitoring the capacity of each DB instance in a cluster. They measure the minimum, maximum, and average capacity utilization of each DB instance. The measurements are taken once each hour over a three-hour period. These examples use the `ACUUtilization` metric representing a percentage of the upper limit on ACUs, instead of `ServerlessDatabaseCapacity` representing a fixed number of ACUs. That way, you don't need to know the actual numbers for the minimum and maximum ACU values in the capacity range. You can see percentages ranging from 0 to 100.

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_writer_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table

aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_reader_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `CPUUtilization` metric. The measurements are taken every 10 minutes over a 1-hour period. The numbers represent the percentage of available CPU used, based on the CPU resources available to the maximum capacity setting for the DB instance.

```
aws cloudwatch get-metric-statistics --metric-name "CPUUtilization" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `FreeableMemory` metric. The measurements are taken every 10 minutes over a 1-hour period.

```
aws cloudwatch get-metric-statistics --metric-name "FreeableMemory" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

Monitoring Aurora Serverless v2 performance with Performance Insights

You can use Performance Insights to monitor the performance of Aurora Serverless v2 DB instances. For Performance Insights procedures, see Monitoring DB load with Performance Insights on Amazon Aurora.

The following new Performance Insights counters apply to Aurora Serverless v2 DB instances:

- `os.general.serverlessDatabaseCapacity` – The current capacity of the DB instance in ACUs. The value corresponds to the `ServerlessDatabaseCapacity` CloudWatch metric for the DB instance.
- `os.general.acuUtilization` – The percentage of current capacity out of the maximum configured capacity. The value corresponds to the `ACUUtilization` CloudWatch metric for the DB instance.
- `os.general.maxConfiguredAcu` – The maximum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs.
- `os.general.minConfiguredAcu` – The minimum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs

For the full list of Performance Insights counters, see Performance Insights counter metrics.

When vCPU values are shown for an Aurora Serverless v2 DB instance in Performance Insights, those values represent estimates based on the ACU value for the DB instance. At the default interval of one minute, any fractional vCPU values are rounded up to the nearest whole number. For longer intervals, the vCPU value shown is the average of the integer vCPU values for each minute.

Troubleshooting Aurora Serverless v2 capacity issues

In some cases, Aurora Serverless v2 doesn't scale down to the minimum capacity, even with no load on the database. This can happen for the following reasons:

- Certain features can increase resource usage and prevent the database from scaling down to minimum capacity. These features include the following:
  - Aurora global databases
  - Exporting CloudWatch Logs
  - Enabling `pg_audit` on Aurora PostgreSQL–compatible DB clusters
  - Enhanced Monitoring
  - Performance Insights

  For more information, see Choosing the minimum Aurora Serverless v2 capacity setting for a cluster.

- If a reader instance isn't scaling down to the minimum and stays at the same or higher capacity than the writer instance, then check the priority tier of the reader instance. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. Change the priority tier of the reader to 2 or higher so that it scales up and down independently of the writer. For more information, see Choosing the promotion tier for an Aurora Serverless v2 reader.
- Set any database parameters that impact the size of shared memory to their default values. Setting a value higher than the default increases the shared memory requirement and prevents the database from scaling down to the minimum capacity. Examples are `max_connections` and `max_locks_per_transaction`.

  Note

  Updating shared memory parameters requires a database restart for the changes to take effect.
- Heavy database workloads can increase resource usage.
- Large database volumes can increase resource usage.

  Amazon Aurora uses memory and CPU resources for DB cluster management. Aurora requires more CPU and memory to manage DB clusters with larger database volumes. If your cluster’s minimum capacity is less than the minimum required for cluster management, your cluster won't scale down to the minimum capacity.
- Background processes, such as purge, can also increase resource usage.

If the database still doesn't scale down to the minimum capacity configured, then stop and restart the database to reclaim any memory fragments that might have built up over time. Stopping and starting a database results in downtime, so we recommend doing this sparingly.

Migrating to Aurora Serverless v2

To convert an existing DB cluster to use Aurora Serverless v2, you can do the following:

- Upgrade from a provisioned Aurora DB cluster.
- Upgrade from an Aurora Serverless v1 cluster.
- Migrate from an on-premises database to an Aurora Serverless v2 cluster.

When your upgraded cluster is running the appropriate engine version as listed in Requirements and limitations for Aurora Serverless v2, you can begin adding Aurora Serverless v2 DB instances to it. The first DB instance that you add to the upgraded cluster must be a provisioned DB instance. Then you can switch over the processing for the write workload, the read workload, or both to the Aurora Serverless v2 DB instances.

Contents

Note

These topics describe how to convert an existing DB cluster. For information on creating a new Aurora Serverless v2 DB cluster, see Creating a DB cluster that uses Aurora Serverless v2.

Upgrading or switching existing clusters to use Aurora Serverless v2

If your provisioned cluster has an engine version that supports Aurora Serverless v2, switching to Aurora Serverless v2 doesn't require an upgrade. In that case, you can add Aurora Serverless v2 DB instances to your original cluster. You can switch the cluster to use all Aurora Serverless v2 DB instances. You can also use a combination of Aurora Serverless v2 and provisioned DB instances in the same DB cluster. For the Aurora engine versions that support Aurora Serverless v2, see Supported Regions and Aurora DB engines for Aurora Serverless v2.

If you're running a lower engine version that doesn't support Aurora Serverless v2, you take these general steps:

1. Upgrade the cluster.
2. Create a provisioned writer DB instance for the upgraded cluster.
3. Modify the cluster to use Aurora Serverless v2 DB instances.

> ⚠ **Important**
>
> When you perform a major version upgrade to an Aurora Serverless v2-compatible version by using snapshot restore or cloning, the first DB instance that you add to the new cluster must be a provisioned DB instance. This addition starts the final stage of the upgrade process.
> Until that final stage happens, the cluster doesn't have the infrastructure that's required for Aurora Serverless v2 support. Thus, these upgraded clusters always start with a provisioned writer DB instance. Then you can convert or fail over the provisioned DB instance to an Aurora Serverless v2 one.

Upgrading from Aurora Serverless v1 to Aurora Serverless v2 involves creating a provisioned cluster as an intermediate step. Then you perform the same upgrade steps as when you start with a provisioned cluster.

Upgrade paths for MySQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora MySQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora MySQL version 3, compatible with MySQL 8.0	This is the final stage for all conversions from existing Aurora MySQL clusters. If necessary, perform a minor version upgrade to version 3.02.0 or higher. Use a provisioned

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
	DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that the writer DB instance. (Optional) Convert other provisioned DB instances in the cluster to Aurora Serverles s v2. Or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances. For the full procedure and examples, see Switching from a provisioned cluster to Aurora Serverless v2.
Provisioned cluster running Aurora MySQL version 2, compatible with MySQL 5.7	Perform a major version upgrade to Aurora MySQL version 3.02.0 or higher. Then follow the procedure for Aurora MySQL version 3 to switch the cluster to use Aurora Serverless v2 DB instances.
Aurora Serverless v1 cluster running Aurora MySQL version 2, compatible with MySQL 5.7	To help plan your conversion from Aurora Serverless v1, consult Comparison of Aurora Serverless v2 and Aurora Serverless v1 first. Then follow the procedure in Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2.

Upgrade paths for PostgreSQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora PostgreSQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora PostgreSQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora PostgreSQL version 13	This is the final stage for all conversions from existing Aurora PostgreSQL clusters. If necessary, perform a minor version upgrade to version 13.6 or higher. Add one provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that Aurora Serverless v2 instance the writer DB instance. (Optional) Convert other provisioned DB instances in the cluster to Aurora Serverless v2. Or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances. For the full procedure and examples, see Switching from a provisioned cluster to Aurora Serverless v2.
Provisioned cluster running Aurora PostgreSQL version 11 or 12	Perform a major version upgrade to Aurora PostgreSQL version 13.6 or higher. Then follow the procedure for Aurora PostgreSQL version 13 to switch the cluster to use Aurora Serverless v2 DB instances.
Aurora Serverless v1 cluster running Aurora PostgreSQL version 11 or 13	To help plan your conversion from Aurora Serverless v1, consult Comparison of Aurora Serverless v2 and Aurora Serverless v1 first. Then follow the procedure in Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2.

Switching from a provisioned cluster to Aurora Serverless v2

To switch a provisioned cluster to use Aurora Serverless v2, follow these steps:

1. Check if the provisioned cluster needs to be upgraded to be used with Aurora Serverless v2 DB instances. For the Aurora versions that are compatible with Aurora Serverless v2, see Requirements and limitations for Aurora Serverless v2.

   If the provisioned cluster is running an engine version that isn't available for Aurora Serverless v2, upgrade the engine version of the cluster:

   - If you have a MySQL 5.7–compatible provisioned cluster, follow the upgrade instructions for Aurora MySQL version 3. Use the procedures in How to perform an in-place upgrade.
   - If you have a PostgreSQL-compatible provisioned cluster running PostgreSQL version 11 or 12, follow the upgrade instructions for Aurora PostgreSQL version 13. Use the procedures in How to perform a major version upgrade.
2. Configure any other cluster properties to match the Aurora Serverless v2 requirements from Requirements and limitations for Aurora Serverless v2.
3. Configure the scaling configuration for the cluster. Follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster.
4. Add one or more Aurora Serverless v2 DB instances to the cluster. Follow the general procedure in Adding Aurora Replicas to a DB cluster. For each new DB instance, specify the special DB instance class name **Serverless** in the AWS Management Console, or `db.serverless` in the AWS CLI or Amazon RDS API.

   In some cases, you might already have one or more provisioned reader DB instances in the cluster. If so, you can convert one of the readers to an Aurora Serverless v2 DB instance instead of creating a new DB instance. To do so, follow the procedure in Converting a provisioned writer or reader to Aurora Serverless v2.
5. Perform a failover operation to make one of the Aurora Serverless v2 DB instances the writer DB instance for the cluster.
6. (Optional) Convert any provisioned DB instances to Aurora Serverless v2, or remove them from the cluster. Follow the general procedure in Converting a provisioned writer or reader to Aurora Serverless v2 or Deleting a DB instance from an Aurora DB cluster.

Tip

Removing the provisioned DB instances isn't mandatory. You can set up a cluster containing both Aurora Serverless v2 and provisioned DB instances. However, until you are familiar with the performance and scaling characteristics of Aurora Serverless v2 DB instances, we recommend that you configure your clusters with DB instances all of the same type.

The following AWS CLI example shows the switchover process using a provisioned cluster that's running Aurora MySQL version 3.02.0. The cluster is named `mysql-80`. The cluster starts with two provisioned DB instances named `provisioned-instance-1` and `provisioned-instance-2`, a writer and a reader. They both use the `db.r6g.large` DB instance class.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
  --query '*[].[DBClusterIdentifier,DBClusterMembers[*].
[DBInstanceIdentifier,IsClusterWriter]]' --output text
mysql-80
provisioned-instance-2     False
provisioned-instance-1     True

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-1 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-1     db.r6g.large

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-2 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-2     db.r6g.large
```

We create a table with some data. That way, we can confirm that the data and operation of the cluster are the same before and after the switchover.

```
mysql> create database serverless_v2_demo;
mysql> create table serverless_v2_demo.demo (s varchar(128));
mysql> insert into serverless_v2_demo.demo values ('This cluster started with a
 provisioned writer.');
Query OK, 1 row affected (0.02 sec)
```

First, we add a capacity range to the cluster. Otherwise, we get an error when adding any Aurora Serverless v2 DB instances to the cluster. If we use the AWS Management Console for this procedure, that step is automatic when we add the first Aurora Serverless v2 DB instance.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 \
  --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-
mysql

An error occurred (InvalidDBClusterStateFault) when calling the CreateDBInstance
 operation:
Set the Serverless v2 scaling configuration on the parent DB cluster before creating a
 Serverless v2 DB instance.

$ # The blank ServerlessV2ScalingConfiguration attribute confirms that the cluster
 doesn't have a capacity range set yet.
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 --query
 'DBClusters[*].ServerlessV2ScalingConfiguration'
[]

$ aws rds modify-db-cluster --db-cluster-identifier mysql-80 \
  --serverless-v2-scaling-configuration MinCapacity=0.5,MaxCapacity=16
{
  "DBClusterIdentifier": "mysql-80",
  "ServerlessV2ScalingConfiguration": {
    "MinCapacity": 0.5,
    "MaxCapacity": 16
  }
}
```

We create two Aurora Serverless v2 readers to take the place of the original DB instances. We do so by specifying the `db.serverless` DB instance class for the new DB instances.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 --db-
cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceStatus": "creating"
}

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-2 \
  --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-
mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-2",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceStatus": "creating"
}

$ # Wait for both DB instances to finish being created before proceeding.
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
 && \
  aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-2
```

We perform a failover to make one of the Aurora Serverless v2 DB instances the new writer for the cluster.

```
$ aws rds failover-db-cluster --db-cluster-identifier mysql-80 \
  --target-db-instance-identifier serverless-v2-instance-1
{
  "DBClusterIdentifier": "mysql-80",
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "serverless-v2-instance-2",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "provisioned-instance-2",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "provisioned-instance-1",
      "IsClusterWriter": true,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    }
  ],
  "Status": "available"
}
```

It takes a few seconds for that change to take effect. At that point, we have an Aurora Serverless v2 writer and an Aurora Serverless v2 reader. Thus, we don't need either of the original provisioned DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
  --query '*[].[DBClusterIdentifier,DBClusterMembers[*].
[DBInstanceIdentifier,IsClusterWriter]]' \
  --output text
mysql-80
serverless-v2-instance-1        True
serverless-v2-instance-2        False
provisioned-instance-2          False
provisioned-instance-1          False
```

The last step in the switchover procedure is to delete both of the provisioned DB instances.

```
$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-2 --skip-
final-snapshot
{
  "DBInstanceIdentifier": "provisioned-instance-2",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceClass": "db.r6g.large"
}

$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-1 --skip-
final-snapshot
{
  "DBInstanceIdentifier": "provisioned-instance-1",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceClass": "db.r6g.large"
}
```

As a final check, we confirm that the original table is accessible and writeable from the Aurora Serverless v2 writer DB instance.

```
mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
| This cluster started with a provisioned writer.  |
+---------------------------------------------------+
1 row in set (0.00 sec)

mysql> insert into serverless_v2_demo.demo values ('And it finished with a Serverless
 v2 writer.');
Query OK, 1 row affected (0.01 sec)

mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
| This cluster started with a provisioned writer.  |
| And it finished with a Serverless v2 writer.      |
+---------------------------------------------------+
2 rows in set (0.01 sec)
```

We also connect to the Aurora Serverless v2 reader DB instance and confirm that the newly written data is available there too.

```
mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
| This cluster started with a provisioned writer.  |
| And it finished with a Serverless v2 writer.      |
+---------------------------------------------------+
2 rows in set (0.01 sec)
```

Comparison of Aurora Serverless v2 and Aurora Serverless v1

If you are already using Aurora Serverless v1, you can learn the major differences between Aurora Serverless v1 and Aurora Serverless v2. The architectural differences, such as support for reader DB instances, open up new types of use cases.

You can use the following tables to help understand the most important differences between Aurora Serverless v2 and Aurora Serverless v1.

Topics

Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements

The following table summarizes the different requirements to run your database using Aurora Serverless v2 or Aurora Serverless v1. Aurora Serverless v2 offers higher versions of the Aurora MySQL and Aurora PostgreSQL DB engines than Aurora Serverless v1 does.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
DB engines	Aurora MySQL, Aurora PostgreSQL	Aurora MySQL, Aurora PostgreSQL
Supported Aurora MySQL versions	See Aurora Serverless v2 with Aurora MySQL.	See Aurora Serverless v1 with Aurora MySQL.
Supported Aurora PostgreSQL versions	See Aurora Serverless v2 with Aurora PostgreSQL.	See Aurora Serverless v1 with Aurora PostgreSQL.
Upgrading a DB cluster	Similarly to provisioned DB clusters, you can perform upgrades manually without waiting for Aurora to upgrade the DB cluster for you. For more information, see Modifying an Amazon Aurora DB cluster.	Minor version upgrades are applied automatically as they become available. For more information, see Aurora Serverless v1 and Aurora database engine versions. You can perform major version upgrades manually. For more information,

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
	Note To perform a major version upgrade from 13.x to 14.x or 15.x for an Aurora PostgreSQL–compatible DB cluster, the maximum capacity of your cluster must be at least 2 ACUs.	see Modifying an Aurora Serverless v1 DB cluster.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
Converting from provisioned DB cluster	You can use the following methods: • Add one or more Aurora Serverless v2 reader DB instances to an existing provisioned cluster. To use Aurora Serverless v2 for the writer, perform a failover to one of the Aurora Serverles s v2 DB instances. For the entire cluster to use Aurora Serverless v2 DB instances , remove any provisioned writer DB instances after promoting the Aurora Serverless v2 DB instance to the writer. • Create a new cluster with the appropriate DB engine and engine version. Use any of the standard methods. For example, restore a cluster snapshot or create a clone of an existing cluster. Choose Aurora Serverless v2 for some or all of the DB instances in the new cluster. If you create the new cluster through cloning, you can't upgrade the engine version at the same time. Make sure that the	Restore snapshot of provision ed cluster to create new Aurora Serverless v1 cluster.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
	original cluster is already running an engine version that's compatible with Aurora Serverless v2.	
Converting from Aurora Serverless v1 cluster	Follow the procedure in Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2.	Not applicable
Available DB instance classes	The special DB instance class `db.serverless` . In the AWS Management Console, it's labeled as **Serverless**.	Not applicable. Aurora Serverless v1 uses the `serverless` engine mode.
Port	Any port that's compatible with MySQL or PostgreSQL	Default MySQL or PostgreSQL port only
Public IP address allowed?	Yes	No
Virtual private cloud (VPC) required?	Yes	Yes. Each Aurora Serverless v1 cluster consumes 2 interface and Gateway Load Balancer endpoints allocated to your VPC.

Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability

The following table summarizes differences between Aurora Serverless v2 and Aurora Serverless v1 for scalability and availability.

Aurora Serverless v2 scaling is more responsive, more granular, and less disruptive than the scaling in Aurora Serverless v1. Aurora Serverless v2 can scale both by changing the size of the DB instance and by adding more DB instances to the DB cluster. It can also scale by adding clusters in other AWS Regions to an Aurora global database. In contrast, Aurora Serverless v1 only scales by increasing or decreasing the capacity of the writer. All the compute for an Aurora Serverless v1 cluster runs in a single Availability Zone and a single AWS Region.

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Minimum Aurora capacity units (ACUs) (Aurora MySQL)	0.5	1 when the cluster is running, 0 when the cluster is paused.
Minimum ACUs (Aurora PostgreSQL)	0.5	2 when the cluster is running, 0 when the cluster is paused.
Maximum ACUs (Aurora MySQL)	128	256
Maximum ACUs (Aurora PostgreSQL)	128	384
Stopping a cluster	You can manually stop and start the cluster by using the same cluster stop and start feature as provisioned clusters.	The cluster pauses automatically after a timeout. It takes some time to become available when activity resumes.
Scaling for DB instances	Scale up and down with minimum increment of 0.5 ACUs.	Scale up and down by doubling or halving the ACUs.
Number of DB instances	Same as a provisioned cluster: 1 writer DB instance, up to 15 reader DB instances.	1 DB instance handling both reads and writes.
Scaling can happen while SQL statements are running?	Yes. Aurora Serverless v2 doesn't require waiting for a quiet point.	No. For example, scaling waits for completion of long-running transactions, temporary tables, and table locks.

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Reader DB instances scale along with writer	Optional.	Not applicable.
Maximum storage	128 TiB	128 TiB or 64 TiB, depending on database engine and version.
Buffer cache preserved when scaling	Yes. Buffer cache is resized dynamically.	No. Buffer cache is rewarmed after scaling.
Failover	Yes, same as for provisioned clusters.	Best effort only, subject to capacity availability. Slower than in Aurora Serverless v2.
Multi-AZ capability	Yes, same as for provisioned. A Multi-AZ cluster requires a reader DB instance in a second Availability Zone (AZ). For a Multi-AZ cluster, Aurora performs Multi-AZ failover in case of an AZ failure.	Aurora Serverless v1 clusters run all their compute in a single AZ. Recovery in case of AZ failure is best effort only and subject to capacity availability.
Aurora global databases	Yes	No
Scaling based on memory pressure	Yes	No
Scaling based on CPU load	Yes	Yes

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Scaling based on network traffic	Yes, based on memory and CPU overhead of network traffic. The `max_connections` parameter remains constant to avoid dropping connections when scaling down.	Yes, based on number of connections.
Timeout action for scaling events	No	Yes
Adding new DB instances to cluster through AWS Auto Scaling	Not applicable. You can create Aurora Serverless v2 reader DB instances in promotion tiers 2–15 and leave them scaled down to low capacity.	No. Reader DB instances aren't available.

Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support

The following table summarizes these:

- Features that are available in Aurora Serverless v2 but not Aurora Serverless v1
- Features that work differently between Aurora Serverless v1 and Aurora Serverless v2
- Features that aren't currently available in Aurora Serverless v2

Aurora Serverless v2 includes many features from provisioned clusters that aren't available for Aurora Serverless v1.

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
Cluster topology	Aurora Serverless v2 is a property of individual DB instances. A cluster can	Aurora Serverless v1 clusters don't use the notion of DB instances. You can't change

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
	contain multiple Aurora Serverless v2 DB instances, or a combination of Aurora Serverless v2 and provisioned DB instances.	the Aurora Serverless v1 property after you create the cluster.
Configuration parameters	Almost all the same parameters can be modified as in provisioned clusters. For details, see Working with parameter groups for Aurora Serverless v2.	Only a subset of parameters can be modified.
Parameter groups	Cluster parameter group and DB parameter groups. Parameters with `provisioned` value in `SupportedEngineModes` attribute are available. That's many more parameters than in Aurora Serverless v1.	Cluster parameter group only. Parameters with `serverless` value in `SupportedEngineModes` attribute are available.
Encryption for cluster volume	Optional	Required. The limitations in Limitations of Amazon Aurora encrypted DB clusters apply to all Aurora Serverless v1 clusters.
Cross-Region snapshots	Yes	Snapshot must be encrypted with your own AWS Key Management Service (AWS KMS) key.
Automated backups retained after DB cluster deletion	Yes	No

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
TLS/SSL	Yes. The support is the same as for provisioned clusters. For usage information, see Using TLS/SSL with Aurora Serverless v2.	Yes. There are some differenc es from TLS support for provisioned clusters. For usage information, see Using TLS/SSL with Aurora Serverless v1.
Cloning	Only from and to DB engine versions that are compatibl e with Aurora Serverless v2. You can't use cloning to upgrade from Aurora Serverless v1 or from an earlier version of a provision ed cluster.	Only from and to DB engine versions that are compatible with Aurora Serverless v1.
Integration with Amazon S3	Yes	Yes
Integration with AWS Secrets Manager	No	No
Exporting DB cluster snapshots to S3	Yes	No
Associating an IAM role	Yes	No
Uploading logs to Amazon CloudWatch	Optional. You choose which logs to turn on and which logs to upload to CloudWatc h.	All logs that are turned on are uploaded to CloudWatch automatically.
Data API available	Yes	Yes
Query editor available	Yes	Yes
Performance Insights	Yes	No

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
Amazon RDS Proxy available	Yes	No
Babelfish for Aurora PostgreSQL available	Yes. Supported for Aurora PostgreSQL versions that are compatible with both Babelfish and Aurora Serverless v2.	No

Adapting Aurora Serverless v1 use cases to Aurora Serverless v2

Depending on your use case for Aurora Serverless v1, you might adapt that approach to take advantage of Aurora Serverless v2 features as follows.

Suppose that you have an Aurora Serverless v1 cluster that is lightly loaded and your priority is maintaining continuous availability while minimizing costs. With Aurora Serverless v2, you can configure a smaller minimum ACU setting of 0.5, compared with a minimum of 1 ACU for Aurora Serverless v1. You can increase availability by creating a Multi-AZ configuration, with the reader DB instance also having a minimum of 0.5 ACUs.

Suppose that you have an Aurora Serverless v1 cluster that you use in a development and test scenario. In this case, cost is also a high priority but the cluster doesn't need to be available at all times. Currently, Aurora Serverless v2 doesn't automatically pause when the cluster is completely idle. Instead, you can manually stop the cluster when it's not needed, and start it when it's time for the next test or development cycle.

Suppose that you have an Aurora Serverless v1 cluster with a heavy workload. An equivalent cluster using Aurora Serverless v2 can scale with more granularity. For example, Aurora Serverless v1 scales by doubling the capacity, for example from 64 to 128 ACUs. In contrast, your Aurora Serverless v2 DB instance can scale to a value somewhere between those numbers.

Suppose that your workload requires a higher total capacity than is available in Aurora Serverless v1. You can use multiple Aurora Serverless v2 reader DB instances to offload the read-intensive parts of the workload from the writer DB instance. You can also divide the read-intensive workload among multiple reader DB instances.

For a write-intensive workload, you might configure the cluster with a large provisioned DB instance as the writer. You might do so alongside one or more Aurora Serverless v2 reader DB instances.

Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2

The process of upgrading a DB cluster from Aurora Serverless v1 to Aurora Serverless v2 has multiple steps. That's because you can't convert directly from Aurora Serverless v1 to Aurora Serverless v2. There's always an intermediate step that involves converting the Aurora Serverless v1 DB cluster to a provisioned cluster.

Aurora MySQL–compatible DB clusters

You can convert your Aurora Serverless v1 DB cluster to a provisioned DB cluster, then use a blue/green deployment to upgrade it and convert it to an Aurora Serverless v2 DB cluster. We recommend this procedure for production environments. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

To use a blue/green deployment to upgrade an Aurora Serverless v1 cluster running Aurora MySQL version 2 (MySQL 5.7–compatible)

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora MySQL version 2 cluster. Follow the procedure in Converting from Aurora Serverless v1 to provisioned.
2. Create a blue/green deployment. Follow the procedure in Creating a blue/green deployment.
3. Choose an Aurora MySQL version for the green cluster that's compatible with Aurora Serverless v2, for example 3.04.1.

   For compatible versions, see Aurora Serverless v2 with Aurora MySQL.
4. Modify the writer DB instance of the green cluster to use the **Serverless v2** (db.serverless) DB instance class.

   For details, see Converting a provisioned writer or reader to Aurora Serverless v2.
5. When your upgraded Aurora Serverless v2 DB cluster is available, switch over from the blue cluster to the green cluster.

Aurora PostgreSQL–compatible DB clusters

You can convert your Aurora Serverless v1 DB cluster to a provisioned DB cluster, then use a blue/green deployment to upgrade it and convert it to an Aurora Serverless v2 DB cluster. We recommend this procedure for production environments. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

To use a blue/green deployment to upgrade an Aurora Serverless v1 cluster running Aurora PostgreSQL version 11

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora PostgreSQL cluster. Follow the procedure in Converting from Aurora Serverless v1 to provisioned.
2. Create a blue/green deployment. Follow the procedure in Creating a blue/green deployment.
3. Choose an Aurora PostgreSQL version for the green cluster that's compatible with Aurora Serverless v2, for example 15.3.

   For compatible versions, see Aurora Serverless v2 with Aurora PostgreSQL.
4. Modify the writer DB instance of the green cluster to use the **Serverless v2** (db.serverless) DB instance class.

   For details, see Converting a provisioned writer or reader to Aurora Serverless v2.
5. When your upgraded Aurora Serverless v2 DB cluster is available, switch over from the blue cluster to the green cluster.

You can also upgrade your Aurora Serverless v1 DB cluster directly from Aurora PostgreSQL version 11 to version 13, convert it to a provisioned DB cluster, and then convert the provisioned cluster to an Aurora Serverless v2 DB cluster.

To upgrade, then convert an Aurora Serverless v1 cluster running Aurora PostgreSQL version 11

1. Upgrade the Aurora Serverless v1 cluster to an Aurora PostgreSQL version 13 version that's compatible with Aurora Serverless v2, for example, 13.12. Follow the procedure in Upgrading the major version.

   For compatible versions, see Aurora Serverless v2 with Aurora PostgreSQL.
2. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora PostgreSQL cluster. Follow the procedure in Converting from Aurora Serverless v1 to provisioned.

3. Add an Aurora Serverless v2 reader DB instance to the cluster. For more information, see Adding an Aurora Serverless v2 reader.
4. Fail over to the Aurora Serverless v2 DB instance:

   a. Select the writer DB instance of the DB cluster.

   b. For **Actions**, choose **Failover**.

   c. On the confirmation page, choose **Failover**.

For Aurora Serverless v1 DB clusters running Aurora PostgreSQL version 13, you convert the Aurora Serverless v1 cluster to a provisioned DB cluster, and then convert the provisioned cluster to an Aurora Serverless v2 DB cluster.

To upgrade an Aurora Serverless v1 cluster running Aurora PostgreSQL version 13

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora PostgreSQL cluster. Follow the procedure in Converting from Aurora Serverless v1 to provisioned.
2. Add an Aurora Serverless v2 reader DB instance to the cluster. For more information, see Adding an Aurora Serverless v2 reader.
3. Fail over to the Aurora Serverless v2 DB instance:

   a. Select the writer DB instance of the DB cluster.

   b. For **Actions**, choose **Failover**.

   c. On the confirmation page, choose **Failover**.

Migrating from an on-premises database to Aurora Serverless v2

You can migrate your on-premises databases to Aurora Serverless v2, just as with provisioned Aurora MySQL and Aurora PostgreSQL.

- For MySQL databases, you can use the `mysqldump` command. For more information, see Importing data to a MySQL or MariaDB DB instance with reduced downtime.
- For PostgreSQL databases, you can use the `pg_dump` and `pg_restore` commands. For more information, see the blog post Best practices for migrating PostgreSQL databases to Amazon RDS and Amazon Aurora.

Using Amazon Aurora Serverless v1

Amazon Aurora Serverless v1 (Amazon Aurora Serverless version 1) is an on-demand autoscaling configuration for Amazon Aurora. An *Aurora Serverless v1 DB cluster* is a DB cluster that scales compute capacity up and down based on your application's needs. This contrasts with Aurora *provisioned DB clusters*, for which you manually manage capacity. Aurora Serverless v1 provides a relatively simple, cost-effective option for infrequent, intermittent, or unpredictable workloads. It is cost-effective because it automatically starts up, scales compute capacity to match your application's usage, and shuts down when it's not in use.

To learn more about pricing, see Serverless Pricing under **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition** on the Amazon Aurora pricing page.

Aurora Serverless v1 clusters have the same kind of high-capacity, distributed, and highly available storage volume that is used by provisioned DB clusters.

For an Aurora Serverless v2 cluster, you can choose whether to encrypt the cluster volume.

For an Aurora Serverless v1 cluster, the cluster volume is always encrypted. You can choose the encryption key, but you can't disable encryption. That means that you can perform the same operations on an Aurora Serverless v1 that you can on encrypted snapshots. For more information, see Aurora Serverless v1 and snapshots.

Topics

- Scaling Aurora Serverless v1 DB cluster capacity manually
- Viewing Aurora Serverless v1 DB clusters
- Deleting an Aurora Serverless v1 DB cluster
- Aurora Serverless v1 and Aurora database engine versions

> ⚠ **Important**
>
> Aurora has two generations of serverless technology, Aurora Serverless v2 and Aurora Serverless v1. If your application can run on MySQL 8.0 or PostgreSQL 13, we recommend that you use Aurora Serverless v2. Aurora Serverless v2 scales more quickly and in a more granular way. Aurora Serverless v2 also has more compatibility with other Aurora features such as reader DB instances. Thus, if you're already familiar with Aurora, you don't have to learn as many new procedures or limitations to use Aurora Serverless v2 as with Aurora Serverless v1.
>
> You can learn about Aurora Serverless v2 in Using Aurora Serverless v2.

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and Aurora Serverless v1, see Supported Regions and Aurora DB engines for Aurora Serverless v1.

Advantages of Aurora Serverless v1

Aurora Serverless v1 provides the following advantages:

- **Simpler than provisioned –** Aurora Serverless v1 removes much of the complexity of managing DB instances and capacity.
- **Scalable –** Aurora Serverless v1 seamlessly scales compute and memory capacity as needed, with no disruption to client connections.
- **Cost-effective –** When you use Aurora Serverless v1, you pay only for the database resources that you consume, on a per-second basis.
- **Highly available storage –** Aurora Serverless v1 uses the same fault-tolerant, distributed storage system with six-way replication as Aurora to protect against data loss.

Use cases for Aurora Serverless v1

Aurora Serverless v1 is designed for the following use cases:

- **Infrequently used applications** – You have an application that is only used for a few minutes several times per day or week, such as a low-volume blog site. With Aurora Serverless v1, you pay for only the database resources that you consume on a per-second basis.
- **New applications** – You're deploying a new application and you're unsure about the instance size you need. By using Aurora Serverless v1, you can create a database endpoint and have the database autoscale to the capacity requirements of your application.
- **Variable workloads** – You're running a lightly used application, with peaks of 30 minutes to several hours a few times each day, or several times per year. Examples are applications for human resources, budgeting, and operational reporting applications. With Aurora Serverless v1, you no longer need to provision for peak or average capacity.
- **Unpredictable workloads** – You're running daily workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. With Aurora Serverless v1, your database autoscales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over.
- **Development and test databases** – Your developers use databases during work hours but don't need them on nights or weekends. With Aurora Serverless v1, your database automatically shuts down when it's not in use.
- **Multi-tenant applications** – With Aurora Serverless v1, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v1 manages individual database capacity for you.

Limitations of Aurora Serverless v1

The following limitations apply to Aurora Serverless v1:

- Aurora Serverless v1 doesn't support the following features:
  - Aurora global databases
  - Aurora Replicas
  - AWS Identity and Access Management (IAM) database authentication
  - Backtracking in Aurora
  - Database activity streams

  - Kerberos authentication
  - Performance Insights
  - RDS Proxy
  - Viewing logs in the AWS Management Console
- Connections to an Aurora Serverless v1 DB cluster are closed automatically if held open for longer than one day.
- All Aurora Serverless v1 DB clusters have the following limitations:
  - You can't export Aurora Serverless v1 snapshots to Amazon S3 buckets.
  - You can't use AWS Database Migration Service and Change Data Capture (CDC) with Aurora Serverless v1 DB clusters. Only provisioned Aurora DB clusters support CDC with AWS DMS as a source.
  - You can't save data to text files in Amazon S3 or load text file data to Aurora Serverless v1 from S3.
  - You can't attach an IAM role to an Aurora Serverless v1 DB cluster. However, you can load data to Aurora Serverless v1 from Amazon S3 by using the `aws_s3` extension with the `aws_s3.table_import_from_s3` function and the `credentials` parameter. For more information, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster.
  - When using the query editor, a Secrets Manager secret is created for the DB credentials to access the database. If you delete the credentials from the query editor, the associated secret is also deleted from Secrets Manager. You can't recover this secret after it's deleted.
- Aurora MySQL–based DB clusters running Aurora Serverless v1 don't support the following:
  - Invoking AWS Lambda functions from within your Aurora MySQL DB cluster. However, AWS Lambda functions can make calls to your Aurora Serverless v1 DB cluster.
  - Restoring a snapshot from a DB instance that isn't Aurora MySQL or RDS for MySQL.
  - Replicating data using replication based on binary logs (binlogs). This limitation is true regardless of whether your Aurora MySQL-based DB cluster Aurora Serverless v1 is the source or the target of the replication. To replicate data into an Aurora Serverless v1 DB cluster from a MySQL DB instance outside Aurora, such as one running on Amazon EC2, consider using AWS Database Migration Service. For more information, see the AWS Database Migration Service User Guide.
  - Creating users with host-based access (`'`*`username`*`'@'`*`IP_address`*`'`). This is because Aurora Serverless v1 uses a router fleet between the client and the database host for seamless scaling.

  The IP address that the Aurora Serverless DB cluster sees is that of the router host and not your client. For more information, see Aurora Serverless v1 architecture.

  Instead, use the wildcard (`'username'@'%'`).

- Aurora PostgreSQL–based DB clusters running Aurora Serverless v1 have the following limitations:
  - Aurora PostgreSQL query plan management (`apg_plan_management` extension) isn't supported.
  - The logical replication feature available in Amazon RDS PostgreSQL and Aurora PostgreSQL isn't supported.
  - Outbound communications such as those enabled by Amazon RDS for PostgreSQL extensions aren't supported. For example, you can't access external data with the `postgres_fdw/dblink` extension. For more information about RDS PostgreSQL extensions, see PostgreSQL on Amazon RDS in the *RDS User Guide*.
  - Currently, certain SQL queries and commands aren't recommended. These include session-level advisory locks, temporary relations, asynchronous notifications (`LISTEN`), and cursors with hold (`DECLARE name ... CURSOR WITH HOLD FOR query`). Also, `NOTIFY` commands prevent scaling and aren't recommended.

    For more information, see Autoscaling for Aurora Serverless v1.
- You can't set the preferred automated backup window for an Aurora Serverless v1 DB cluster.
- You can set the maintenance window for an Aurora Serverless v1 DB cluster. For more information, see Adjusting the preferred DB cluster maintenance window.

Configuration requirements for Aurora Serverless v1

When you create an Aurora Serverless v1 DB cluster, pay attention to the following requirements:

- Use these specific port numbers for each DB engine:
  - Aurora MySQL – `3306`
  - Aurora PostgreSQL – `5432`
- Create your Aurora Serverless v1 DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. When you create an Aurora Serverless v1 DB cluster in your VPC, you consume two (2) of the fifty (50) Interface and Gateway Load Balancer endpoints allotted to your VPC.

These endpoints are created automatically for you. To increase your quota, you can contact AWS Support. For more information, see Amazon VPC quotas.

- You can't give an Aurora Serverless v1 DB cluster a public IP address. You can access an Aurora Serverless v1 DB cluster only from within a VPC.
- Create subnets in different Availability Zones for the DB subnet group that you use for your Aurora Serverless v1 DB cluster. In other words, you can't have more than one subnet in the same Availability Zone.
- Changes to a subnet group used by an Aurora Serverless v1 DB cluster aren't applied to the cluster.
- You can access an Aurora Serverless v1 DB cluster from AWS Lambda. To do so, you must configure your Lambda function to run in the same VPC as your Aurora Serverless v1 DB cluster. For more information about working with AWS Lambda, see Configuring a Lambda function to access resources in an Amazon VPC in the *AWS Lambda Developer Guide*.

Using TLS/SSL with Aurora Serverless v1

By default, Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v1 DB cluster. It supports TLS/SSL versions 1.0, 1.1, and 1.2. You don't need to configure your Aurora Serverless v1 DB cluster to use TLS/SSL.

However, the following limitations apply:

- TLS/SSL support for Aurora Serverless v1 DB clusters isn't currently available in the China (Beijing) AWS Region.
- When you create database users for an Aurora MySQL–based Aurora Serverless v1 DB cluster, don't use the `REQUIRE` clause for SSL permissions. Doing so prevents users from connecting to the Aurora DB instance.
- For both MySQL Client and PostgreSQL Client utilities, session variables that you might use in other environments have no effect when using TLS/SSL between client and Aurora Serverless v1.
- For the MySQL Client, when connecting with TLS/SSL's `VERIFY_IDENTITY` mode, currently you need to use the MySQL 8.0-compatible `mysql` command. For more information, see Connecting to a DB instance running the MySQL database engine.

Depending on the client that you use to connect to Aurora Serverless v1 DB cluster, you might not need to specify TLS/SSL to get an encrypted connection. For example, to use the PostgreSQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora PostgreSQL-Compatible Edition, connect as you normally do.

```
psql -h endpoint -U user
```

After you enter your password, the PostgreSQL Client shows you see the connection details, including the TLS/SSL version and cipher.

```
psql (12.5 (Ubuntu 12.5-0ubuntu0.20.04.1), server 10.12)
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256,
 compression: off)
Type "help" for help.
```

> **Important**
>
> Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt connections by default unless SSL/TLS is disabled by the client application. The TLS/SSL connection terminates at the router fleet. Communication between the router fleet and your Aurora Serverless v1 DB cluster occurs within the service's internal network boundary.
>
> You can check the status of the client connection to examine whether the connection to Aurora Serverless v1 is TLS/SSL encrypted. The PostgreSQL `pg_stat_ssl` and `pg_stat_activity` tables and its `ssl_is_used` function don't show the TLS/SSL state for the communication between the client application and Aurora Serverless v1. Similarly, the TLS/SSL state can't be derived from the MySQL `status` statement.
>
> The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL formerly weren't supported for Aurora Serverless v1. These parameters are available now for Aurora Serverless v1. For a complete list of parameters supported by Aurora Serverless v1, call the DescribeEngineDefaultClusterParameters API operation. For more information on parameter groups and Aurora Serverless v1, see Parameter groups for Aurora Serverless v1.

To use the MySQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora MySQL-Compatible Edition, you specify TLS/SSL in your request. The following example includes the

Amazon root CA 1 trust store downloaded from Amazon Trust Services, which is necessary for this connection to succeed.

```
mysql -h endpoint -P 3306 -u user -p --ssl-ca=amazon-root-CA-1.pem --ssl-mode=REQUIRED
```

When prompted, enter your password. Soon, the MySQL monitor opens. You can confirm that the session is encrypted by using the `status` command.

```
mysql> status
--------------
mysql  Ver 14.14 Distrib 5.5.62, for Linux (x86_64) using readline 5.1
Connection id:          19
Current database:
Current user:           ***@*******
SSL:                    Cipher in use is ECDHE-RSA-AES256-SHA
...
```

To learn more about connecting to Aurora MySQL database with the MySQL Client, see Connecting to a DB instance running the MySQL database engine.

Aurora Serverless v1 supports all TLS/SSL modes available to the MySQL Client (`mysql`) and PostgreSQL Client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	mysql	psql
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the CA.	VERIFY_CA	verify-ca

Description of TLS/SSL mode	mysql	psql
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v1 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the Amazon root CA 1 trust store from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL Client:

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem
 dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres Client, see Connecting to a DB instance running the PostgreSQL database engine.

For more information about connecting to Aurora DB clusters in general, see Connecting to an Amazon Aurora DB cluster.

Supported cipher suites for connections to Aurora Serverless v1 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v1 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora MySQL DB clusters.

Aurora Serverless v1 DB clusters that are based on Aurora PostgreSQL don't support cipher suites.

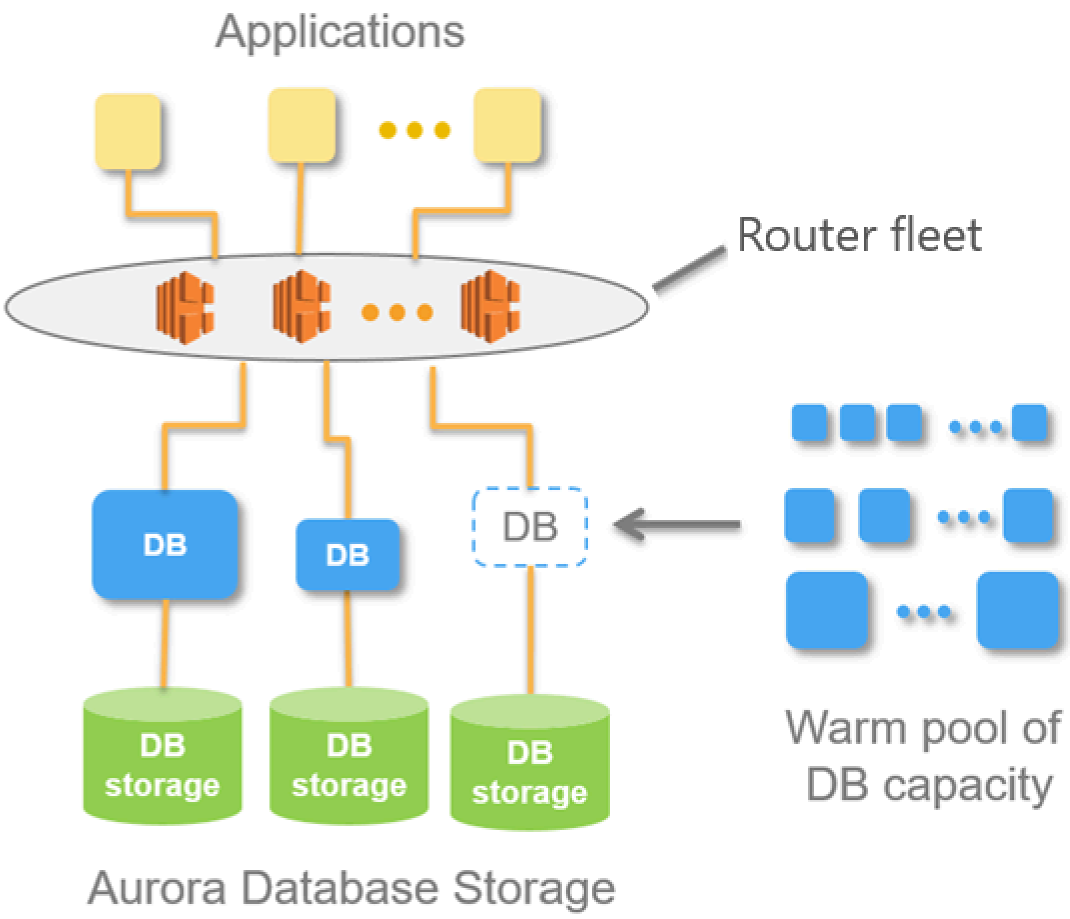
How Aurora Serverless v1 works

Following, you can learn how Aurora Serverless v1 works.

Topics

Aurora Serverless v1 architecture

The following image shows an overview of the Aurora Serverless v1 architecture.



Instead of provisioning and managing database servers, you specify Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gigabytes (GB) of memory, corresponding CPU, and networking. Database storage automatically scales from 10 gibibytes (GiB) to 128 tebibytes (TiB), the same as storage in a standard Aurora DB cluster.

You can specify the minimum and maximum ACU. The *minimum Aurora capacity unit* is the lowest ACU to which the DB cluster can scale down. The *maximum Aurora capacity unit* is the highest ACU to which the DB cluster can scale up. Based on your settings, Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory.

Aurora Serverless v1 manages the warm pool of resources in an AWS Region to minimize scaling time. When Aurora Serverless v1 adds new resources to the Aurora DB cluster, it uses the router fleet to switch active client connections to the new resources. At any specific time, you are charged only for the ACUs that are being actively used in your Aurora DB cluster.

Autoscaling for Aurora Serverless v1

The capacity allocated to your Aurora Serverless v1 DB cluster seamlessly scales up and down based on the load generated by your client application. Here, load is CPU utilization and the number of connections. When capacity is constrained by either of these, Aurora Serverless v1 scales up. Aurora Serverless v1 also scales up when it detects performance issues that can be resolved by doing so.

You can view scaling events for your Aurora Serverless v1 cluster in the AWS Management Console. During autoscaling, Aurora Serverless v1 resets the `EngineUptime` metric. The value of the reset metric value doesn't mean that seamless scaling had problems or that Aurora Serverless v1 dropped connections. It's simply the starting point for uptime at the new capacity. To learn more about metrics, see Monitoring metrics in an Amazon Aurora cluster.

When your Aurora Serverless v1 DB cluster has no active connections, it can scale down to zero capacity (0 ACUs). To learn more, see Pause and resume for Aurora Serverless v1.

When it does need to perform a scaling operation, Aurora Serverless v1 first tries to identify a *scaling point*, a moment when no queries are being processed. Aurora Serverless v1 might not be able to find a scaling point for the following reasons:

- Long-running queries
- In-progress transactions
- Temporary tables or table locks

To increase your Aurora Serverless v1 DB cluster's success rate when finding a scaling point, we recommend that you avoid long-running queries and long-running transactions. To learn more about operations that block scaling and how to avoid them, see Best practices for working with Aurora Serverless v1.

By default, Aurora Serverless v1 tries to find a scaling point for 5 minutes (300 seconds). You can specify a different timeout period when you create or modify the cluster. The timeout period can be between 60 seconds and 10 minutes (600 seconds). If Aurora Serverless v1 can't find a scaling point within the specified period, the autoscaling operation times out.

By default, if autoscaling doesn't find a scaling point before timing out, Aurora Serverless v1 keeps the cluster at the current capacity. You can change this default behavior when you create or modify your Aurora Serverless v1 DB cluster by selecting the **Force the capacity change** option. For more information, see Timeout action for capacity changes.

Timeout action for capacity changes

If autoscaling times out without finding a scaling point, by default Aurora keeps the current capacity. You can choose to have Aurora force the change by selecting the **Force the capacity change** option. This option is available in the **Autoscaling timeout and action** section of the **Create database** page when you create the cluster.

By default, the **Force the capacity change** option isn't selected. Keep this option clear to have your Aurora Serverless v1 DB cluster's capacity remain unchanged if the scaling operation times out without finding a scaling point.

Selecting this option causes your Aurora Serverless v1 DB cluster to enforce the capacity change, even without a scaling point. Before selecting this option, be aware of the consequences of this selection:

- Any in-process transactions are interrupted, and the following error message appears.

  Aurora MySQL version 2 – ERROR 1105 (HY000): The last transaction was aborted due to Seamless Scaling. Please retry.

  You can resubmit the transactions as soon as your Aurora Serverless v1 DB cluster is available.
- Connections to temporary tables and locks are dropped.

  We recommend that you select the **Force the capacity change** option only if your application can recover from dropped connections or incomplete transactions.

The choices that you make in the AWS Management Console when you create an Aurora Serverless v1 DB cluster are stored in the `ScalingConfigurationInfo` object, in the `SecondsBeforeTimeout` and `TimeoutAction` properties. The value of the `TimeoutAction` property is set to one of the following values when you create your cluster:

- `RollbackCapacityChange` – This value is set when you select the **Roll back the capacity change** option. This is the default behavior.
- `ForceApplyCapacityChange` – This value is set when you select the **Force the capacity change** option.

You can get the value of this property on an existing Aurora Serverless v1 DB cluster by using the describe-db-clusters AWS CLI command, as shown following.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters --region region \
  --db-cluster-identifier your-cluster-name \
  --query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'
```

For Windows:

```
aws rds describe-db-clusters --region region ^
  --db-cluster-identifier your-cluster-name ^
  --query "*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}"
```

As an example, the following shows the query and response for an Aurora Serverless v1 DB cluster named `west-coast-sles` in the US West (N. California) Region.

```
$ aws rds describe-db-clusters --region us-west-1 --db-cluster-identifier west-coast-
sles
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'

[
    {
        "ScalingConfigurationInfo": {
            "MinCapacity": 1,
            "MaxCapacity": 64,
            "AutoPause": false,
            "SecondsBeforeTimeout": 300,
            "SecondsUntilAutoPause": 300,
            "TimeoutAction": "RollbackCapacityChange"
        }
    }
]
```

As the response shows, this Aurora Serverless v1 DB cluster uses the default setting.

For more information, see Creating an Aurora Serverless v1 DB cluster. After creating your Aurora Serverless v1, you can modify the timeout action and other capacity settings at any time. To learn how, see Modifying an Aurora Serverless v1 DB cluster.

Pause and resume for Aurora Serverless v1

You can choose to pause your Aurora Serverless v1 DB cluster after a given amount of time with no activity. You specify the amount of time with no activity before the DB cluster is paused. When you select this option, the default inactivity time is five minutes, but you can change this value. This is an optional setting.

When the DB cluster is paused, no compute or memory activity occurs, and you are charged only for storage. If database connections are requested when an Aurora Serverless v1 DB cluster is paused, the DB cluster automatically resumes and services the connection requests.

When the DB cluster resumes activity, it has the same capacity as it had when Aurora paused the cluster. The number of ACUs depends on how much Aurora scaled the cluster up or down before pausing it.

> **Note**
>
> If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, Aurora restores the DB cluster from the snapshot when there is a request to connect to it.

Determining the maximum number of database connections for Aurora Serverless v1

The following examples are for an Aurora Serverless v1 DB cluster that's compatible with MySQL 5.7. You can use a MySQL client or the query editor, if you've configured access to it. For more information, see Running queries in the query editor.

To find the maximum number of database connections

1. Find the capacity range for your Aurora Serverless v1 DB cluster using the AWS CLI.

```
aws rds describe-db-clusters \
    --db-cluster-identifier my-serverless-57-cluster \
    --query 'DBClusters[*].ScalingConfigurationInfo|[0]'
```

   The result shows that its capacity range is 1–4 ACUs.

```
{
    "MinCapacity": 1,
    "AutoPause": true,
    "MaxCapacity": 4,
    "TimeoutAction": "RollbackCapacityChange",
    "SecondsUntilAutoPause": 3600
}
```

2. Run the following SQL query to find the maximum number of connections.

   ```
   select @@max_connections;
   ```

   The result shown is for the minimum capacity of the cluster, 1 ACU.

   ```
   @@max_connections
   90
   ```

3. Scale the cluster to 8–32 ACUs.

   For more information on scaling, see Modifying an Aurora Serverless v1 DB cluster.

4. Confirm the capacity range.

   ```
   {
       "MinCapacity": 8,
       "AutoPause": true,
       "MaxCapacity": 32,
       "TimeoutAction": "RollbackCapacityChange",
       "SecondsUntilAutoPause": 3600
   }
   ```

5. Find the maximum number of connections.

   ```
   select @@max_connections;
   ```

   The result shown is for the minimum capacity of the cluster, 8 ACUs.

   ```
   @@max_connections
   1000
   ```

6. Scale the cluster to the maximum possible, 256–256 ACUs.

7. Confirm the capacity range.

   ```
   {
       "MinCapacity": 256,
       "AutoPause": true,
   ```

```
    "MaxCapacity": 256,
    "TimeoutAction": "RollbackCapacityChange",
    "SecondsUntilAutoPause": 3600
}
```

8. Find the maximum number of connections.

   ```
   select @@max_connections;
   ```

   The result shown is for 256 ACUs.

   ```
   @@max_connections
   6000
   ```

   > **Note**
   >
   > The `max_connections` value doesn't scale linearly with the number of ACUs.

9. Scale the cluster back down to 1–4 ACUs.

   ```
   {
       "MinCapacity": 1,
       "AutoPause": true,
       "MaxCapacity": 4,
       "TimeoutAction": "RollbackCapacityChange",
       "SecondsUntilAutoPause": 3600
   }
   ```

   This time, the `max_connections` value is for 4 ACUs.

   ```
   @@max_connections
   270
   ```

10. Let the cluster scale down to 2 ACUs.

    ```
    @@max_connections
    180
    ```

    If you've configured the cluster to pause after a certain amount of time idle, it scales down to 0 ACUs. However, `max_connections` doesn't drop below the value for 1 ACU.

```
@@max_connections
90
```

Parameter groups for Aurora Serverless v1

When you create your Aurora Serverless v1 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. Unlike provisioned Aurora DB clusters, an Aurora Serverless v1 DB cluster has a single read/write DB instance that's configured with a DB cluster parameter group only—it doesn't have a separate DB parameter group. During autoscaling, Aurora Serverless v1 needs to be able to change parameters for the cluster to work best for the increased or decreased capacity. Thus, with an Aurora Serverless v1 DB cluster, some of the changes that you might make to parameters for a particular DB engine type might not apply.

For example, an Aurora PostgreSQL–based Aurora Serverless v1 DB cluster can't use `apg_plan_mgmt.capture_plan_baselines` and other parameters that might be used on provisioned Aurora PostgreSQL DB clusters for query plan management.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the describe-engine-default-cluster-parameters CLI command and querying the AWS Region. The following are values that you can use for the `--db-parameter-group-family` option.

Aurora MySQL version 2	`aurora-mysql5.7`
Aurora PostgreSQL version 11	`aurora-postgresql11`
Aurora PostgreSQL version 13	`aurora-postgresql13`

We recommend that you configure your AWS CLI with your AWS access key ID and AWS secret access key, and that you set your AWS Region before using AWS CLI commands. Providing the Region to your CLI configuration saves you from entering the `--region` parameter when running commands. To learn more about configuring AWS CLI, see Configuration basics in the *AWS Command Line Interface User Guide*.

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 2.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-cluster-parameters \
  --db-parameter-group-family aurora-mysql5.7 --query \
  'EngineDefaults.Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, `serverless`) == `true`] | [*].{param:ParameterName}' \
  --output text
```

For Windows:

```
aws rds describe-engine-default-cluster-parameters ^
   --db-parameter-group-family aurora-mysql5.7 --query ^
   "EngineDefaults.Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, 'serverless') == `true`] | [*].{param:ParameterName}" ^
   --output text
```

Modifying parameter values for Aurora Serverless v1

As explained in Working with parameter groups, you can't directly change values in a default parameter group, regardless of its type (DB cluster parameter group, DB parameter group). Instead, you create a custom parameter group based on the default DB cluster parameter group for your Aurora DB engine and change settings as needed on that parameter group. For example, you might want to change some of the settings for your Aurora Serverless v1 DB cluster to log queries or to upload DB engine specific logs to Amazon CloudWatch.

To create a custom DB cluster parameter group

1. Sign in to the AWS Management Console and then open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Parameter groups**.
3. Choose **Create parameter group** to open the Parameter group details pane.
4. Choose the appropriate default DB cluster group for the DB engine you want to use for your Aurora Serverless v1 DB cluster. Be sure that you choose the following options:

   a. For **Parameter group family**, choose the appropriate family for your chosen DB engine. Be sure that your choice has the prefix `aurora-` in its name.

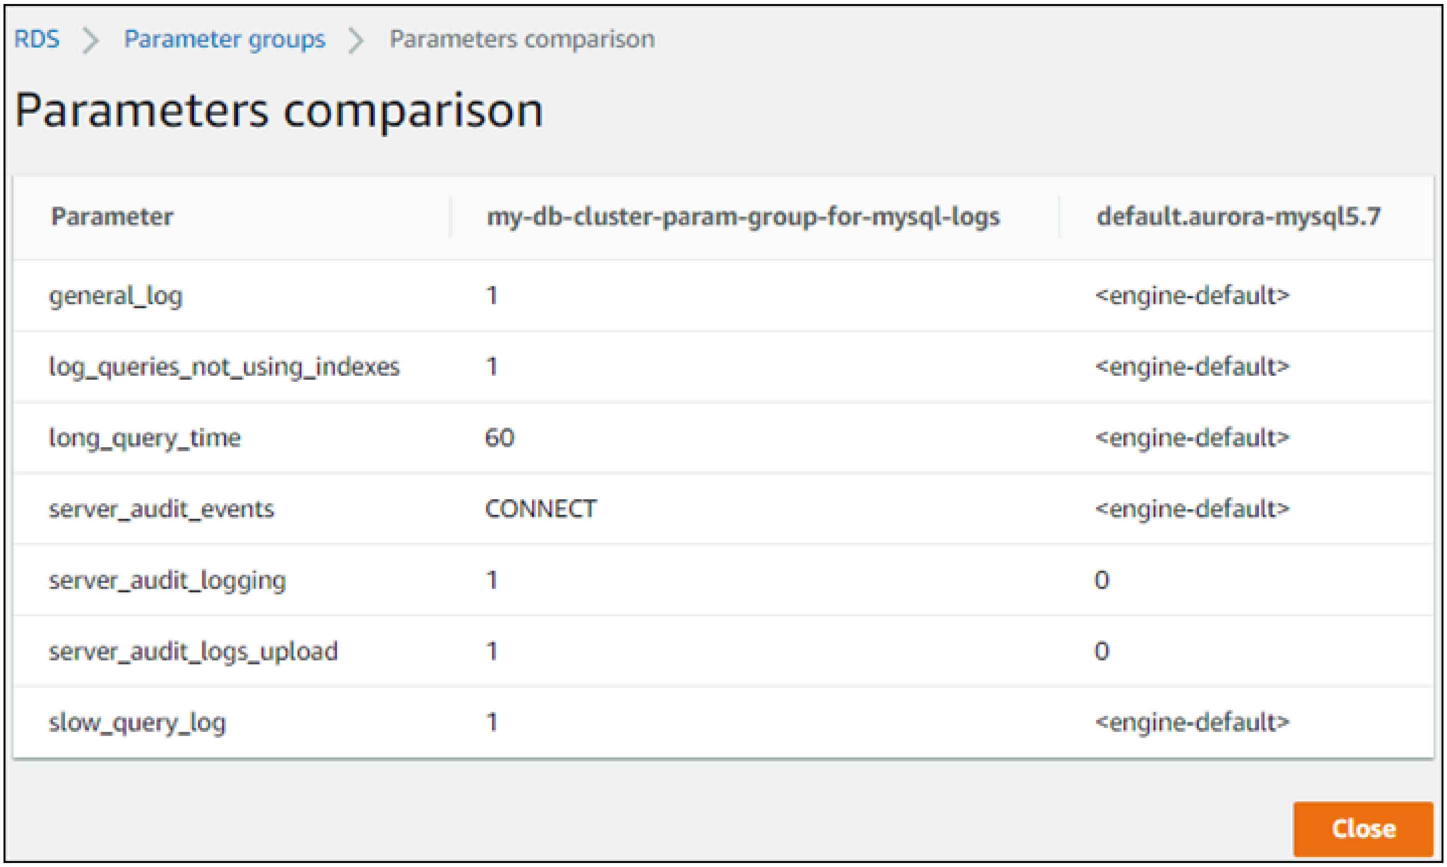
   b. For **Type**, choose **DB Cluster Parameter Group**.

c. For **Group name** and **Description**, enter meaningful names for you or others who might need to work with your Aurora Serverless v1 DB cluster and its parameters.

d. Choose **Create**.

Your custom DB cluster parameter group is added to the list of parameter groups available in your AWS Region. You can use your custom DB cluster parameter group when you create new Aurora Serverless v1 DB clusters. You can also modify an existing Aurora Serverless v1 DB cluster to use your custom DB cluster parameter group. After your Aurora Serverless v1 DB cluster starts using your custom DB cluster parameter group, you can change values for dynamic parameters using either the AWS Management Console or the AWS CLI.

You can also use the console to view a side-by-side comparison of the values in your custom DB cluster parameter group compared to the default DB cluster parameter group, as shown in the following screenshot.



Parameters comparison

Parameter	my-db-cluster-param-group-for-mysql-logs	default.aurora-mysql5.7
general_log	1	<engine-default>
log_queries_not_using_indexes	1	<engine-default>
long_query_time	60	<engine-default>
server_audit_events	CONNECT	<engine-default>
server_audit_logging	1	0
server_audit_logs_upload	1	0
slow_query_log	1	<engine-default>

When you change parameter values on an active DB cluster, Aurora Serverless v1 starts a seamless scale in order to apply the parameter changes. If your Aurora Serverless v1 DB cluster is in a paused state, it resumes and starts scaling so that it can make the change. The scaling operation for a parameter group change always forces a capacity change, so be aware that modifying parameters might result in dropped connections if a scaling point can't be found during the scaling period.

Logging for Aurora Serverless v1

By default, error logs for Aurora Serverless v1 are enabled and automatically uploaded to Amazon CloudWatch. You can also have your Aurora Serverless v1 DB cluster upload Aurora database-engine specific logs to CloudWatch. To do this, enable configuration parameters in your custom DB cluster parameter group. Your Aurora Serverless v1 DB cluster then uploads all available logs to Amazon CloudWatch. At this point, you can use CloudWatch to analyze log data, create alarms, and view metrics.

For Aurora MySQL, the following table shows the logs that you can enable. When enabled, they're automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch.

Aurora MySQL log	Description
`general_log`	Creates the general log. Set to 1 to turn on. Default is off (0).
`log_queries_not_using_indexes`	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
`long_query_time`	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 3,1536,000. Default is 0 (not active).
`server_audit_events`	The list of events to capture in the logs. Supported values are `CONNECT`, `QUERY`, `QUERY_DCL` , `QUERY_DDL` , `QUERY_DML` , and `TABLE`.
`server_audit_logging`	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the `server_audit_events` parameter.

Aurora MySQL log	Description
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

For Aurora PostgreSQL, the following table shows the logs that you can enable. When enabled, they're automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch along with the regular error logs.

Aurora PostgreSQL log	Description
log_connections	Turned on by default and can't be changed. It logs details for all new client connections.
log_disconnections	Turned on by default and can't be changed. Logs all client disconnections.
log_hostname	Turned off by default and can't be changed. Hostnames aren't logged.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).

Aurora PostgreSQL log	Description
`log_statement`	Controls the specific SQL statements that get logged. Supported values are none, `ddl`, `mod`, and `all`. Default is none.

After you turn on logs for Aurora MySQL or Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can view the logs in CloudWatch.

Viewing Aurora Serverless v1 logs with Amazon CloudWatch

Aurora Serverless v1 automatically uploads ("publishes") to Amazon CloudWatch all logs that are enabled in your custom DB cluster parameter group. You don't need to choose or specify the log types. Uploading logs starts as soon as you enable the log configuration parameter. If you later disable the log parameter, further uploads stop. However, all the logs that have already been published to CloudWatch remain until you delete them.

For more information on using CloudWatch with Aurora MySQL logs, see Monitoring log events in Amazon CloudWatch.

For more information about CloudWatch and Aurora PostgreSQL, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.

To view logs for your Aurora Serverless v1 DB cluster

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose your AWS Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v1 DB cluster log from the list. For error logs, the naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/error
```

For example, in the following screenshot you can find listings for logs published for an Aurora PostgreSQL Aurora Serverless v1 DB cluster named `western-sles`. You can also find several listings for Aurora MySQL Aurora Serverless v1 DB cluster, `west-coast-sles`. Choose the log that you're interest in to start exploring its content.

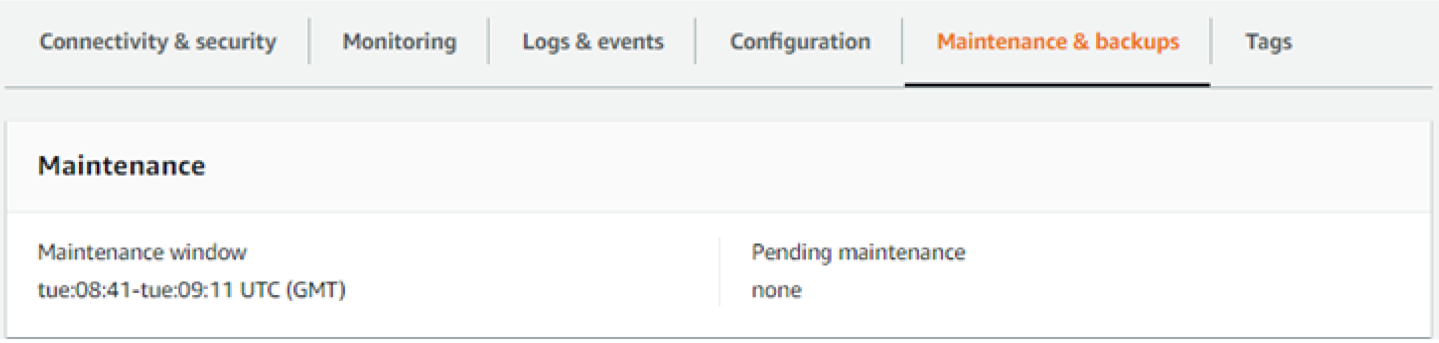
Log groups (5)

By default, we only load up to 10000 log groups.

□	Log group ▲	Retention ▽	Metric filters ▽	Contributor Insights ▽
□	/aws/rds/cluster/west-coast-sles/audit	Never expire	-	-
□	/aws/rds/cluster/west-coast-sles/error	Never expire	-	-
□	/aws/rds/cluster/west-coast-sles/general	Never expire	-	-
□	/aws/rds/cluster/western-sles/postgresql	Never expire	-	-

Aurora Serverless v1 and maintenance

Maintenance for Aurora Serverless v1 DB cluster, such as applying the latest features, fixes, and security updates, is performed automatically for you. Aurora Serverless v1 has a maintenance window that you can view in the AWS Management Console in **Maintenance & backups** for your Aurora Serverless v1 DB cluster. You can find the date and time that maintenance might be performed and if any maintenance is pending for your Aurora Serverless v1 DB cluster, as shown in the following figure.



Maintenance

Maintenance window
tue:08:41-tue:09:11 UTC (GMT)

Pending maintenance
none

You can set the maintenance window when you create the Aurora Serverless v1 DB cluster, and you can modify the window later. For more information, see Adjusting the preferred DB cluster maintenance window.

Maintenance windows are used for scheduled major version upgrades. Minor version upgrades and patches are applied immediately during scaling. Scaling happens according to your setting for `TimeoutAction`:

- `ForceApplyCapacityChange` – The change is applied immediately.
- `RollbackCapacityChange` – Aurora forcibly updates the cluster after 3 days from the first patch attempt.

As with any change that's forced without an appropriate scaling point, this might interrupt your workload.

Whenever possible, Aurora Serverless v1 performs maintenance in a nondisruptive manner. When maintenance is required, your Aurora Serverless v1 DB cluster scales its capacity to handle the necessary operations. Before scaling, Aurora Serverless v1 looks for a scaling point. It does so for up to three days if necessary.

At the end of each day that Aurora Serverless v1 can't find a scaling point, it creates a cluster event. This event notifies you of the pending maintenance and the need to scale to perform maintenance. The notification includes the date when Aurora Serverless v1 can force the DB cluster to scale.

For more information, see Timeout action for capacity changes.

Aurora Serverless v1 and failover

If the DB instance for an Aurora Serverless v1 DB cluster becomes unavailable or the Availability Zone (AZ) it's in fails, Aurora recreates the DB instance in a different AZ. However, the Aurora Serverless v1 cluster isn't a Multi-AZ cluster. That's because it consists of a single DB instance in a single AZ. Thus, this failover mechanism takes longer than for an Aurora cluster with provisioned or Aurora Serverless v2 instances. The Aurora Serverless v1 failover time is undefined because it depends on demand and capacity availability in other AZs within the given AWS Region.

Because Aurora separates computation capacity and storage, the storage volume for the cluster is spread across multiple AZs. Your data remains available even if outages affect the DB instance or the associated AZ.

Aurora Serverless v1 and snapshots

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. To copy or share a snapshot of an Aurora Serverless v1 cluster, encrypt the snapshot using your own AWS KMS key. For more information, see Copying a DB cluster snapshot. To learn more about encryption and Amazon Aurora, see Encrypting an Amazon Aurora DB cluster

Creating an Aurora Serverless v1 DB cluster

The following procedure creates an Aurora Serverless v1 cluster without any of your schema objects or data. If you want to create an Aurora Serverless v1 cluster that's a duplicate of an existing provisioned or Aurora Serverless v1 cluster, you can perform a snapshot restore or cloning operation instead. For those details, see Restoring from a DB cluster snapshot and Cloning a volume for an Amazon Aurora DB cluster. You can't convert an existing provisioned cluster to Aurora Serverless v1. You also can't convert an existing Aurora Serverless v1 cluster back to a provisioned cluster.

When you create an Aurora Serverless v1 DB cluster, you can set the minimum and maximum capacity for the cluster. A capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless v1 creates scaling rules for thresholds for CPU utilization, connections, and available memory and seamlessly scales to a range of capacity units as needed for your applications. For more information see Aurora Serverless v1 architecture.

You can set the following specific values for your Aurora Serverless v1 DB cluster:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.

You can also choose the following optional scaling configuration options:

- **Force scaling the capacity to the specified values when the timeout is reached** – You can choose this setting if you want Aurora Serverless v1 to force Aurora Serverless v1 to scale even if it can't find a scaling point before it times out. If you want Aurora Serverless v1 to cancel capacity changes if it can't find a scaling point, don't choose this setting. For more information, see Timeout action for capacity changes.
- **Pause compute capacity after consecutive minutes of inactivity** – You can choose this setting if you want Aurora Serverless v1 to scale to zero when there's no activity on your DB cluster for an amount of time you specify. With this setting enabled, your Aurora Serverless v1 DB cluster automatically resumes processing and scales to the necessary capacity to handle the workload when database traffic resumes. To learn more, see Pause and resume for Aurora Serverless v1.

Before you can create an Aurora Serverless v1 DB cluster, you need an AWS account. You also need to have completed the setup tasks for working with Amazon Aurora. For more information, see Setting up your environment for Amazon Aurora. You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see Creating an Amazon Aurora DB cluster.

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see Supported Regions and Aurora DB engines for Aurora Serverless v1.

> **Note**
>
> The cluster volume for an Aurora Serverless v1 cluster is always encrypted. When you create your Aurora Serverless v1 DB cluster, you can't turn off encryption, but you can choose to use your own encryption key. With Aurora Serverless v2, you can choose whether to encrypt the cluster volume.

You can create an Aurora Serverless v1 DB cluster with the AWS Management Console, the AWS CLI, or the RDS API.

> **Note**
>
> If you receive the following error message when trying to create your cluster, your account needs additional permissions.
>
> `Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.`
>
> See Using service-linked roles for Amazon Aurora for more information.

You can't directly connect to the DB instance on your Aurora Serverless v1 DB cluster. To connect to your Aurora Serverless v1 DB cluster, you use the database endpoint. You can find the endpoint for your Aurora Serverless v1 DB cluster on the **Connectivity & security** tab for your cluster in the AWS Management Console. For more information, see Connecting to an Amazon Aurora DB cluster.

Console

Use the following general procedure. For more information on creating an Aurora DB cluster using the AWS Management Console, see Creating an Amazon Aurora DB cluster.

To create a new Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console.
2. Choose an AWS Region that supports Aurora Serverless v1.
3. Choose Amazon RDS from the AWS Services list.
4. Choose **Create database**.
5. On the **Create database** page:

   a. Choose **Standard create** for the database creation method.

   b. Continue creating the Aurora Serverless v1 DB cluster by using the steps from the following examples.

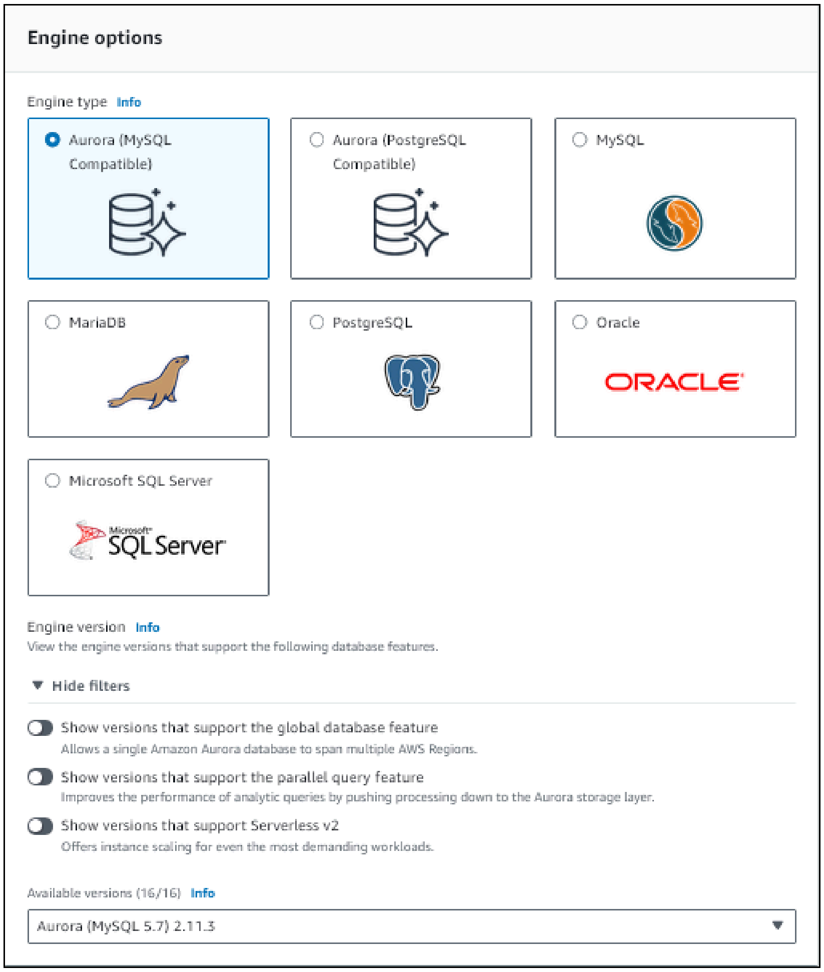
   > **Note**
   >
   > If you choose a version of the DB engine that doesn't support Aurora Serverless v1, the **Serverless** option doesn't display for **DB instance class**.

Example for Aurora MySQL

Use the following procedure.

To create an Aurora Serverless v1 DB cluster for Aurora MySQL

1. For **Engine type**, choose **Aurora (MySQL Compatibile)**.
2. Choose the Aurora MySQL version, compatible with Aurora Serverless v1, that you want for your DB cluster. The supported versions are shown on the right side of the page.



Engine options

Engine type Info

● Aurora (MySQL Compatible)

○ Aurora (PostgreSQL Compatible)

○ MySQL

○ MariaDB

○ PostgreSQL

○ Oracle

○ Microsoft SQL Server

Engine version Info
View the engine versions that support the following database features.

▼ Hide filters

Show versions that support the global database feature
Allows a single Amazon Aurora database to span multiple AWS Regions.

Show versions that support the parallel query feature
Improves the performance of analytic queries by pushing processing down to the Aurora storage layer.

Show versions that support Serverless v2
Offers instance scaling for even the most demanding workloads.

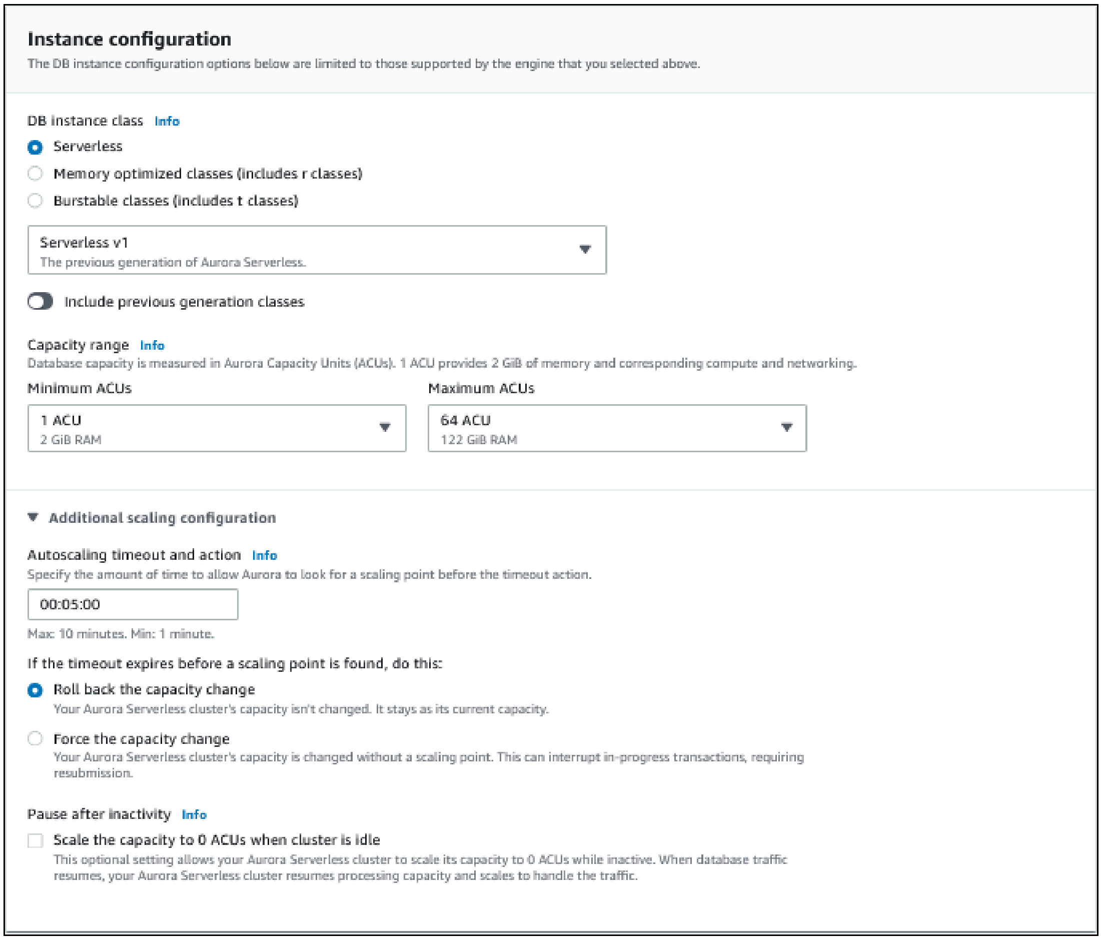
Available versions (16/16) Info

Aurora (MySQL 5.7) 2.11.3 ▼

3. For **DB instance class**, choose **Serverless**.

4. Set the **Capacity range** for the DB cluster.

5. Adjust values as needed in the **Additional scaling configuration** section of the page. To learn more about capacity settings, see Autoscaling for Aurora Serverless v1.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

Serverless v1
The previous generation of Aurora Serverless.

Include previous generation classes

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
1 ACU 2 GiB RAM	64 ACU 122 GiB RAM

▼ Additional scaling configuration

Autoscaling timeout and action Info

Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.

00:05:00

Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

● Roll back the capacity change
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

○ Force the capacity change
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

Pause after inactivity Info

□ Scale the capacity to 0 ACUs when cluster is idle
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

6. To enable the Data API for your Aurora Serverless v1 DB cluster, select the **Data API** check box under **Additional configuration** in the **Connectivity** section.

   To learn more about the Data API, see Using RDS Data API.

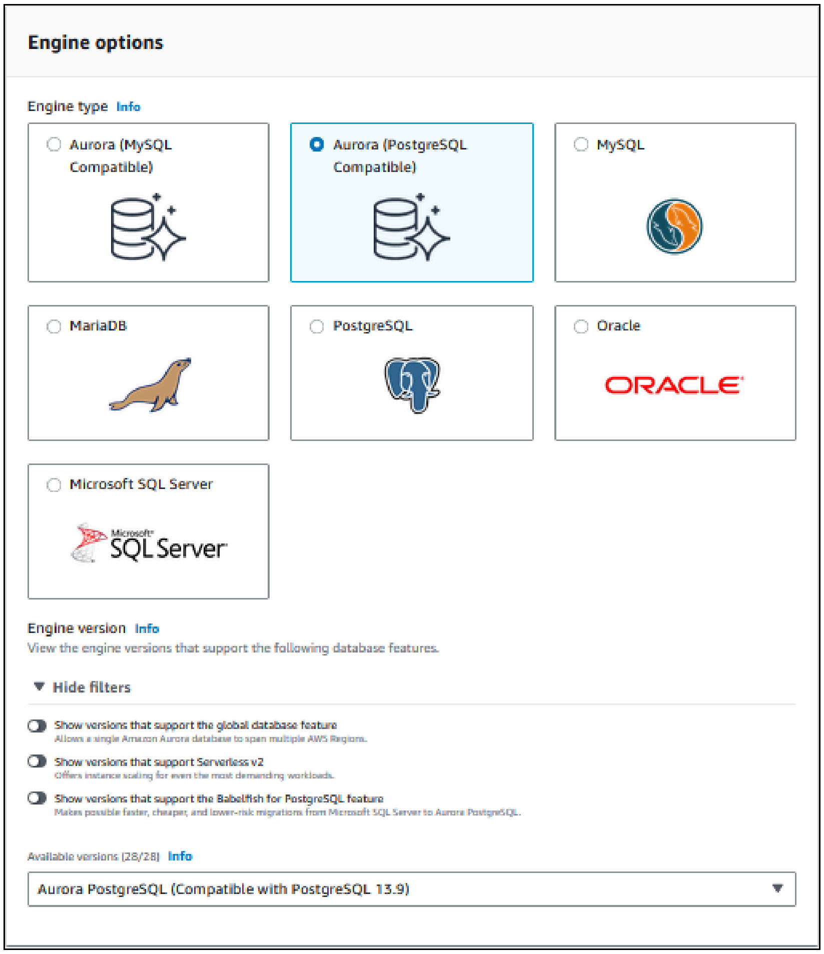
7. Choose other database settings as needed, then choose **Create database.**

Example for Aurora PostgreSQL

Use the following procedure.

To create an Aurora Serverless v1 DB cluster for Aurora PostgreSQL

1. For **Engine type**, choose **Aurora (PostgreSQL Compatibile)**.
2. Choose the Aurora PostgreSQL version, compatible with Aurora Serverless v1, that you want for your DB cluster. The supported versions are shown on the right side of the page.



Engine options

Engine type Info

○ Aurora (MySQL Compatible)

● Aurora (PostgreSQL Compatible)

○ MySQL

▼ Hide filters

○ Show versions that support the global database feature
Allows a single Amazon Aurora database to span multiple AWS Regions.

○ Show versions that support Serverless v2
Offers instance scaling for even the most demanding workloads.

○ Show versions that support the Babelfish for PostgreSQL feature
Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

Available versions (28/28) Info

Aurora PostgreSQL (Compatible with PostgreSQL 13.9) ▼

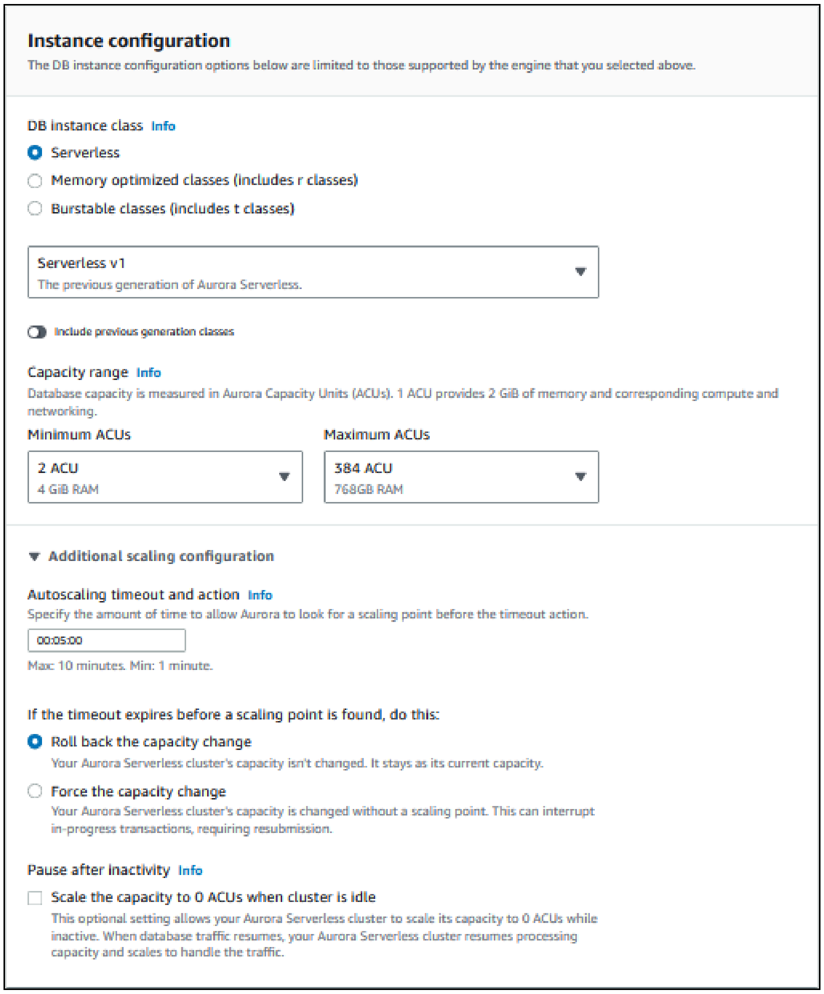
3. For **DB instance class**, choose **Serverless**.

4. If you chose an Aurora PostgreSQL version 13 minor version, choose **Serverless v1** from the menu.

> **Note**
>
> Aurora PostgreSQL version 13 also supports Aurora Serverless v2.

5. Set the **Capacity range** for the DB cluster.

6. Adjust values as needed in the **Additional scaling configuration** section of the page. To learn more about capacity settings, see Autoscaling for Aurora Serverless v1.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

Serverless v1
The previous generation of Aurora Serverless.

Include previous generation classes

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs: 2 ACU, 4 GiB RAM

Maximum ACUs: 384 ACU, 768GB RAM

▼ Additional scaling configuration

Autoscaling timeout and action Info

Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.

00:05:00

Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

● Roll back the capacity change
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

○ Force the capacity change
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

Pause after inactivity Info

□ Scale the capacity to 0 ACUs when cluster is idle
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

7. To use the Data API with your Aurora Serverless v1 DB cluster, select the **Data API** check box under **Additional configuration** in the **Connectivity** section.

   To learn more about the Data API, see Using RDS Data API.

8. Choose other database settings as needed, then choose **Create database.**

AWS CLI

To create a new Aurora Serverless v1 DB cluster with the AWS CLI, run the create-db-cluster command and specify `serverless` for the `--engine-mode` option.

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections.

The following command examples create a new Serverless DB cluster by setting the `--engine-mode` option to `serverless`. The examples also specify values for the `--scaling-configuration` option.

Example for Aurora MySQL

The following command creates a new Aurora MySQL–compatible Serverless DB cluster. Valid capacity values for Aurora MySQL are 1, 2, 4, 8, 16, 32, 64, 128, and 256.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.4 \
    --engine-mode serverless \
    --scaling-configuration
 MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
    --master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster ^
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.4 ^
    --engine-mode serverless ^
    --scaling-configuration
 MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^
    --master-username username --master-user-password password
```

Example for Aurora PostgreSQL

The following command creates a new PostgreSQL 13.9–compatible Serverless DB cluster. Valid capacity values for Aurora PostgreSQL are 2, 4, 8, 16, 32, 64, 192, and 384.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
    --engine aurora-postgresql --engine-version 13.9 \
    --engine-mode serverless \
    --scaling-configuration
 MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true \
    --master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster ^
    --engine aurora-postgresql --engine-version 13.9 ^
    --engine-mode serverless ^
    --scaling-configuration
 MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true ^
    --master-username username --master-user-password password
```

RDS API

To create a new Aurora Serverless v1 DB cluster with the RDS API, run the CreateDBCluster operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Restoring an Aurora Serverless v1 DB cluster

You can configure an Aurora Serverless v1 DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless v1 DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see Timeout action for capacity changes.

- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

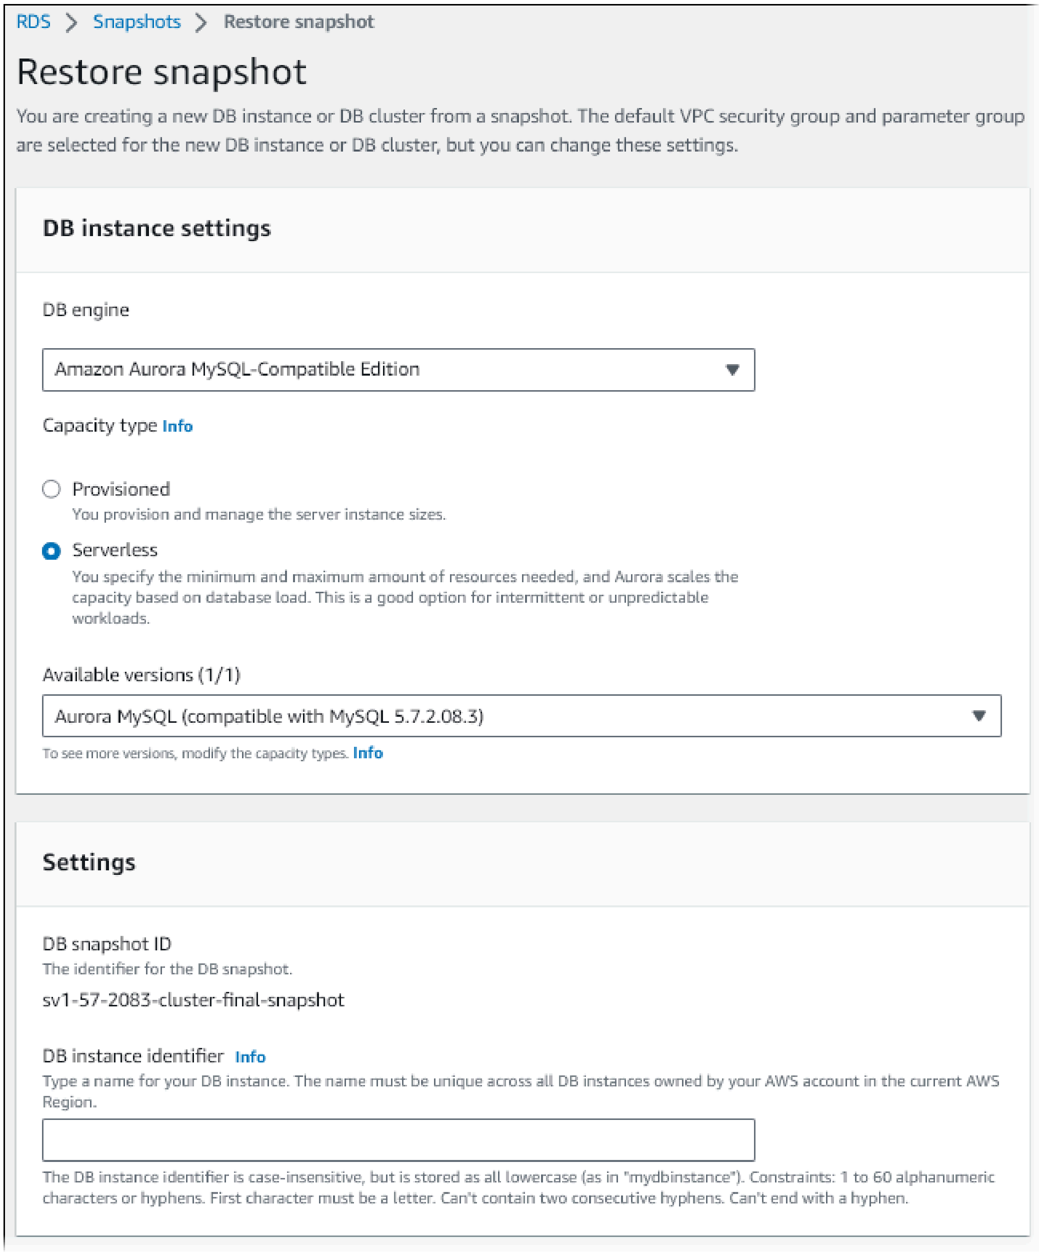
For general information about restoring a DB cluster from a snapshot, see Restoring from a DB cluster snapshot.

Console

You can restore a DB cluster snapshot to an Aurora DB cluster with the AWS Management Console.

To restore a DB cluster snapshot to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose **Snapshots**, and choose the DB cluster snapshot that you want to restore.
4. For **Actions**, choose **Restore Snapshot**.
5. On the **Restore DB Cluster** page, choose **Serverless** for **Capacity type**.



RDS > Snapshots > Restore snapshot

Restore snapshot

You are creating a new DB instance or DB cluster from a snapshot. The default VPC security group and parameter group are selected for the new DB instance or DB cluster, but you can change these settings.

DB instance settings

DB engine

Amazon Aurora MySQL-Compatible Edition

Capacity type Info

○ Provisioned
You provision and manage the server instance sizes.

● Serverless
You specify the minimum and maximum amount of resources needed, and Aurora scales the capacity based on database load. This is a good option for intermittent or unpredictable workloads.

Available versions (1/1)

Aurora MySQL (compatible with MySQL 5.7.2.08.3)

To see more versions, modify the capacity types. Info

Settings

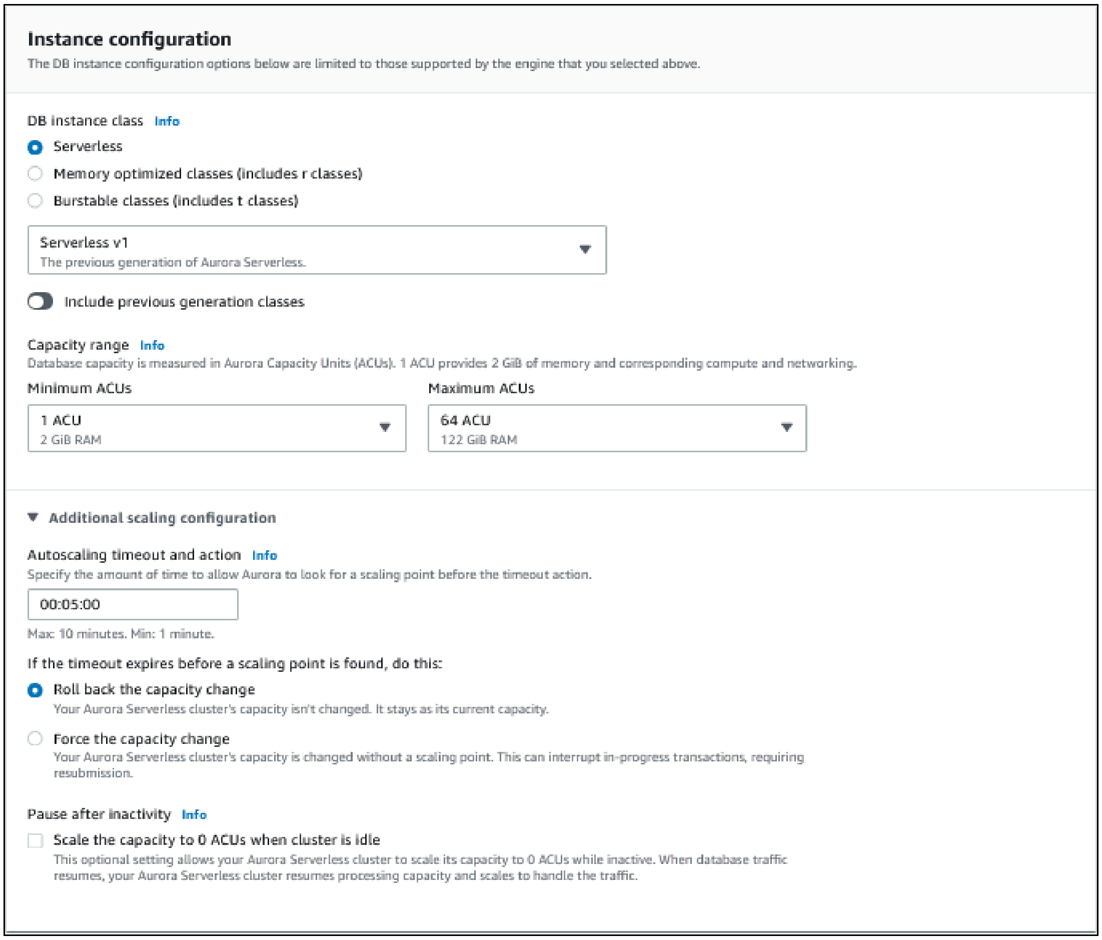
DB snapshot ID
The identifier for the DB snapshot.
sv1-57-2083-cluster-final-snapshot

DB instance identifier Info
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

6. In the **DB cluster identifier** field, type the name for your restored DB cluster, and complete the other fields.

7. In the **Capacity settings** section, modify the scaling configuration.



Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class Info

● Serverless

○ Memory optimized classes (includes r classes)

○ Burstable classes (includes t classes)

Serverless v1
The previous generation of Aurora Serverless.

Include previous generation classes

Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs: 1 ACU, 2 GiB RAM

Maximum ACUs: 64 ACU, 122 GiB RAM

▼ Additional scaling configuration

Autoscaling timeout and action Info

Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.

00:05:00

Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

● Roll back the capacity change
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

○ Force the capacity change
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

Pause after inactivity Info

□ Scale the capacity to 0 ACUs when cluster is idle
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

8. Choose **Restore DB Cluster**.

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For details, see the instructions in Connecting to an Amazon Aurora DB cluster.

Note

If you encounter the following error message, your account requires additional permissions: `Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.` For more information, see Using service-linked roles for Amazon Aurora.

AWS CLI

You can configure an Aurora Serverless DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see Timeout action for capacity changes.
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

> **Note**
>
> The version of the DB cluster snapshot must be compatible with Aurora Serverless v1. For the list of supported versions, see Supported Regions and Aurora DB engines for Aurora Serverless v1.

To restore a snapshot to an Aurora Serverless v1 cluster with MySQL 5.7 compatibility, include the following additional parameters:

- `--engine` **`aurora-mysql`**
- `--engine-version` **`5.7`**

The `--engine` and `--engine-version` parameters let you create a MySQL 5.7-compatible Aurora Serverless v1 cluster from a MySQL 5.6-compatible Aurora or Aurora Serverless v1 snapshot. The following example restores a snapshot from a MySQL 5.6-compatible cluster named *`mydbclustersnapshot`* to a MySQL 5.7-compatible Aurora Serverless v1 cluster named *`mynewdbcluster`*.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
    --db-cluster-identifier mynewdbcluster \
    --snapshot-identifier mydbclustersnapshot \
    --engine-mode serverless \
    --engine aurora-mysql \
    --engine-version 5.7
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
    --db-instance-identifier mynewdbcluster ^
    --db-snapshot-identifier mydbclustersnapshot ^
    --engine aurora-mysql ^
    --engine-version 5.7
```

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In the following example, you restore from a previously created DB cluster snapshot named *mydbclustersnapshot* to a new DB cluster named *mynewdbcluster*. You set the `--scaling-configuration` so that the new Aurora Serverless v1 DB cluster can scale from 8 ACUs to 64 ACUs (Aurora capacity units) as needed to process the workload. After processing completes and after 1000 seconds with no connections to support, the cluster shuts down until connection requests prompt it to restart.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
    --db-cluster-identifier mynewdbcluster \
    --snapshot-identifier mydbclustersnapshot \
    --engine-mode serverless --scaling-configuration
 MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=10
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
    --db-instance-identifier mynewdbcluster ^
    --db-snapshot-identifier mydbclustersnapshot ^
    --engine-mode serverless --scaling-configuration
 MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=10
```

RDS API

To configure an Aurora Serverless v1 DB cluster when you restore from a DB cluster using the RDS API, run the RestoreDBClusterFromSnapshot operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Modifying an Aurora Serverless v1 DB cluster

After you configure an Aurora Serverless v1 DB cluster, you can modify certain properties with the AWS Management Console, the AWS CLI, or the RDS API. Most of the properties you can modify are the same as for other kinds of Aurora clusters.

The most relevant changes for Aurora Serverless v1 are the following:

- Modifying the scaling configuration
- Upgrading the major version
- Converting from Aurora Serverless v1 to provisioned

Modifying the scaling configuration of an Aurora Serverless v1 DB cluster

You can set the minimum and maximum capacity for the DB cluster. Each capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory. You can also set whether Aurora Serverless pauses the database when there's no activity and then resumes when activity begins again.

You can set the following specific values for the scaling configuration:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Autoscaling timeout and action** – This section specifies how long Aurora Serverless waits to find a scaling point before timing out. It also specifies the action to take when a capacity modification times out because it can't find a scaling point. Aurora can force the capacity change to set the capacity to the specified value as soon as possible. Or, it can roll back the capacity change to cancel it. For more information, see Timeout action for capacity changes.
- **Pause after inactivity** – Use the optional **Scale the capacity to 0 ACUs when cluster is idle** setting to scale the database to zero processing capacity while it's inactive. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

Console

You can modify the scaling configuration of an Aurora DB cluster with the AWS Management Console.

To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Modify cluster**.
5. In the **Capacity settings** section, modify the scaling configuration.
6. Choose **Continue**.
7. On the **Modify DB cluster** page, review your modifications, then choose when to apply them.
8. Choose **Modify cluster**.

AWS CLI

To modify the scaling configuration of an Aurora Serverless v1 DB cluster using the AWS CLI, run the modify-db-cluster AWS CLI command. Specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you modify the scaling configuration of an Aurora Serverless v1 DB cluster named *`sample-cluster`*.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --scaling-configuration
 MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --scaling-configuration
 MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange
```

RDS API

You can modify the scaling configuration of an Aurora DB cluster with the ModifyDBCluster API operation. Specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Upgrading the major version of an Aurora Serverless v1 DB cluster

You can upgrade the major version for an Aurora Serverless v1 DB cluster compatible with PostgreSQL 11 to a corresponding PostgreSQL 13–compatible version.

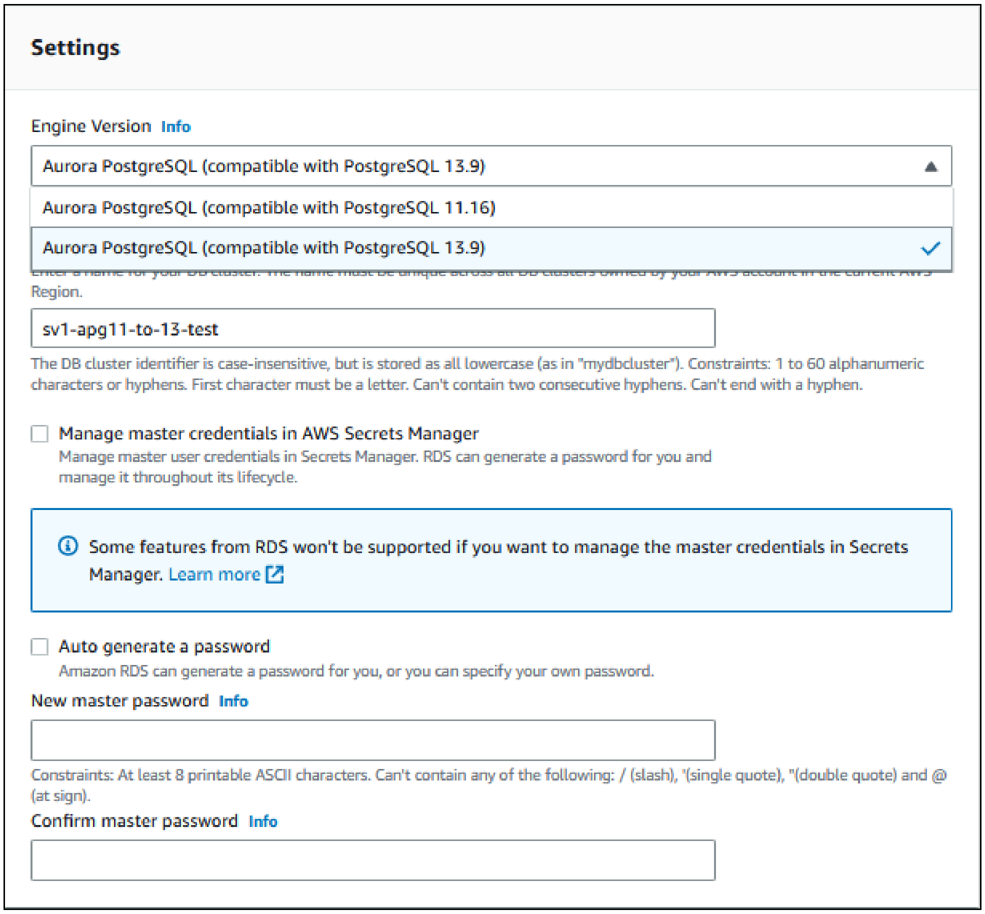
Console

You can perform an in-place upgrade of an Aurora Serverless v1 DB cluster using the AWS Management Console.

To upgrade an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to upgrade.
4. For **Actions**, choose **Modify cluster**.
5. For **Version**, choose an Aurora PostgreSQL version 13 version number.

   The following example shows an in-place upgrade from Aurora PostgreSQL 11.16 to 13.9.



Settings

Engine Version Info

Aurora PostgreSQL (compatible with PostgreSQL 13.9) ▲

Aurora PostgreSQL (compatible with PostgreSQL 11.16)

Aurora PostgreSQL (compatible with PostgreSQL 13.9) ✓

Region.

sv1-apg11-to-13-test

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

□ Manage master credentials in AWS Secrets Manager
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

ⓘ Some features from RDS won't be supported if you want to manage the master credentials in Secrets Manager. Learn more

□ Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password.

New master password Info

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm master password Info

If you perform a major version upgrade, leave all of the other properties the same. To change any other properties, do another **Modify** operation after the upgrade finishes.

6. Choose **Continue**.
7. On the **Modify DB cluster** page, review your modifications, then choose when to apply them.
8. Choose **Modify cluster**.

AWS CLI

To perform an in-place upgrade from a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster to a PostgreSQL 13–compatible one, specify the `--engine-version` parameter with an Aurora PostgreSQL version 13 version number that's compatible with Aurora Serverless v1. Also include the `--allow-major-version-upgrade` parameter.

In this example, you modify the major version of a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster named `sample-cluster`. Doing so performs an in-place upgrade to a PostgreSQL 13–compatible Aurora Serverless v1 DB cluster.

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --engine-version 13.9 \
    --allow-major-version-upgrade
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --engine-version 13.9 ^
    --allow-major-version-upgrade
```

RDS API

To perform an in-place upgrade from a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster to a PostgreSQL 13–compatible one, specify the `EngineVersion` parameter with an Aurora PostgreSQL version 13 version number that's compatible with Aurora Serverless v1. Also include the `AllowMajorVersionUpgrade` parameter.

Converting an Aurora Serverless v1 DB cluster to provisioned

You can convert an Aurora Serverless v1 DB cluster to a provisioned DB cluster. To perform the conversion, you change the DB instance class to **Provisioned**. You can use this conversion as part of upgrading your DB cluster from Aurora Serverless v1 to Aurora Serverless v2. For more information, see Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2.

The conversion process creates a reader DB instance in the DB cluster, promotes the reader instance to a writer instance, and then deletes the original Aurora Serverless v1 instance. When you convert the DB cluster, you can't perform any other modifications at the same time, such as changing the DB engine version or DB cluster parameter group. The conversion operation is applied immediately, and can't be undone.

During the conversion, a backup DB cluster snapshot is taken of the DB cluster in case an error occurs. The identifier for the DB cluster snapshot has the form pre-modify-engine-mode-*DB_cluster_identifier*-*timestamp*.

Aurora uses the current default DB minor engine version for the provisioned DB cluster.

If you don't provide a DB instance class for your converted DB cluster, Aurora recommends one based on the maximum capacity of the original Aurora Serverless v1 DB cluster. The recommended capacity to instance class mappings are shown in the following table.

Serverless maximum capacity (ACUs)	Provisioned DB instance class
1	db.t3.small
2	db.t3.medium
4	db.t3.large
8	db.r5.large
16	db.r5.xlarge
32	db.r5.2xlarge
64	db.r5.4xlarge
128	db.r5.8xlarge
192	db.r5.12xlarge
256	db.r5.16xlarge
384	db.r5.24xlarge

Note

Depending on the DB instance class you choose, and your database usage, you might see different costs for a provisioned DB cluster compared to Aurora Serverless v1.

If you convert your Aurora Serverless v1 DB cluster to a burstable (db.t*) DB instance class, you might incur additional costs for using the DB cluster. For more information, see DB instance class types.

AWS CLI

To convert an Aurora Serverless v1 DB cluster to a provisioned cluster, run the modify-db-cluster AWS CLI command.

The following parameters are required:

- `--db-cluster-identifier` – The Aurora Serverless v1 DB cluster that you're converting to provisioned.
- `--engine-mode` – Use the value `provisioned`.
- `--allow-engine-mode-change`
- `--db-cluster-instance-class` – Choose the DB instance class for the provisioned DB cluster based on the capacity of the Aurora Serverless v1 DB cluster.

In this example, you convert an Aurora Serverless v1 DB cluster named `sample-cluster` and use the `db.r5.xlarge` DB instance class.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --engine-mode provisioned \
    --allow-engine-mode-change \
    --db-cluster-instance-class db.r5.xlarge
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --engine-mode provisioned ^
    --allow-engine-mode-change ^
    --db-cluster-instance-class db.r5.xlarge
```

RDS API

To convert an Aurora Serverless v1 DB cluster to a provisioned cluster, use the ModifyDBCluster API operation.

The following parameters are required:

- `DBClusterIdentifier` – The Aurora Serverless v1 DB cluster that you're converting to provisioned.
- `EngineMode` – Use the value `provisioned`.
- `AllowEngineModeChange`
- `DBClusterInstanceClass` – Choose the DB instance class for the provisioned DB cluster based on the capacity of the Aurora Serverless v1 DB cluster.

Scaling Aurora Serverless v1 DB cluster capacity manually

Typically, Aurora Serverless v1 DB clusters scale seamlessly based on the workload. However, capacity might not always scale fast enough to meet sudden extremes, such as an exponential increase in transactions. In such cases you can initiate the scaling operation manually by setting a new capacity value. After you set the capacity explicitly, Aurora Serverless v1 automatically scales the DB cluster. It does so based on the cooldown period for scaling down.

You can explicitly set the capacity of an Aurora Serverless v1 DB cluster to a specific value with the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can set the capacity of an Aurora DB cluster with the AWS Management Console.

To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Set capacity**.
5. In the **Scale database capacity** window, choose the following:

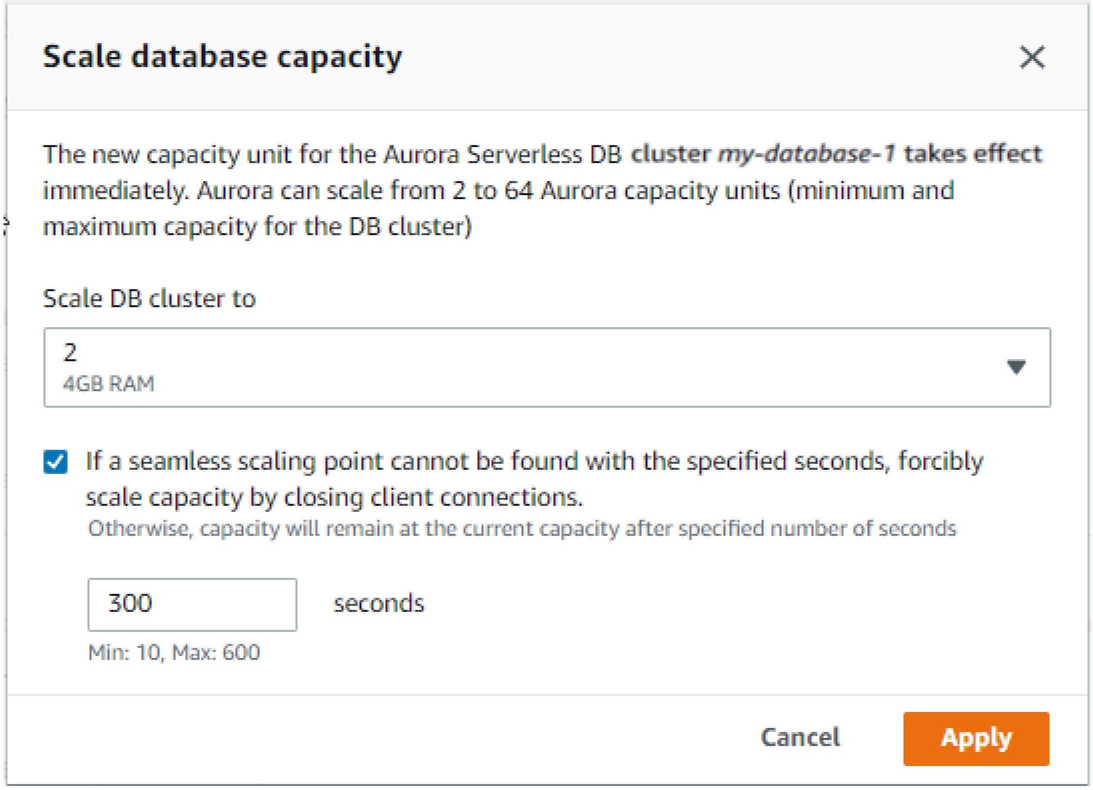
    a. For the **Scale DB cluster to** drop-down selector, choose the new capacity that you want for your DB cluster.

    b. For the **If a seamless scaling point cannot be found** check box, choose the behavior that you want for your Aurora Serverless v1 DB cluster's `TimeoutAction` setting, as follows:

    - Clear this option if you want your capacity to remain unchanged if Aurora Serverless v1 can't find a scaling point before timing out.

  - Select this option if you want to force your Aurora Serverless v1 DB cluster change its capacity even if it can't find a scaling point before timing out. This option can result Aurora Serverless v1 dropping connections that prevent it from finding a scaling point.

c. For **seconds**, enter the amount of time you want to allow your Aurora Serverless v1 DB cluster to look for a scaling point before timing out. You can specify anywhere from 10 seconds to 600 seconds (10 minutes). The default is five minutes (300 seconds). This following example forces the Aurora Serverless v1 DB cluster to scale down to 2 ACUs even if it can't find a scaling point within five minutes.



Scale database capacity

The new capacity unit for the Aurora Serverless DB cluster *my-database-1* takes effect immediately. Aurora can scale from 2 to 64 Aurora capacity units (minimum and maximum capacity for the DB cluster)

Scale DB cluster to

2
4GB RAM

☑ If a seamless scaling point cannot be found with the specified seconds, forcibly scale capacity by closing client connections.
Otherwise, capacity will remain at the current capacity after specified number of seconds

300 seconds
Min: 10, Max: 600

6. Choose **Apply**.

To learn more about scaling points, `TimeoutAction`, and cooldown periods, see Autoscaling for Aurora Serverless v1.

AWS CLI

To set the capacity of an Aurora Serverless v1 DB cluster using the AWS CLI, run the modify-current-db-cluster-capacity AWS CLI command, and specify the `--capacity` option. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.

- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you set the capacity of an Aurora Serverless v1 DB cluster named *sample-cluster* to *64*.

```
aws rds modify-current-db-cluster-capacity --db-cluster-identifier sample-cluster --
capacity 64
```

RDS API

You can set the capacity of an Aurora DB cluster with the ModifyCurrentDBClusterCapacity API operation. Specify the `Capacity` parameter. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Viewing Aurora Serverless v1 DB clusters

After you create one or more Aurora Serverless v1 DB clusters, you can view which DB clusters are type **Serverless** and which are type **Instance**. You can also view the current number of Aurora capacity units (ACUs) each Aurora Serverless v1 DB cluster is using. Each ACU is a combination of processing (CPU) and memory (RAM) capacity.

To view your Aurora Serverless v1 DB clusters

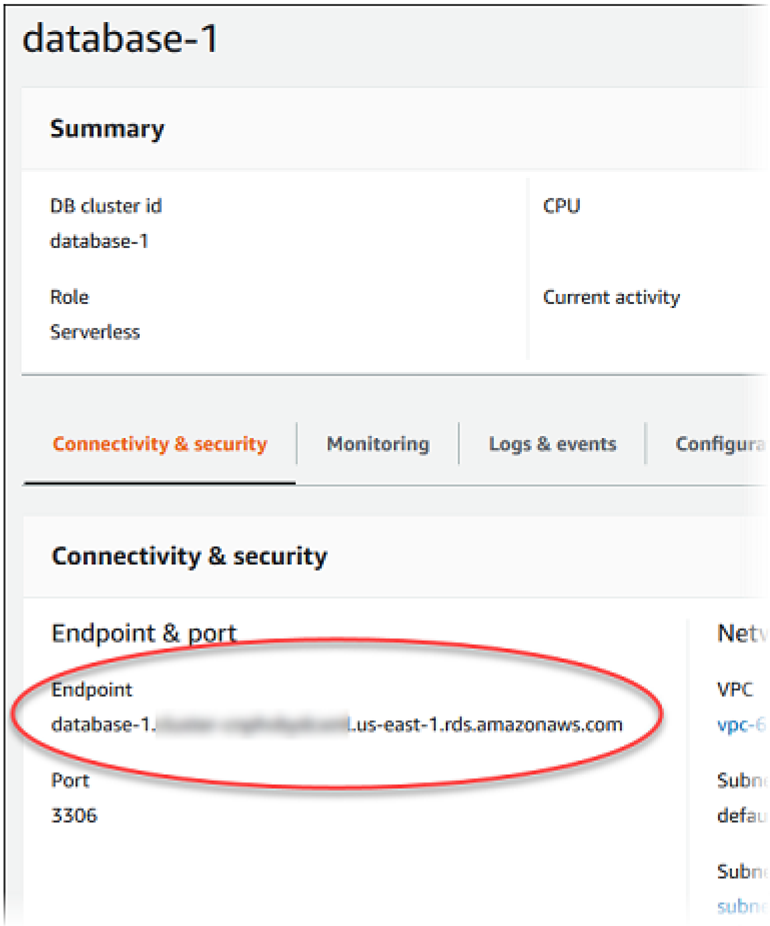
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters.
3. In the navigation pane, choose **Databases**.

   For each DB cluster, the DB cluster type is shown under **Role**. The Aurora Serverless v1 DB clusters show **Serverless** for the type. You can view an Aurora Serverless v1 DB cluster's current capacity under **Size**.

	DB identifier ▲	Role ▼	Engine ▼	Region & AZ ▼	Size ▼	Sta
○	database-1	Serverless	Aurora MySQL	us-east-1	0 capacity units	✓
○	my-database-1	Serverless	Aurora PostgreSQL	us-east-1	0 capacity units	✓
○	mysqls3	Instance	MySQL	us-east-1c	db.t3.medium	✓
○	⊟ tests3aurora	Regional	Aurora MySQL	us-east-1	2 instances	✓
○	tests3aurora	Writer	Aurora MySQL	us-east-1a	db.t3.medium	✓
○	tests3aurora-us-east-1b	Reader	Aurora MySQL	us-east-1b	db.t3.medium	✓

4. Choose the name of an Aurora Serverless v1 DB cluster to display its details.

   On the **Connectivity & security** tab, note the database endpoint. Use this endpoint to connect to your Aurora Serverless v1 DB cluster.



database-1

Time	System notes
Mon Aug 06 17:04:15 GMT-700 2018	The DB cluster has scaled from 8 capacity units to 4 capacity units.
Mon Aug 06 17:04:09 GMT-700 2018	Scaling DB cluster from 8 capacity units to 4 capacity units for this

Monitoring capacity and scaling events for your Aurora Serverless v1 DB cluster

You can view your Aurora Serverless v1 DB cluster in CloudWatch to monitor the capacity allocated to the DB cluster with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `CPUUtilization`, `DatabaseConnections`, `Queries`, and so on.

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by enabling the configuration parameters such as `general_log` and `slow_query_log` in the DB cluster parameter group associated with theAurora Serverless v1 cluster. Unlike provisioned clusters, Aurora Serverless v1 clusters don't require you to specify in the DB cluster settings which log types to upload to CloudWatch. Aurora Serverless v1 clusters automatically upload all the available logs. When you disable a log configuration parameter, publishing of the log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

To get started with Amazon CloudWatch for your Aurora Serverless v1 DB cluster, see Viewing Aurora Serverless v1 logs with Amazon CloudWatch. To learn more about how to monitor Aurora DB clusters through CloudWatch, see Monitoring log events in Amazon CloudWatch.

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For more information, see Connecting to an Amazon Aurora DB cluster.

Note

You can't connect directly to specific DB instances in your Aurora Serverless v1 DB clusters.

Deleting an Aurora Serverless v1 DB cluster

When you create an Aurora Serverless v1 DB cluster using the AWS Management Console, the **Enable default protection** option is enabled by default unless you deselect it. That means that you can't immediately delete an Aurora Serverless v1 DB cluster that has **Deletion protection** enabled. To delete Aurora Serverless v1 DB clusters that have deletion protection by using the AWS Management Console, you first modify the cluster to remove this protection. For information about using the AWS CLI for this task, see AWS CLI.

To disable deletion protection using the AWS Management Console

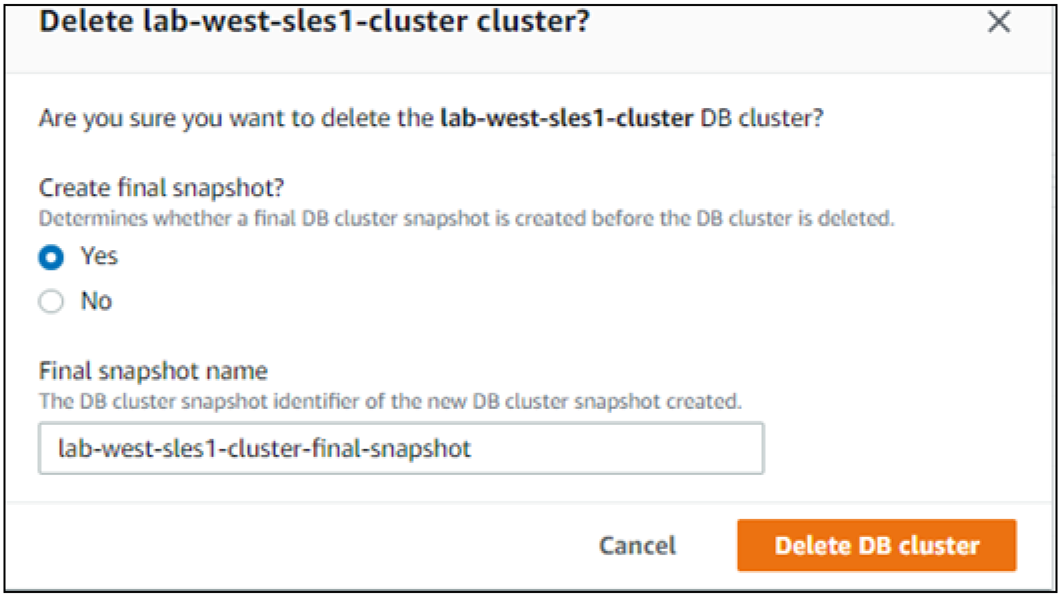
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **DB clusters**.
3. Choose your Aurora Serverless v1 DB cluster from the list.
4. Choose **Modify** to open your DB cluster's configuration. The Modify DB cluster page opens the Settings, Capacity settings, and other configuration details for your Aurora Serverless v1 DB cluster. Deletion protection is in the **Additional configuration** section.
5. Clear the **Enable deletion protection** check box in the **Additional configuration** properties card.
6. Choose **Continue**. The **Summary of modifications** appears.
7. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

After deletion protection is no longer active, you can delete your Aurora Serverless v1 DB cluster by using the AWS Management Console.

Console

To delete an Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the **Resources** section, choose **DB Clusters**.
3. Choose the Aurora Serverless v1 DB cluster that you want to delete.
4. For **Actions**, choose **Delete**. You're prompted to confirm that you want to delete your Aurora Serverless v1 DB cluster.
5. We recommend that you keep the preselected options:
   - **Yes** for **Create final snapshot?**
   - Your Aurora Serverless v1 DB cluster name plus `-final-snapshot` for **Final snapshot name**. However, you can change the name for your final snapshot in this field.



Delete lab-west-sles1-cluster cluster?

Are you sure you want to delete the **lab-west-sles1-cluster** DB cluster?

Create final snapshot?
Determines whether a final DB cluster snapshot is created before the DB cluster is deleted.

● Yes

○ No

Final snapshot name
The DB cluster snapshot identifier of the new DB cluster snapshot created.

lab-west-sles1-cluster-final-snapshot

If you choose **No** for **Create final snapshot?** you can't restore your DB cluster using snapshots or point-in-time recovery.

6. Choose **Delete DB cluster**.

Aurora Serverless v1 deletes your DB cluster. If you chose to have a final snapshot, you see your Aurora Serverless v1 DB cluster's status change to "Backing-up" before it's deleted and no longer appears in the list.

AWS CLI

Before you begin, configure your AWS CLI with your AWS Access Key ID, AWS Secret Access Key, and the AWS Region where your Aurora Serverless v1 DB cluster is. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

You can't delete an Aurora Serverless v1 DB cluster until after you first disable deletion protection for clusters configured with this option. If you try to delete a cluster that has this protection option enabled, you see the following error message.

```
An error occurred (InvalidParameterCombination) when calling the DeleteDBCluster
  operation: Cannot delete protected Cluster, please disable deletion protection and
 try again.
```

You can change your Aurora Serverless v1 DB cluster's deletion-protection setting by using the modify-db-cluster AWS CLI command as shown in the following:

```
aws rds modify-db-cluster --db-cluster-identifier your-cluster-name --no-deletion-
protection
```

This command returns the revised properties for the specified DB cluster. You can now delete your Aurora Serverless v1 DB cluster.

We recommend that you always create a final snapshot whenever you delete an Aurora Serverless v1 DB cluster. The following example of using the AWS CLI delete-db-cluster shows you how. You provide the name of your DB cluster and a name for the snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster --db-cluster-identifier \
  your-cluster-name --no-skip-final-snapshot \
  --final-db-snapshot-identifier name-your-snapshot
```

For Windows:

```
aws rds delete-db-cluster --db-cluster-identifier ^
  your-cluster-name --no-skip-final-snapshot ^
  --final-db-snapshot-identifier name-your-snapshot
```

Aurora Serverless v1 and Aurora database engine versions

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For the current list of AWS Regions that support Aurora Serverless v1 and the specific Aurora MySQL and Aurora PostgreSQL versions available in each Region, see Supported Regions and Aurora DB engines for Aurora Serverless v1.

Aurora Serverless v1 uses its associated Aurora database engine to identify specific supported releases for each database engine supported, as follows:

- Aurora MySQL Serverless
- Aurora PostgreSQL Serverless

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various AWS Regions where Aurora Serverless v1 is available. In other words, you don't need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster's DB engine when it's available for Aurora Serverless v1.

Aurora MySQL Serverless

If you want to use Aurora MySQL-Compatible Edition for your Aurora Serverless v1 DB cluster, you can choose an Aurora MySQL version 2 that's compatible with MySQL 5.7. To learn about enhancements and bug fixes for Aurora MySQL version 2, see Database engine updates for Amazon Aurora MySQL version 2 in the *Release Notes for Aurora MySQL*.

Aurora PostgreSQL Serverless

If you want to use Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can choose among Aurora PostgreSQL 11-compatible and 13-compatible versions. Minor releases for Aurora PostgreSQL-Compatible Edition include only changes that are backward-compatible. Your Aurora Serverless v1 DB cluster is transparently upgraded when an Aurora PostgreSQL minor release becomes available for Aurora Serverless v1 in your AWS Region.

For example, the minor version Aurora PostgreSQL 11.16 release was transparently applied to all Aurora Serverless v1 DB clusters running the previous Aurora PostgreSQL version. For more information about the Aurora PostgreSQL version 11.16 update, see PostgreSQL 11.16 in the *Release Notes for Aurora PostgreSQL*.

Using RDS Data API

By using RDS Data API (Data API), you can work with a web-services interface to your Aurora DB cluster. Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with AWS SDKs. You can use the endpoint to run SQL statements without managing connections.

Users don't need to pass credentials with calls to Data API, because Data API uses database credentials stored in AWS Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also Data API. For more information about authorizing users, see Authorizing access to RDS Data API.

You can also use Data API to integrate Amazon Aurora with other AWS applications such as AWS Lambda, AWS AppSync, and AWS Cloud9. Data API provides a more secure way to use AWS Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see AWS Lambda, AWS AppSync, and AWS Cloud9.

You can enable Data API when you create the Aurora DB cluster. You can also modify the configuration later. For more information, see Enabling RDS Data API.

After you enable Data API, you can also use the query editor to run ad hoc queries without configuring a query tool to access Aurora in a VPC. For more information, see Using the Aurora query editor.

Topics

- Logging RDS Data API calls with AWS CloudTrail

Region and version availability

For information about the Regions and engine versions available for Data API, see the following sections.

Cluster type	Region and version availability
Aurora PostgreSQL provisioned and Serverless v2	Data API with Aurora PostgreSQL Serverless v2 and provisioned
Aurora PostgreSQL Serverless v1	Data API with Aurora PostgreSQL Serverless v1
Aurora MySQL Serverless v1	Data API with Aurora MySQL Serverless v1

> **Note**
>
> Currently, Data API isn't available for provisioned or Aurora Serverless v2 DB clusters that use the MySQL engine.

If you require cryptographic modules validated by FIPS 140-2 when accessing Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Limitations with RDS Data API

RDS Data API (Data API) has the following limitations:

- You can only execute Data API queries on writer instances in a DB cluster. However, writer instances can accept both write and read queries.
- With Aurora global databases, you can enable Data API on both primary and secondary DB clusters. However, until a secondary cluster is promoted to be the primary, it has no writer

instance. Thus, Data API queries that you send to the secondary fail. After a promoted secondary has an available writer instance, Data API queries on that DB instance should succeed.

- Performance Insights doesn't support monitoring database queries that you make using Data API.
- Data API isn't supported on T DB instance classes.
- For Aurora Serverless v2 and provisioned DB clusters that use the PostgreSQL engine, RDS Data API doesn't support some data types. For the list of supported types, see the section called “Comparison with Serverless v2 and provisioned, and Aurora Serverless v1”.
- For Aurora PostgreSQL version 14 and higher databases, Data API only supports scram-sha-256 for password encryption.

Comparison of RDS Data API with Serverless v2 and provisioned, and Aurora Serverless v1

The following table describes differences between RDS Data API (Data API) with Aurora PostgreSQL Serverless v2 and provisioned DB clusters, and Aurora Serverless v1 DB clusters. Aurora Serverless v1 DB clusters use the `serverless` engine mode. Provisioned DB clusters use the `provisioned` engine mode. An Aurora Serverless v2 DB cluster also uses the `provisioned` engine mode, and contains one or more Aurora Serverless v2 DB instances with the `db.serverless` instance class.

Difference	Aurora PostgreSQL Serverless v2 and provisioned	Aurora Serverless v1
Maximum number of requests per second	Unlimited	1,000
Enabling or disabling Data API on an existing database by using the RDS API or AWS CLI	• RDS API – Use the `EnableHttpEndpoint` and `DisableHttpEndpoint` operations. • AWS CLI – Use the `enable-http-endpoint` and `disable-http-endpoint` operations.	• RDS API – Use the `ModifyDBCluster` operation, and specify `true` or `false`, as applicable, for the `EnableHttpEndpoint` parameter. • AWS CLI – Use the `modify-db-cluster` operation

Difference	Aurora PostgreSQL Serverless v2 and provisioned	Aurora Serverless v1
		with the `--enable-http-endpoint` or `--no-enable-http-endpoint` option, as applicable.
CloudTrail events	Events from Data API calls are data events. These events are automatically excluded in a trail by default. For more information, see the section called "Including Data API events in an CloudTrail trail".	Events from Data API calls are management events. These events are automatically included in a trail by default. For more information, see the section called "Excluding Data API events from a CloudTrail trail (Aurora Serverless v1 only)".
Multistatement support	Multistatements aren't supported. In this case, Data API throws `ValidationException: Multistatements aren't supported.`	For Aurora PostgreSQL, multistatements return only the first query response. For Aurora MySQL, multistatements aren't supported.
BatchExecuteStatement	The generated fields object in the update result is empty.	The generated fields object in the update result includes inserted values.
ExecuteSQL	Not supported	Deprecated

Difference	Aurora PostgreSQL Serverless v2 and provisioned	Aurora Serverless v1
ExecuteStatement	ExecuteStatement doesn't support retrieving multidimentional array columns. In this case, Data API throws UnsupportedResultException . Data API doesn't support some data types, such as geometric and monetary types. In this case, Data API throws UnsupportedResultException: The result contains the unsupported data type *data_type* . Only the following types are supported: - BOOL - BYTEA - DATE - CIDR - DECIMAL, NUMERIC - ENUM - FLOAT8, DOUBLE PRECISION - INET - INT, INT4, SERIAL - INT2, SMALLINT, SMALLSERIAL	ExecuteStatement supports retrieving multidimentional array columns and all advanced data types.

Difference	Aurora PostgreSQL Serverless v2 and provisioned	Aurora Serverless v1
	• INT8, BIGINT, BIGSERIAL • JSONB, JSON • REAL, FLOAT • TEXT, CHAR(N), VARCHAR, NAME • TIME • TIMESTAMP • UUID • VECTOR Only the following array types are supported: • BOOL[], BIT[] • DATE[] • DECIMAL[] , NUMERIC[] • FLOAT8[], DOUBLE PRECISION[] • INT[], INT4[] • INT2[] • INT8[], BIGINT[] • JSON[] • REAL[], FLOAT[] • TEXT[], CHAR(N)[] , VARCHAR[] , NAME[] • TIME[] • TIMESTAMP[] • UUID[]	

Authorizing access to RDS Data API

Users can invoke RDS Data API (Data API) operations only if they are authorized to do so. You can give a user permission to use Data API by attaching an AWS Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An AWS managed policy, `AmazonRDSDataFullAccess`, includes permissions for Data API.

The `AmazonRDSDataFullAccess` policy also includes permissions for the user to get the value of a secret from AWS Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to Data API. Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with Data API, see Storing database credentials in AWS Secrets Manager.

The `AmazonRDSDataFullAccess` policy provides complete access (through Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*"
        },
        {
            "Sid": "RDSDataServiceAccess",
            "Effect": "Allow",
            "Action": [
                "rds-data:BatchExecuteStatement",
                "rds-data:BeginTransaction",
                "rds-data:CommitTransaction",
                "rds-data:ExecuteStatement",
                "rds-data:RollbackTransaction"
            ],
            "Resource": "arn:aws:rds:us-east-2:111122223333:cluster:prod"
        }
    ]
}
```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (*).

Working with tag-based authorization

RDS Data API (Data API) and Secrets Manager both support tag-based authorization. *Tags* are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:

- `environment:production`
- `environment:development`

You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. (If you don't already have tags on your resources and you want to apply them, you can learn more at Tagging Amazon RDS resources.) You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an `environment:production` tag.

Here's how the policy is applied: When a user makes a call using Data API, the request is sent to the service. Data API first verifies that the cluster ARN passed in the request is tagged with `environment:production`. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with `environment:production`. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                 "secretsmanager:GetSecretValue"
               ],
            "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*",
            "Condition": {
                    "StringEquals": {
                        "aws:ResourceTag/environment": [
                                         "production"
                                        ]
                     }
             }
        },
        {
            "Sid": "RDSDataServiceAccess",
            "Effect": "Allow",
            "Action": [
                  "rds-data:*"
               ],
            "Resource": "arn:aws:rds:us-east-2:111122223333:cluster:*",
            "Condition": {
                    "StringEquals": {
                        "aws:ResourceTag/environment": [
                                         "production"
                                        ]
                     }
             }
         }
     ]
}
```

The example shows separate actions for `rds-data` and `secretsmanager` for Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see Using identity-based policies (IAM policies) for Secrets Manager.

In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see Controlling access to AWS resources using resource tags.

> **Note**
>
> Both Data API and AWS Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

Storing database credentials in AWS Secrets Manager

When you call RDS Data API (Data API), you pass credentials for the Aurora DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.

   For instructions, see Create a database secret in the *AWS Secrets Manager User Guide*.
2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` AWS CLI command.

   Note the name and ARN of the secret. You can use them in calls to Data API.

For more information about using Secrets Manager, see the AWS Secrets Manager User Guide.

To understand how Amazon Aurora manages identity and access management, see How Amazon Aurora works with IAM.

For more information about creating an IAM policy, see Creating IAM Policies in the *IAM User Guide*. For information about adding an IAM policy to a user, see Adding and Removing IAM Identity Permissions in the *IAM User Guide*.

Enabling RDS Data API

To use RDS Data API (Data API), enable it for your Aurora DB cluster. You can enable Data API when you create or modify the DB cluster.

Note

For Aurora PostgreSQL, Data API is supported with Aurora Serverless v2, Aurora Serverless v1, and provisioned databases. For Aurora MySQL, Data API is only supported with Aurora Serverless v1 databases.

Topics

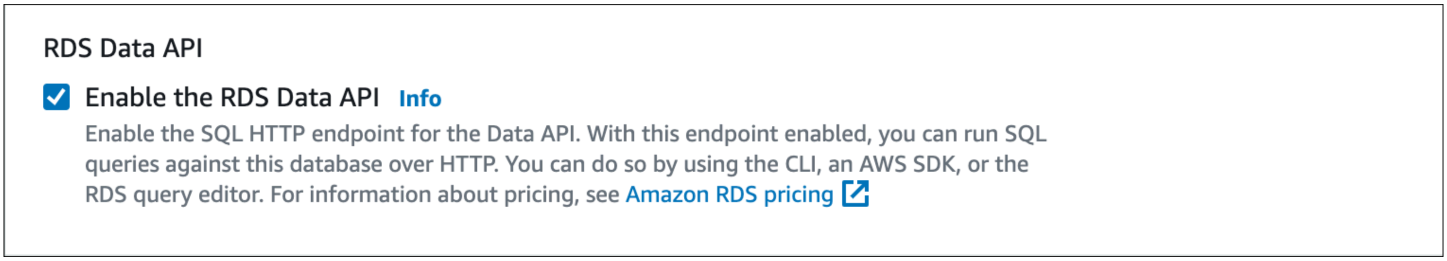
- Enabling RDS Data API when you create a database
- Enabling RDS Data API on an existing database

Enabling RDS Data API when you create a database

While you are creating a database that supports RDS Data API (Data API), you can enable this feature. The following procedures describe how to do so when you use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To enable Data API when you create a DB cluster, select the **Enable the RDS Data API** checkbox in the **Connectivity** section of the **Create database** page, as in the following screenshot.



RDS Data API

☑ Enable the RDS Data API Info

Enable the SQL HTTP endpoint for the Data API. With this endpoint enabled, you can run SQL queries against this database over HTTP. You can do so by using the CLI, an AWS SDK, or the RDS query editor. For information about pricing, see Amazon RDS pricing

For instructions on how to create an Aurora DB cluster that can use the RDS Data API, see the following:

- For Aurora PostgreSQL Serverless v2 and provisioned clusters – Creating an Amazon Aurora DB cluster
- For Aurora Serverless v1 – Creating an Aurora Serverless v1 DB cluster

AWS CLI

To enable Data API while you're creating an Aurora DB cluster, run the create-db-cluster AWS CLI command with the `--enable-http-endpoint` option.

The following example creates an Aurora PostgreSQL DB cluster with Data API enabled.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
    --db-cluster-identifier my_pg_cluster \
    --engine aurora-postgresql \
    --enable-http-endpoint
```

For Windows:

```
aws rds create-db-cluster ^
    --db-cluster-identifier my_pg_cluster ^
    --engine aurora-postgresql ^
    --enable-http-endpoint
```

RDS API

To enable Data API while you're creating an Aurora DB cluster, use the CreateDBCluster operation with the value of the `EnableHttpEndpoint` parameter set to `true`.

Enabling RDS Data API on an existing database

You can modify a DB cluster that supports RDS Data API (Data API) to enable or disable this feature.

Topics

- Enabling or disabling Data API (Aurora PostgreSQL Serverless v2 and provisioned)
- Enabling or disabling Data API (Aurora Serverless v1 only)

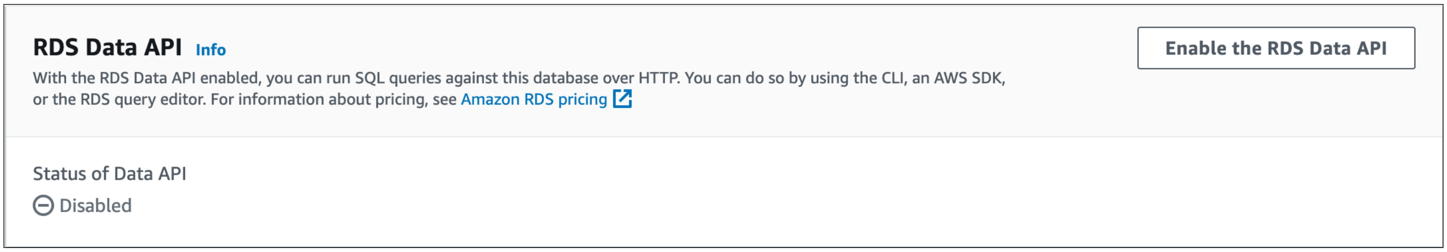
Enabling or disabling Data API (Aurora PostgreSQL Serverless v2 and provisioned)

Use the following procedures to enable or disable Data API on Aurora PostgreSQL Serverless v2 and provisioned databases. To enable or disable Data API on Aurora Serverless v1 databases, use the procedures in the section called "Enabling or disabling Data API (Aurora Serverless v1 only)".

Console

You can enable or disable Data API by using the RDS console for a DB cluster that supports this feature. To do so, open the cluster details page of the database on which you want to enable or disable Data API, and on the **Connectivity & security** tab, go to the **RDS Data API** section. This section displays the status of Data API, and allows you to enable or disable it.

The following screenshot shows that the **RDS Data API** isn't enabled.



With the RDS Data API enabled, you can run SQL queries against this database over HTTP. You can do so by using the CLI, an AWS SDK, or the RDS query editor. For information about pricing, see Amazon RDS pricing

Status of Data API

⊖ Disabled

AWS CLI

To enable or disable Data API on an existing database, run the enable-http-endpoint or disable-http-endpoint AWS CLI command, and specify the ARN of your DB cluster.

The following example enables Data API.

For Linux, macOS, or Unix:

```
aws rds enable-http-endpoint \
    --resource-arn cluster_arn
```

For Windows:

```
aws rds enable-http-endpoint ^
    --resource-arn cluster_arn
```

RDS API

To enable or disable Data API on an existing database, use the EnableHttpEndpoint and DisableHttpEndpoint operations.

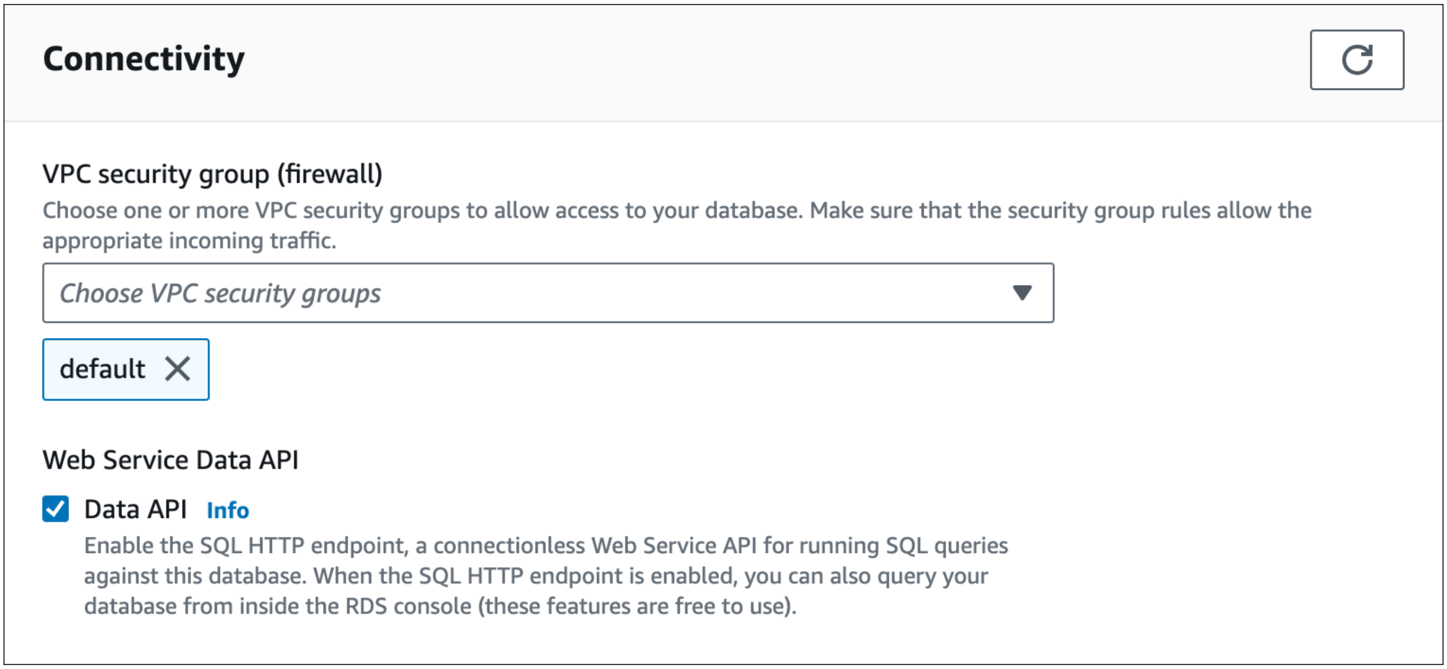
Enabling or disabling Data API (Aurora Serverless v1 only)

Use the following procedures to enable or disable Data API on existing Aurora Serverless v1 databases. To enable or disable Data API on Aurora PostgreSQL Serverless v2 and provisioned databases, use the procedures in the section called “Enabling or disabling Data API”.

Console

When you modify an Aurora Serverless v1 DB cluster, you enable Data API in the RDS console's **Connectivity** section.

The following screenshot shows the enabled **Data API** when modifying an Aurora DB cluster.



Connectivity

VPC security group (firewall)

Choose one or more VPC security groups to allow access to your database. Make sure that the security group rules allow the appropriate incoming traffic.

Choose VPC security groups ▼

default ✕

Web Service Data API

☑ Data API Info

Enable the SQL HTTP endpoint, a connectionless Web Service API for running SQL queries against this database. When the SQL HTTP endpoint is enabled, you can also query your database from inside the RDS console (these features are free to use).

For instructions on how to modify an Aurora Serverless v1 DB cluster, see [Modifying an Aurora Serverless v1 DB cluster](#).

AWS CLI

To enable or disable Data API, run the [modify-db-cluster](#) AWS CLI command, with the `--enable-http-endpoint` or `--no-enable-http-endpoint`, as applicable.

The following example enables Data API on `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --enable-http-endpoint
```

For Windows:

```
aws rds modify-db-cluster ^
```

```
    --db-cluster-identifier sample-cluster ^
    --enable-http-endpoint
```

RDS API

To enable Data API, use the ModifyDBCluster operation, and set the value of `EnableHttpEndpoint` to `true` or `false`, as applicable.

Creating an Amazon VPC endpoint for RDS Data API (AWS PrivateLink)

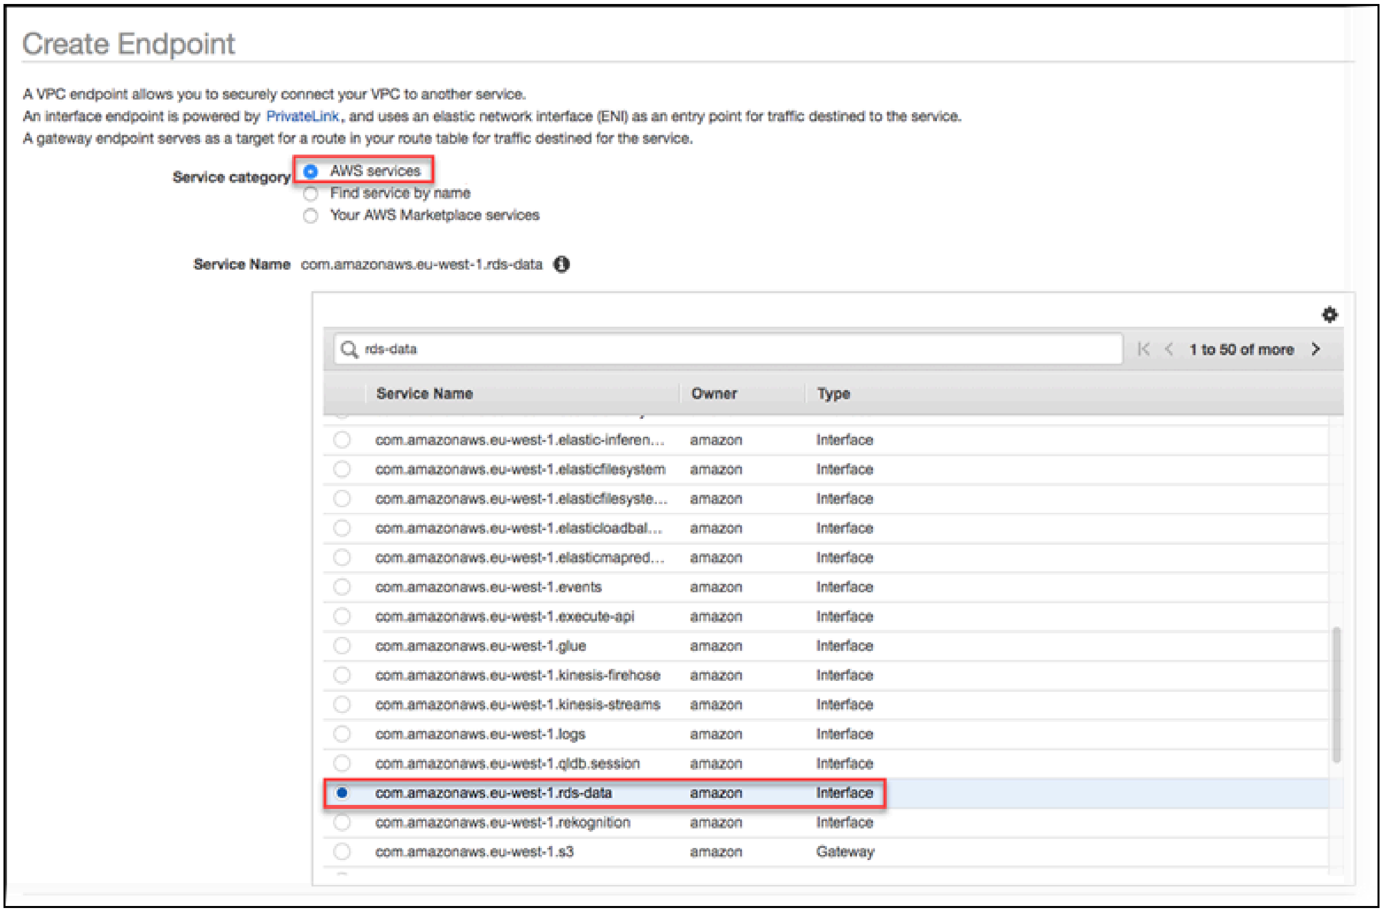
Amazon VPC enables you to launch AWS resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). AWS PrivateLink provides private connectivity between VPCs and AWS services with high security on the Amazon network. Using AWS PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about AWS PrivateLink, see VPC Endpoint Services (AWS PrivateLink) in the *Amazon Virtual Private Cloud User Guide*.

You can call RDS Data API (Data API) with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and Data API in the AWS network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

To create an Amazon VPC endpoint for Data API

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoints**, and then choose **Create Endpoint**.
3. On the **Create Endpoint** page, for **Service category**, choose **AWS services**. For **Service Name**, choose **rds-data**.



Create Endpoint

A VPC endpoint allows you to securely connect your VPC to another service.
An interface endpoint is powered by PrivateLink, and uses an elastic network interface (ENI) as an entry point for traffic destined to the service.
A gateway endpoint serves as a target for a route in your route table for traffic destined for the service.

Service category
● AWS services
○ Find service by name
○ Your AWS Marketplace services

Service Name com.amazonaws.eu-west-1.rds-data

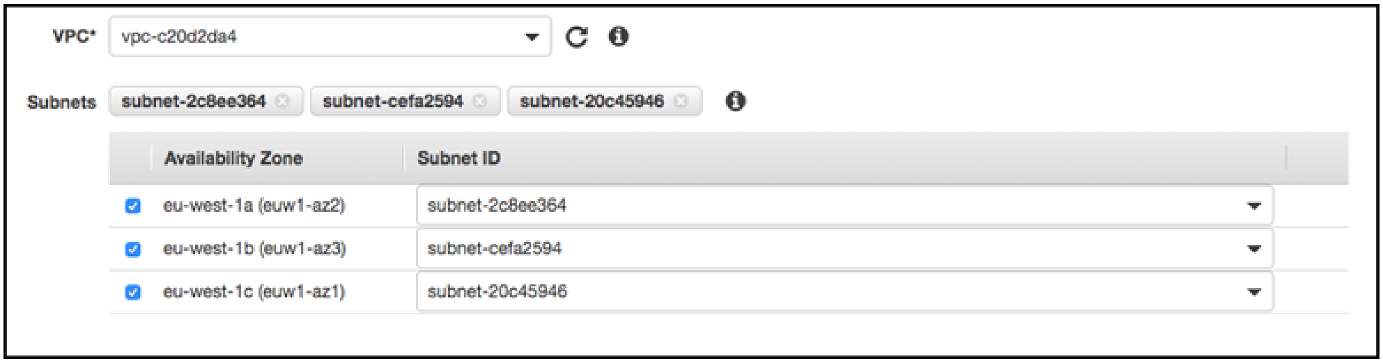
rds-data

	Service Name	Owner	Type
○	com.amazonaws.eu-west-1.elastic-inferen...	amazon	Interface
○	com.amazonaws.eu-west-1.elasticfilesystem	amazon	Interface
○	com.amazonaws.eu-west-1.elasticfilesyste...	amazon	Interface
○	com.amazonaws.eu-west-1.elasticloadbal...	amazon	Interface
○	com.amazonaws.eu-west-1.elasticmapred...	amazon	Interface
○	com.amazonaws.eu-west-1.events	amazon	Interface
○	com.amazonaws.eu-west-1.execute-api	amazon	Interface
○	com.amazonaws.eu-west-1.glue	amazon	Interface
○	com.amazonaws.eu-west-1.kinesis-firehose	amazon	Interface
○	com.amazonaws.eu-west-1.kinesis-streams	amazon	Interface
○	com.amazonaws.eu-west-1.logs	amazon	Interface
○	com.amazonaws.eu-west-1.qldb.session	amazon	Interface
●	com.amazonaws.eu-west-1.rds-data	amazon	Interface
○	com.amazonaws.eu-west-1.rekognition	amazon	Interface
○	com.amazonaws.eu-west-1.s3	amazon	Gateway

4. For **VPC**, choose the VPC to create the endpoint in.

   Choose the VPC that contains the application that makes Data API calls.

5. For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the AWS service that is running your application.



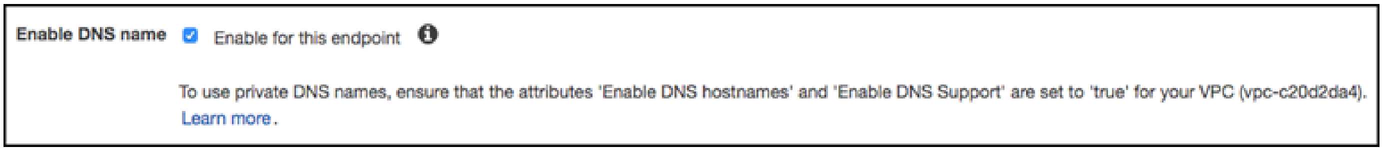
VPC* vpc-c20d2da4

Subnets subnet-2c8ee364 subnet-cefa2594 subnet-20c45946

	Availability Zone	Subnet ID
☑	eu-west-1a (euw1-az2)	subnet-2c8ee364
☑	eu-west-1b (euw1-az3)	subnet-cefa2594
☑	eu-west-1c (euw1-az1)	subnet-20c45946

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

6. For **Enable DNS name**, select **Enable for this endpoint**.



Enable DNS name ☑ Enable for this endpoint

To use private DNS names, ensure that the attributes 'Enable DNS hostnames' and 'Enable DNS Support' are set to 'true' for your VPC (vpc-c20d2da4). Learn more.

Private DNS resolves the standard Data API DNS hostname (`https://rds-data.`*`region`*`.amazonaws.com`) to the private IP addresses associated with the DNS hostname specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the AWS CLI or AWS SDKs without making any code or configuration changes to update Data API's endpoint URL.

7. For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

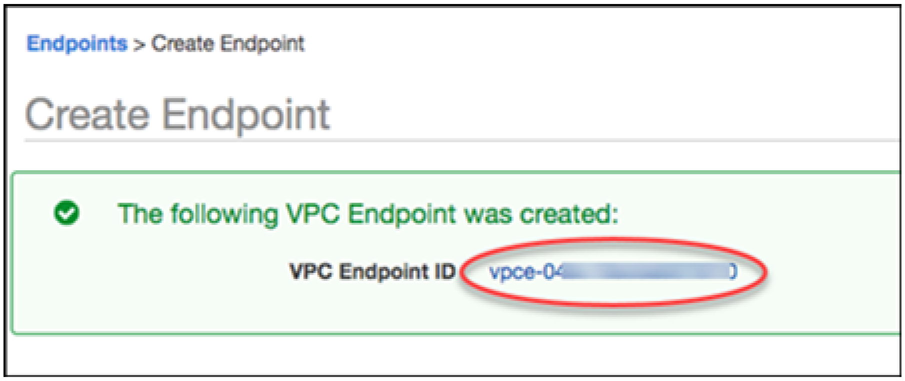
   Choose the security group that allows access to the AWS service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

8. For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

   If you choose **Custom**, enter the policy in the policy creation tool.

9. Choose **Create endpoint**.

After the endpoint is created, choose the link in the AWS Management Console to view the endpoint details.



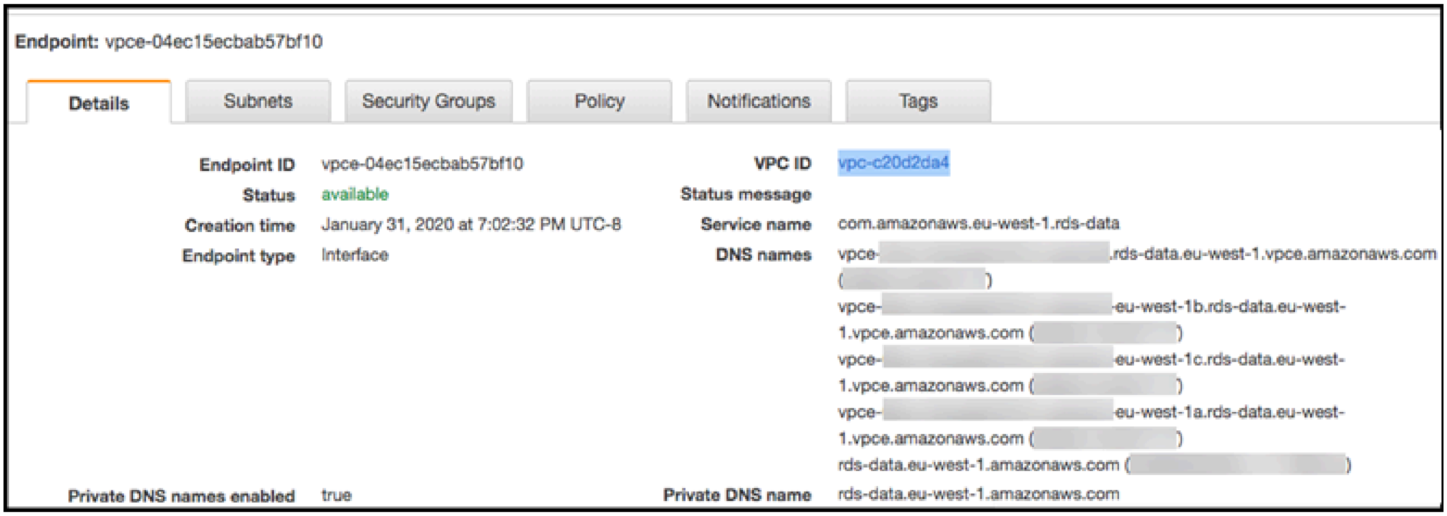
Endpoints > Create Endpoint

Create Endpoint

The following VPC Endpoint was created:

VPC Endpoint ID vpce-04[redacted]

The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.



Endpoint: vpce-04ec15ecbab57bf10

Endpoint ID vpce-04ec15ecbab57bf10

Status available

Creation time January 31, 2020 at 7:02:32 PM UTC-8

Endpoint type Interface

Private DNS names enabled true

VPC ID vpc-c20d2da4

Status message

Service name com.amazonaws.eu-west-1.rds-data

DNS names vpce-[redacted].rds-data.eu-west-1.vpce.amazonaws.com ([redacted])
vpce-[redacted]-eu-west-1b.rds-data.eu-west-1.vpce.amazonaws.com ([redacted])
vpce-[redacted]-eu-west-1c.rds-data.eu-west-1.vpce.amazonaws.com ([redacted])
vpce-[redacted]-eu-west-1a.rds-data.eu-west-1.vpce.amazonaws.com ([redacted])
rds-data.eu-west-1.amazonaws.com ([redacted])

Private DNS name rds-data.eu-west-1.amazonaws.com

You can use the standard endpoint (`rds-data.`*`region`*`.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling Data API, see Calling RDS Data API.

Calling RDS Data API

With RDS Data API (Data API) enabled on your Aurora DB cluster, you can run SQL statements on the Aurora DB cluster by using Data API or the AWS CLI. Data API supports the programming languages supported by the AWS SDKs. For more information, see Tools to build on AWS.

Topics

- Data API operations reference
- Calling RDS Data API with the AWS CLI
- Calling RDS Data API from a Python application
- Calling RDS Data API from a Java application
- Controlling Data API timeout behavior

Data API operations reference

Data API provides the following operations to perform SQL statements.

Data API operation	AWS CLI command	Description
ExecuteStatement	aws rds-data execute-statement	Runs a SQL statement on a database.
BatchExecuteStatement	aws rds-data batch-execute-statement	Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.

You can use either operation to run individual SQL statements or to run transactions. For transactions, Data API provides the following operations.

Data API operation	AWS CLI command	Description
BeginTransaction	aws rds-data begin-transaction	Starts a SQL transaction.
CommitTransaction	aws rds-data commit-transaction	Ends a SQL transaction and commits the changes.
RollbackTransaction	aws rds-data rollback-transaction	Performs a rollback of a transaction.

The operations for performing SQL statements and supporting transactions have the following common Data API parameters and AWS CLI options. Some operations support other parameters or options.

Data API operation parameter	AWS CLI command option	Required	Description
`resourceArn`	`--resource-arn`	Yes	The Amazon Resource Name (ARN) of the Aurora DB cluster.
`secretArn`	`--secret-arn`	Yes	The name or ARN of the secret that enables access to the DB cluster.

You can use parameters in Data API calls to `ExecuteStatement` and `BatchExecuteStatement`, and when you run the AWS CLI commands `execute-statement` and `batch-execute-statement`. To use a parameter, you specify a name-value pair in the `SqlParameter` data type. You specify the value with the `Field` data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

JDBC data type	Data API data type
`INTEGER, TINYINT, SMALLINT, BIGINT`	`LONG` (or `STRING`)
`FLOAT, REAL, DOUBLE`	`DOUBLE`
`DECIMAL`	`STRING`
`BOOLEAN, BIT`	`BOOLEAN`
`BLOB, BINARY, LONGVARBINARY, VARBINARY`	`BLOB`
`CLOB`	`STRING`
Other types (including types related to date and time)	`STRING`

Note

You can specify the LONG or STRING data type in your Data API call for LONG values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.

Certain types, such as DECIMAL and TIME, require a hint so that Data API passes String values to the database as the correct type. To use a hint, include values for typeHint in the SqlParameter data type. The possible values for typeHint are the following:

- DATE – The corresponding String parameter value is sent as an object of DATE type to the database. The accepted format is YYYY-MM-DD.
- DECIMAL – The corresponding String parameter value is sent as an object of DECIMAL type to the database.
- JSON – The corresponding String parameter value is sent as an object of JSON type to the database.
- TIME – The corresponding String parameter value is sent as an object of TIME type to the database. The accepted format is HH:MM:SS[.FFF].
- TIMESTAMP – The corresponding String parameter value is sent as an object of TIMESTAMP type to the database. The accepted format is YYYY-MM-DD HH:MM:SS[.FFF].
- UUID – The corresponding String parameter value is sent as an object of UUID type to the database.

  Note

  Currently, Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

Note

For Amazon Aurora PostgreSQL, Data API always returns the Aurora PostgreSQL data type TIMESTAMPTZ in UTC time zone.

Calling RDS Data API with the AWS CLI

You can call RDS Data API (Data API) using the AWS CLI.

The following examples use the AWS CLI for Data API. For more information, see AWS CLI reference for the Data API.

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

> **Note**
>
> The AWS CLI can format responses in JSON.

Topics

Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

> **Important**
>
> Within Data API, a transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, Data API rolls it back automatically.
> MySQL data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each MySQL DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.

In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

For Windows:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```
{
    "transactionId": "ABC1234567890xyz"
}
```

Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

> **Important**
>
> If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.
- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameters` (optional) – The parameters for the SQL statement.
- `--include-result-metadata | --no-include-result-metadata` (optional) – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database` (optional) – The name of the database.

  The `--database` option might not work when you run a SQL statement after running `--sql "use *database_name*;"` in the previous request. We recommend that you use the `--database` option instead of running `--sql "use *database_name*;"` statements.
- `--continue-after-timeout | --no-continue-after-timeout` (optional) – A value that indicates whether to continue running the statement after the call exceeds the Data API timeout interval of 45 seconds. The default is `--no-continue-after-timeout`.

  For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.
- `--format-records-as "JSON"|"NONE"` – An optional value that specifies whether to format the result set as a JSON string. The default is `"NONE"`. For usage information about processing JSON result sets, see Processing RDS Data API query results in JSON format.

The DB cluster returns a response for the call.

> **Note**
>
> The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.
> For Aurora Serverless v1, the maximum number of requests per second is 1,000. For all other supported databases, there is no limit.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
--sql "select * from mytable"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
--sql "select * from mytable"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 0,
    "records": [
        [
            {
                "longValue": 1
            },
            {
                "stringValue": "ValueOne"
            }
        ],
        [
            {
                "longValue": 2
            },
            {
                "stringValue": "ValueTwo"
            }
        ],
        [
            {
                "longValue": 3
            },
            {
                "stringValue": "ValueThree"
            }
        ]
    ]
}
```

The following CLI command runs a single SQL statement in a transaction by specifying the `--transaction-id` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" --parameters "[{\"name\": \"id\",
 \"value\": {\"longValue\": 1}},{\"name\": \"val\", \"value\": {\"stringValue\":
 \"value1\"}}]"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" --parameters "[{\"name\": \"id\",
 \"value\": {\"longValue\": 1}},{\"name\": \"val\", \"value\": {\"stringValue\":
 \"value1\"}}]"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column `job` to column `role`.

> **Important**
>
> For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
--sql "alter table mytable change column job role varchar(100)" --continue-after-
timeout
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
--sql "alter table mytable change column job role varchar(100)" --continue-after-
timeout
```

The following is an example of the response.

```
{
    "generatedFields": [],
    "numberOfRecordsUpdated": 0
}
```

Note

The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see [Returning data from modified rows]() in the PostgreSQL documentation.

Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

> **Tip**
>
> For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.

- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameter-set` (optional) – The parameter sets for the batch operation.
- `--database` (optional) – The name of the database.

The DB cluster returns a response to the call.

> **Note**
>
> There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through Data API is 4 MiB. If the request exceeds this limit, Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.
> The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.
> For Aurora Serverless v1, the maximum number of requests per second is 1,000. For all other supported databases, there is no limit.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" \
--parameter-sets "[[{\"name\": \"id\", \"value\": {\"longValue\": 1}},{\"name\":
 \"val\", \"value\": {\"stringValue\": \"ValueOne\"}}],
[{\"name\": \"id\", \"value\": {\"longValue\": 2}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueTwo\"}}],
[{\"name\": \"id\", \"value\": {\"longValue\": 3}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueThree\"}}]]"
```

For Windows:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" ^
--parameter-sets "[[{\"name\": \"id\", \"value\": {\"longValue\": 1}},{\"name\":
 \"val\", \"value\": {\"stringValue\": \"ValueOne\"}}],
[{\"name\": \"id\", \"value\": {\"longValue\": 2}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueTwo\"}}],
[{\"name\": \"id\", \"value\": {\"longValue\": 3}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueThree\"}}]]"
```

Note

Don't include line breaks in the `--parameter-sets` option.

Committing a SQL transaction

Using the `aws rds-data commit-transaction` CLI command, you can end a SQL transaction that you started with `aws rds-data begin-transaction` and commit the changes.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
    "transactionStatus": "Transaction Committed"
}
```

Rolling back a SQL transaction

Using the `aws rds-data rollback-transaction` CLI command, you can roll back a SQL transaction that you started with `aws rds-data begin-transaction`. Rolling back a transaction cancels its changes.

> **Important**
>
> If the transaction ID has expired, the transaction was rolled back automatically. In this case, an `aws rds-data rollback-transaction` command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following AWS CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
    "transactionStatus": "Rollback Complete"
    }
```

Calling RDS Data API from a Python application

You can call RDS Data API (Data API) from a Python application.

The following examples use the AWS SDK for Python (Boto). For more information about Boto, see the AWS SDK for Python (Boto 3) documentation.

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

Running a SQL query

You can run a SELECT statement and fetch the results with a Python application.

The following example runs a SQL query.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

response1 = rdsData.execute_statement(
            resourceArn = cluster_arn,
            secretArn = secret_arn,
            database = 'mydb',
            sql = 'select * from employees limit 3')

print (response1['records'])
[
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'ROSALEZ'
        },
        {
            'stringValue': 'ALEJANDRO'
        },
        {
            'stringValue': '2016-02-15 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'DOE'
        },
        {
            'stringValue': 'JANE'
        },
        {
            'stringValue': '2014-05-09 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'STILES'
        },
        {
            'stringValue': 'JOHN'
        },
        {
            'stringValue': '2017-09-20 04:34:33.0'
        }
    ]
]
```

Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

Important

If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```
import boto3

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

rdsData = boto3.client('rds-data')

param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}
param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}
paramSet = [param1, param2]
```

```
response2 = rdsData.execute_statement(resourceArn=cluster_arn,
                                      secretArn=secret_arn,
                                      database='mydb',
                                      sql='insert into employees(first_name, last_name)
 VALUES(:firstname, :lastname)',
                                      parameters = paramSet)

print (response2["numberOfRecordsUpdated"])
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

> **Important**
>
> A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
> If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

tr = rdsData.begin_transaction(
     resourceArn = cluster_arn,
     secretArn = secret_arn,
     database = 'mydb')

response3 = rdsData.execute_statement(
     resourceArn = cluster_arn,
     secretArn = secret_arn,
     database = 'mydb',
     sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG')',
    transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

Calling RDS Data API from a Java application

You can call RDS Data API (Data API) from a Java application.

The following examples use the AWS SDK for Java. For more information, see the AWS SDK for Java Developer Guide.

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- Running a SQL query
- Running a SQL transaction
- Running a batch SQL operation

Running a SQL query

You can run a SELECT statement and fetch the results with a Java application.

The following example runs a SQL query.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
import com.amazonaws.services.rdsdata.model.Field;

import java.util.List;

public class FetchResultsExample {
  public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
  public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

  public static void main(String[] args) {
    AWSRDSData rdsData = AWSRDSDataClient.builder().build();

    ExecuteStatementRequest request = new ExecuteStatementRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb")
            .withSql("select * from mytable");

    ExecuteStatementResult result = rdsData.executeStatement(request);

    for (List<Field> fields: result.getRecords()) {
      String stringValue = fields.get(0).getStringValue();
      long numberValue = fields.get(1).getLongValue();

      System.out.println(String.format("Fetched row: string = %s, number = %d",
 stringValue, numberValue));
    }
  }
}
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

> ⚠ **Important**
>
> A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
>
> If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

public class TransactionExample {
  public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
  public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

  public static void main(String[] args) {
    AWSRDSData rdsData = AWSRDSDataClient.builder().build();

    BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb");
    BeginTransactionResult beginTransactionResult =
 rdsData.beginTransaction(beginTransactionRequest);
    String transactionId = beginTransactionResult.getTransactionId();

    ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
```

```
                .withTransactionId(transactionId)
                .withResourceArn(RESOURCE_ARN)
                .withSecretArn(SECRET_ARN)
                .withSql("INSERT INTO test_table VALUES ('hello world!')");
        rdsData.executeStatement(executeStatementRequest);

        CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
                .withTransactionId(transactionId)
                .withResourceArn(RESOURCE_ARN)
                .withSecretArn(SECRET_ARN);
        rdsData.commitTransaction(commitTransactionRequest);
    }
}
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

Important

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
  public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
  public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

  public static void main(String[] args) {
      AWSRDSData rdsData = AWSRDSDataClient.builder().build();

    BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
            .withDatabase("test")
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
            .withParameterSets(Arrays.asList(
                    Arrays.asList(
                            new SqlParameter().withName("string").withValue(new
 Field().withStringValue("Hello")),
                            new SqlParameter().withName("number").withValue(new
 Field().withLongValue(1L))
                    ),
                    Arrays.asList(
                            new SqlParameter().withName("string").withValue(new
 Field().withStringValue("World")),
                            new SqlParameter().withName("number").withValue(new
 Field().withLongValue(2L))
                    )
            ));

    rdsData.batchExecuteStatement(request);
  }
}
```

Controlling Data API timeout behavior

All calls to Data API are synchronous. Suppose that you perform a Data API operation that runs a SQL statement such as `INSERT` or `CREATE TABLE`. If the Data API call returns successfully, the SQL processing is finished when the call returns.

By default, Data API cancels an operation and returns a timeout error if the operation doesn't finish processing within 45 seconds. In that case, the data isn't inserted, the table isn't created, and so on.

You can use Data API to perform long-running operations that can't complete within 45 seconds. If you expect that an operation such as a bulk `INSERT` or a DDL operation on a large table takes longer than 45 seconds, you can specify the `continueAfterTimeout` parameter for the `ExecuteStatement` operation. Your application still receives the timeout error. However, the operation continues running and isn't cancelled. For an example, see Running a SQL transaction.

If the AWS SDK for your programming language has its own timeout period for API calls or HTTP socket connections, make sure that all such timeout periods are more than 45 seconds. For some SDKs, the timeout period is less than 45 seconds by default. We recommend setting any SDK-specific or client-specific timeout periods to at least one minute. Doing so avoids the possibility that your application receives a timeout error while the Data API operation still completes successfully. That way, you can be sure whether to retry the operation or not.

For example, suppose that the SDK returns a timeout error to your application, but the Data API operation still completes within the Data API timeout interval. In that case, retrying the operation might insert duplicate data or otherwise produce incorrect results. The SDK might retry the operation automatically, causing incorrect data without any action from your application.

The timeout interval is especially important for the Java 2 SDK. In that SDK, the API call timeout and the HTTP socket timeout are both 30 seconds by default. Here is an example of setting those timeouts to a higher value:

```
public RdsDataClient createRdsDataClient() {
    return RdsDataClient.builder()
        .region(Region.US_EAST_1) // Change this to your desired Region
        .overrideConfiguration(createOverrideConfiguration())
        .httpClientBuilder(createHttpClientBuilder())
        .credentialsProvider(defaultCredentialsProvider()) // Change this to your
 desired credentials provider
        .build();
}

private static ClientOverrideConfiguration createOverrideConfiguration() {
    return ClientOverrideConfiguration.builder()
        .apiCallTimeout(Duration.ofSeconds(60))
        .build();
}
```

```
private HttpClientBuilder createHttpClientBuilder() {
    return ApacheHttpClient.builder() // Change this to your desired HttpClient
        .socketTimeout(Duration.ofSeconds(60));
}
```

Here is an equivalent example using the asynchronous data client:

```
public static RdsDataAsyncClient createRdsDataAsyncClient() {
    return RdsDataAsyncClient.builder()
        .region(Region.US_EAST_1) // Change this to your desired Region
        .overrideConfiguration(createOverrideConfiguration())
        .credentialsProvider(defaultCredentialsProvider())  // Change this to your
 desired credentials provider
        .build();
}

private static ClientOverrideConfiguration createOverrideConfiguration() {
    return ClientOverrideConfiguration.builder()
        .apiCallAttemptTimeout(Duration.ofSeconds(60))
        .build();
}

private HttpClientBuilder createHttpClientBuilder() {
    return NettyNioAsyncHttpClient.builder() // Change this to your desired
 AsyncHttpClient
        .readTimeout(Duration.ofSeconds(60));
}
```

Using the Java client library for RDS Data API

You can download and use a Java client library for RDS Data API (Data API). This Java client library provides an alternative way to use Data API. Using this library, you can map your client-side classes to Data API requests and responses. This mapping support can ease integration with some specific Java types, such as `Date`, `Time`, and `BigDecimal`.

Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

https://github.com/awslabs/rds-data-api-client-library-java

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with AWS SDK 2.x, use the following:

```
<dependency>
   <groupId>software.amazon.rdsdata</groupId>
   <artifactId>rds-data-api-client-library-java</artifactId>
   <version>2.0.0</version>
</dependency>
```

For version 1.x, which is compatible with AWS SDK 1.x, use the following:

```
<dependency>
    <groupId>software.amazon.rdsdata</groupId>
    <artifactId>rds-data-api-client-library-java</artifactId>
    <version>1.0.8</version>
</dependency>
```

Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table `accounts` with two columns: `accountId` and `name`. You also have the following data transfer object (DTO).

```
public class Account {
    int accountId;
    String name;
    // getters and setters omitted
}
```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameters sets.

```
var account1 = new Account(1, "John");
var account2 = new Account(2, "Mary");
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
         .withParamSets(account1, account2)
         .execute();
```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
         .withParameter("accountId", 3)
         .withParameter("name", "Zhang")
         .execute();
```

The following is another example that works with simple values as input parameters.

```

client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
         .execute();

```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```
List<Account> result = client.forSql("SELECT * FROM accounts")
          .execute()
          .mapToList(Account.class);

Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
          .execute()
          .mapToSingle(Account.class);
```

In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```
int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
          .execute()
          .singleValue(Integer.class);
```

Note

The `mapToList` function converts a SQL result set into a user-defined object list. We don't support using the `.withFormatRecordsAs(RecordsFormatType.JSON)` statement in an `ExecuteStatement` call for the Java client library, because it serves the same purpose. For more information, see Processing RDS Data API query results in JSON format.

Processing RDS Data API query results in JSON format

When you call the ExecuteStatement operation, you can choose to have the query results returned as a string in JSON format. That way, you can use your programming language's JSON parsing capabilities to interpret and reformat the result set. Doing so can help to avoid writing extra code to loop through the result set and interpret each column value.

To request the result set in JSON format, you pass the optional formatRecordsAs parameter with a value of JSON. The JSON-formatted result set is returned in the formattedRecords field of the ExecuteStatementResponse structure.

The BatchExecuteStatement action doesn't return a result set. Thus, the JSON option doesn't apply to that action.

To customize the keys in the JSON hash structure, define column aliases in the result set. You can do so by using the AS clause in the column list of your SQL query.

You might use the JSON capability to make the result set easier to read and map its contents to language-specific frameworks. Because the volume of the ASCII-encoded result set is larger than the default representation, you might choose the default representation for queries that return large numbers of rows or large column values that consume more memory than is available to your application.

Topics

Retrieving query results in JSON format

To receive the result set as a JSON string, include .withFormatRecordsAs(RecordsFormatType.JSON) in the ExecuteStatement call. The return value comes back as a JSON string in the formattedRecords field. In this case, the columnMetadata is null. The column labels are the keys of the object that represents each row. These column names are repeated for each row in the result set. The column values are quoted strings, numeric values, or special values representing true, false, or null. Column metadata such as length constraints and the precise type for numbers and strings isn't preserved in the JSON response.

If you omit the .withFormatRecordsAs() call or specify a parameter of NONE, the result set is returned in binary format using the Records and columnMetadata fields.

Data Type Mapping

The SQL values in the result set are mapped to a smaller set of JSON types. The values are represented in JSON as strings, numbers, and some special constants such as true, false, and null. You can convert these values into variables in your application, using strong or weak typing as appropriate for your programming language.

JDBC data type	JSON data type
INTEGER, TINYINT, SMALLINT, BIGINT	Number by default. String if the LongReturnType option is set to STRING.
FLOAT, REAL, DOUBLE	Number
DECIMAL	String by default. Number if the DecimalReturnType option is set to DOUBLE_OR_LONG .
STRING	String
BOOLEAN, BIT	Boolean
BLOB, BINARY, VARBINARY , LONGVARBINARY	String in base64 encoding.
CLOB	String
ARRAY	Array
NULL	null
Other types (including types related to date and time)	String

Troubleshooting

The JSON response is limited to 10 megabytes. If the response is larger than this limit, your program receives a BadRequestException error. In this case, you can resolve the error using one of the following techniques:

- Reduce the number of rows in the result set. To do so, add a LIMIT clause. You might split a large result set into multiple smaller ones by submitting several queries with LIMIT and OFFSET clauses.

  If the result set includes rows that are filtered out by application logic, you can remove those rows from the result set by adding more conditions in the WHERE clause.
- Reduce the number of columns in the result set. To do so, remove items from the select list of the query.
- Shorten the column labels by using column aliases in the query. Each column name is repeated in the JSON string for each row in the result set. Thus, a query result with long column names and many rows could exceed the size limit. In particular, use column aliases for complicated expressions to avoid having the entire expression repeated in the JSON string.
- Although with SQL you can use column aliases to produce a result set having more than one column with the same name, duplicate key names aren't allowed in JSON. The RDS Data API returns an error if you request the result set in JSON format and more than one column has the same name. Thus, make sure that all the column labels have unique names.

Examples

The following Java examples show how to call ExecuteStatement with the response as a JSON-formatted string, then interpret the result set. Substitute the appropriate values for the *databaseName*, *secretStoreArn*, and *clusterArn* parameters.

The following Java example demonstrates a query that returns a decimal numeric value in the result set. The assertThat calls test that the fields of the response have the expected properties based on the rules for JSON result sets.

This example works with the following schema and sample data:

```
create table test_simplified_json (a float);
insert into test_simplified_json values(10.0);
```

```
public void JSON_result_set_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
      .withDatabase(databaseName)
      .withSecretArn(secretStoreArn)
      .withResourceArn(clusterArn)
      .withSql(sql)
      .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request);
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":10.0}]
```

The `Records` and `ColumnMetadata` fields in the response are both null, due to the presence of the JSON result set.

The following Java example demonstrates a query that returns an integer numeric value in the result set. The example calls `getFormattedRecords` to return only the JSON-formatted string and ignore the other response fields that are blank or null. The example deserializes the result into a structure representing a list of records. Each record has fields whose names correspond to the column aliases from the result set. This technique simplifies the code that parses the result set. Your application doesn't have to loop through the rows and columns of the result set and convert each value to the appropriate type.

This example works with the following schema and sample data:

```
create table test_simplified_json (a int);
insert into test_simplified_json values(17);
```

```
public void JSON_deserialization_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
      .withDatabase(databaseName)
      .withSecretArn(secretStoreArn)
      .withResourceArn(clusterArn)
      .withSql(sql)
      .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request)
      .getFormattedRecords();
/* Turn the result set into a Java object, a list of records.
   Each record has a field 'a' corresponding to the column
   labelled 'a' in the result set. */
    private static class Record { public int a; }
    var recordsList = new ObjectMapper().readValue(
        response, new TypeReference<List<Record>>() {
        });
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":17}]
```

To retrieve the a column of result row 0, the application would refer to `recordsList.get(0).a`.

In contrast, the following Java example shows the kind of code that's required to construct a data structure holding the result set when you don't use the JSON format. In this case, each row of the result set contains fields with information about a single user. Building a data structure to represent the result set requires looping through the rows. For each row, the code retrieves the value of each field, performs an appropriate type conversion, and assigns the result to the corresponding field in the object representing the row. Then the code adds the object representing each user to the data structure representing the entire result set. If the query was changed to reorder, add, or remove fields in the result set, the application code would have to change also.

```
/* Verbose result-parsing code that doesn't use the JSON result set format */
for (var row: response.getRecords()) {
    var user = User.builder()
      .userId(row.get(0).getLongValue())
      .firstName(row.get(1).getStringValue())
      .lastName(row.get(2).getStringValue())
      .dob(Instant.parse(row.get(3).getStringValue()))
      .build();
    result.add(user);
  }
```

The following sample values show the values of the `formattedRecords` field for result sets with different numbers of columns, column aliases, and column data types.

If the result set includes multiple rows, each row is represented as an object that is an array element. Each column in the result set becomes a key in the object. The keys are repeated for each row in the result set. Thus, for result sets consisting of many rows and columns, you might need to define short column aliases to avoid exceeding the length limit for the entire response.

This example works with the following schema and sample data:

```
create table sample_names (id int, name varchar(128));
insert into sample_names values (0, "Jane"), (1, "Mohan"), (2, "Maria"), (3, "Bruce"),
 (4, "Jasmine");
```

```
[{"id":0,"name":"Jane"},{"id":1,"name":"Mohan"},
{"id":2,"name":"Maria"},{"id":3,"name":"Bruce"},{"id":4,"name":"Jasmine"}]
```

If a column in the result set is defined as an expression, the text of the expression becomes the JSON key. Thus, it's typically convenient to define a descriptive column alias for each expression in the select list of the query. For example, the following query includes expressions such as function calls and arithmetic operations in its select list.

```
select count(*), max(id), 4+7 from sample_names;
```

Those expressions are passed through to the JSON result set as keys.

```
[{"count(*)":5,"max(id)":4,"4+7":11}]
```

Adding AS columns with descriptive labels makes the keys simpler to interpret in the JSON result set.

```
select count(*) as rows, max(id) as largest_id, 4+7 as addition_result from
 sample_names;
```

With the revised SQL query, the column labels defined by the AS clauses are used as the key names.

```
[{"rows":5,"largest_id":4,"addition_result":11}]
```

The value for each key-value pair in the JSON string can be a quoted string. The string might contain unicode characters. If the string contains escape sequences or the " or \ characters, those characters are preceded by backslash escape characters. The following examples of JSON strings demonstrate these possibilities. For example, the `string_with_escape_sequences` result contains the special characters backspace, newline, carriage return, tab, form feed, and \.

```
[{"quoted_string":"hello"}]
[{"unicode_string":"####"}]
[{"string_with_escape_sequences":"\b \n \r \t \f \\ '"}]
```

The value for each key-value pair in the JSON string can also represent a number. The number might be an integer, a floating-point value, a negative value, or a value represented as exponential notation. The following examples of JSON strings demonstrate these possibilities.

```
[{"integer_value":17}]
[{"float_value":10.0}]
[{"negative_value":-9223372036854775808,"positive_value":9223372036854775807}]
[{"very_small_floating_point_value":4.9E-324,"very_large_floating_point_value":1.79769313486231
```

Boolean and null values are represented with the unquoted special keywords `true`, `false`, and `null`. The following examples of JSON strings demonstrate these possibilities.

```
[{"boolean_value_1":true,"boolean_value_2":false}]
[{"unknown_value":null}]
```

If you select a value of a BLOB type, the result is represented in the JSON string as a base64-encoded value. To convert the value back to its original representation, you can use the appropriate decoding function in your application's language. For example, in Java you call the function `Base64.getDecoder().decode()`. The following sample output shows the result of selecting a BLOB value of `hello world` and returning the result set as a JSON string.

```
[{"blob_column":"aGVsbG8gd29ybGQ="}]
```

The following Python example shows how to access the values from the result of a call to the Python `execute_statement` function. The result set is a string value in the field `response['formattedRecords']`. The code turns the JSON string into a data structure by calling the `json.loads` function. Then each row of the result set is a list element within the data structure, and within each row you can refer to each field of the result set by name.

```
import json
```

```
result = json.loads(response['formattedRecords'])
print (result[0]["id"])
```

The following JavaScript example shows how to access the values from the result of a call to the JavaScript `executeStatement` function. The result set is a string value in the field `response.formattedRecords`. The code turns the JSON string into a data structure by calling the `JSON.parse` function. Then each row of the result set is an array element within the data structure, and within each row you can refer to each field of the result set by name.

```
<script>
    const result = JSON.parse(response.formattedRecords);
    document.getElementById("display").innerHTML = result[0].id;
</script>
```

Troubleshooting RDS Data API issues

Use the following sections, titled with common error messages, to help troubleshoot problems that you have with RDS Data API (Data API).

Topics

Transaction <transaction_ID> is not found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is appended to the error message, and is one of the following:

- Transaction may be expired.

  Make sure that each transactional call runs within three minutes of the previous one.

  It's also possible that the specified transaction ID wasn't created by a BeginTransaction call. Make sure that your call has a valid transaction ID.

- One previous call resulted in a termination of your transaction.

The transaction was already ended by your CommitTransaction or RollbackTransaction call.

- Transaction has been aborted due to an error from a previous call.

  Check whether your previous calls have thrown any exceptions.

For information about running transactions, see Calling RDS Data API.

Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the result set returned by the database.

To solve this issue, make sure that each row in a result set is 64 KB or less.

Database response exceeded size limit

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple ExecuteStatement calls with the LIMIT clause in your query.

For more information about the LIMIT clause, see SELECT syntax in the MySQL documentation.

HttpEndpoint is not enabled for cluster <cluster_ID>

Check the following potential causes for this issue:

- The Aurora DB cluster doesn't support Data API. For example, for Aurora MySQL, you can only use Data API with Aurora Serverless v1. For information about the types of DB clusters RDS Data API supports, see the section called “Region and version availability”.
- Data API isn't enabled for the Aurora DB cluster. To use Data API with an Aurora DB cluster, Data API must be enabled for the DB cluster. For information about enabling Data API, see Enabling RDS Data API.
- The DB cluster was renamed after Data API was enabled for it. In that case, turn off Data API for that cluster and then enable it again.

- The ARN you specified doesn't precisely match the ARN of the cluster. Check that the ARN returned from another source or constructed by program logic matches the ARN of the cluster exactly. For example, make sure that the ARN you use has the correct letter case for all alphabetic characters.

Logging RDS Data API calls with AWS CloudTrail

RDS Data API (Data API) is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Data API information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported activity (management events) occurs in Data API, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent management events in your AWS account. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide.*

For an ongoing record of events in your AWS account, including events for Data API, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the *AWS CloudTrail User Guide*:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail

- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

All Data API operations are logged by CloudTrail and documented in the *Amazon RDS data service API reference*. For example, calls to the `BatchExecuteStatement`, `BeginTransaction`, `CommitTransaction`, and `ExecuteStatement` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

Including and excluding Data API events from an AWS CloudTrail trail

Most Data API users rely on the events in an AWS CloudTrail trail to provide a record of Data API operations. Event data doesn't reveal the database name, schema name, or SQL statements in requests to the Data API. However, knowing which user made a type of call against a specific DB cluster at a given time can help to detect anomalous access patterns.

Including Data API events in an AWS CloudTrail trail

For Aurora PostgreSQL Serverless v2 and provisioned databases, the following Data API operations are logged to AWS CloudTrail as *data events*. Data events are high-volume data-plane API operations that CloudTrail doesn't log by default. Additional charges apply for data events. For information about CloudTrail pricing, see AWS CloudTrail Pricing.

- BatchExecuteStatement
- BeginTransaction
- CommitTransaction
- ExecuteStatement
- RollbackTransaction

You can use the CloudTrail console,AWS CLI, or CloudTrail API operations to log these Data API operations. In the CloudTrail console, choose **RDS Data API - DB Cluster** for the Data event type. For more information, see Logging data events with the AWS Management Console in the *AWS CloudTrail User Guide*.

Using the AWS CLI, run the `aws cloudtrail put-event-selectors` command to log these Data API operations for your trail. To log all Data API events on DB clusters, specify `AWS::RDS::DBCluster` for the resource type. The following example logs all Data API events on DB clusters. For more information, see Logging data events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

```
aws cloudtrail put-event-selectors --trail-name trail_name --advanced-event-selectors \
'{
   "Name": "RDS Data API Selector",
   "FieldSelectors": [
      {
         "Field": "eventCategory",
         "Equals": [
            "Data"
         ]
      },
      {
         "Field": "resources.type",
         "Equals": [
            "AWS::RDS::DBCluster"
         ]
      }
   ]
}'
```

You can configure advanced event selectors to additionally filter on the `readOnly`, `eventName`, and `resources.ARN` fields. For more information on these fields, see AdvancedFieldSelector.

Excluding Data API events from an AWS CloudTrail trail (Aurora Serverless v1 only)

For Aurora Serverless v1, Data API events are management events. By default, all Data API events are included in an AWS CloudTrail trail. However, because Data API can generate a large number of events, you might want to exclude these events from your CloudTrail trail. The **Exclude Amazon RDS Data API events** setting excludes all Data API events from the trail. You can't exclude specific Data API events.

To exclude Data API events from a trail, do the following:

- In the CloudTrail console, choose the **Exclude Amazon RDS Data API events** setting when you create a trail or update a trail.
- In the CloudTrail API, use the PutEventSelectors operation. If you're using advanced event selectors, you can exclude Data API events by setting the `eventSource` field not equal to `rdsdata.amazonaws.com`. If you're using basic event selectors, you can exclude Data API events by setting the value of the `ExcludeManagementEventSources` attribute to `rdsdata.amazonaws.com`. For more information, see Logging events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

⚠ **Warning**

Excluding Data API events from a CloudTrail log can obscure Data API actions. Be cautious when giving principals the `cloudtrail:PutEventSelectors` permission that is required to perform this operation.

You can turn off this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording Data API events. However, it can't recover Data API events that occurred while the exclusion was effective.

When you exclude Data API events by using the console or API, the resulting CloudTrail `PutEventSelectors` API operation is also logged in your CloudTrail logs. If Data API events don't appear in your CloudTrail logs, look for a `PutEventSelectors` event with the `ExcludeManagementEventSources` attribute set to `rdsdata.amazonaws.com`.

For more information, see Logging management events for trails in the *AWS CloudTrail User Guide*.

Understanding Data API log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

Aurora PostgreSQL Serverless v2 and provisioned

The following example shows a CloudTrail log entry that demonstrates the `ExecuteStatement` operation for Aurora PostgreSQL Serverless v2 and provisioned databases. For these databases, all Data API events are data events where the event source is **rdsdataapi.amazonaws.com** and the event type is **Rds Data Service**.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T00:49:34Z",
    "eventSource": "rdsdataapi.amazonaws.com",
    "eventName": "ExecuteStatement",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",
    "requestParameters": {
        "continueAfterTimeout": false,
        "database": "**********",
        "includeResultMetadata": false,
        "parameters": [],
        "resourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-database-1",
        "schema": "**********",
        "secretArn": "arn:aws:secretsmanager:us-
east-1:123456789012:secret:dataapisecret-ABC123",
        "sql": "**********"
    },
    "responseElements": null,
    "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",
    "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",
    "eventType": "Rds Data Service",
    "recipientAccountId": "123456789012"
}
```

Aurora Serverless v1

The following example shows how the preceding example CloudTrail log entry appears for Aurora Serverless v1. For Aurora Serverless v1, all events are management events where the event source is **rdsdata.amazonaws.com** and the event type is **AwsApiCall**.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T00:49:34Z",
    "eventSource": "rdsdata.amazonaws.com",
    "eventName": "ExecuteStatement",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",
    "requestParameters": {
        "continueAfterTimeout": false,
        "database": "**********",
        "includeResultMetadata": false,
        "parameters": [],
        "resourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-database-1",
        "schema": "**********",
        "secretArn": "arn:aws:secretsmanager:us-
east-1:123456789012:secret:dataapisecret-ABC123",
        "sql": "**********"
    },
    "responseElements": null,
    "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",
    "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

Using the Aurora query editor

The Aurora query editor lets you run SQL statements on your Aurora DB cluster through the AWS Management Console. You can run SQL queries, data manipulation (DML) statements, and data definition (DDL) statements. Using the console interface lets you perform database maintenance, produce reports, and conduct SQL experiments. You can avoid setting up the network configuration to connect to your DB cluster from a separate client system such as an EC2 instance or a laptop computer.

The query editor requires an Aurora DB cluster with RDS Data API (Data API) enabled. For information about DB clusters that support Data API and how to enable it, see Using RDS Data API. The SQL that you can run is subject to the Data API limitations. For more information, see the section called “Limitations”.

Availability of the query editor

The query editor is available for Aurora DB clusters using Aurora MySQL and Aurora PostgreSQL engine versions that support Data API, and in the AWS Regions where Data API is available. For more information, see Supported Regions and Aurora DB engines for RDS Data API.

Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the `AmazonRDSDataFullAccess` policy, a predefined AWS Identity and Access Management (IAM) policy, to that user.

Note

Make sure to use the same user name and password when you create the IAM user as you did for the database user, such as the administrative user name and password. For more information, see Creating an IAM user in your AWS account in the *AWS Identity and Access Management User Guide*.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

The following policy provides the minimum required permissions for a user to access the query editor.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "QueryEditor0",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue",
                "secretsmanager:PutResourcePolicy",
                "secretsmanager:PutSecretValue",
                "secretsmanager:DeleteSecret",
                "secretsmanager:DescribeSecret",
                "secretsmanager:TagResource"
            ],
            "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*"
        },
        {
            "Sid": "QueryEditor1",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetRandomPassword",
                "tag:GetResources",
                "secretsmanager:CreateSecret",
                "secretsmanager:ListSecrets",
                "dbqms:CreateFavoriteQuery",
                "dbqms:DescribeFavoriteQueries",
                "dbqms:UpdateFavoriteQuery",
                "dbqms:DeleteFavoriteQueries",
                "dbqms:GetQueryString",
                "dbqms:CreateQueryHistory",
                "dbqms:UpdateQueryHistory",
                "dbqms:DeleteQueryHistory",
                "dbqms:DescribeQueryHistory",
                "rds-data:BatchExecuteStatement",
                "rds-data:BeginTransaction",
                "rds-data:CommitTransaction",
                "rds-data:ExecuteStatement",
                "rds-data:RollbackTransaction"
            ],
            "Resource": "*"
        }
    ]
}
```

For information about creating an IAM policy, see Creating IAM policies in the *AWS Identity and Access Management User Guide*.

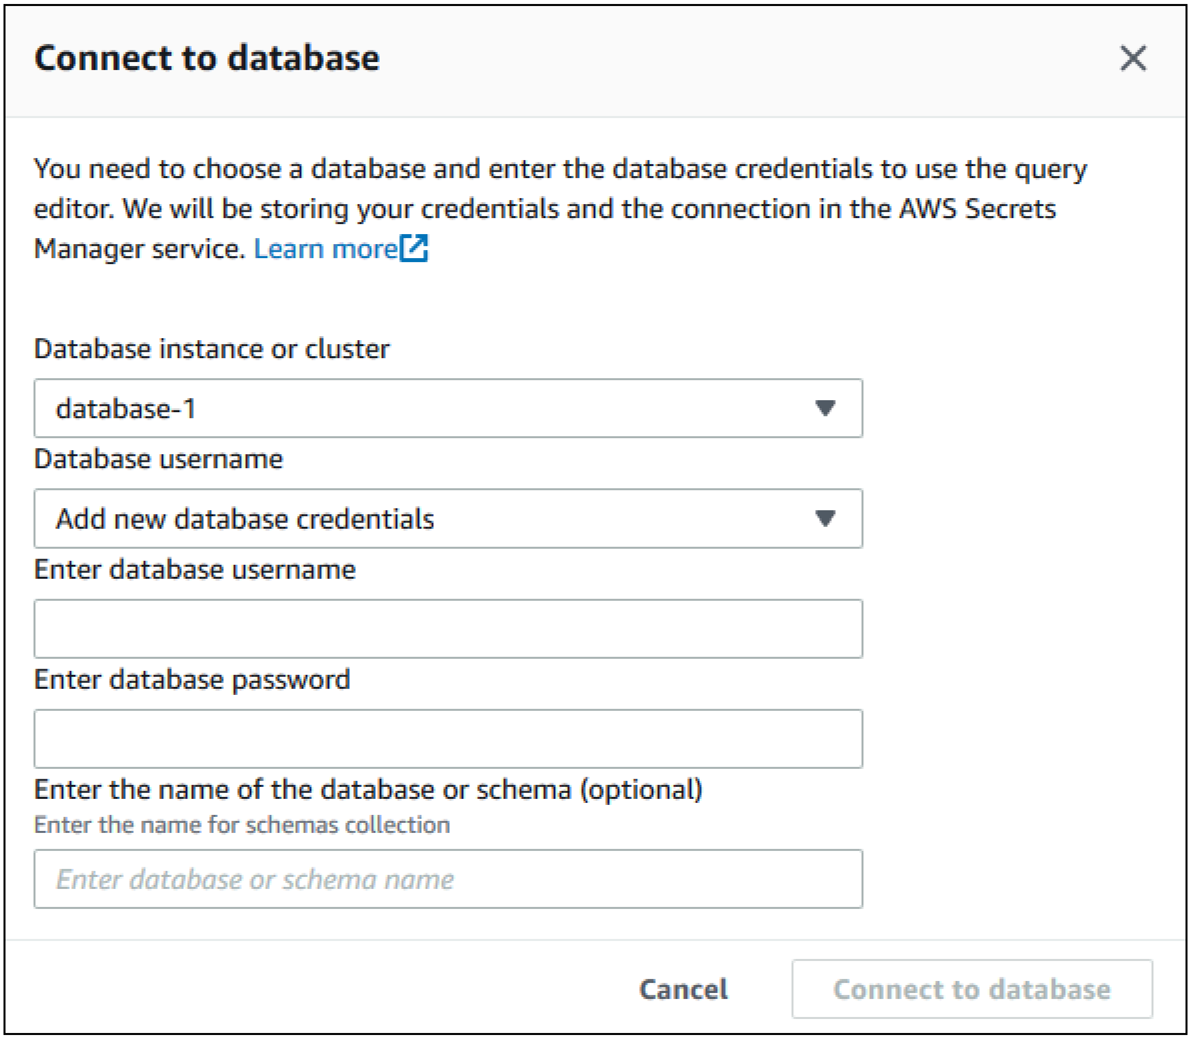
For information about adding an IAM policy to a user, see Adding and removing IAM identity permissions in the *AWS Identity and Access Management User Guide*.

Running queries in the query editor

You can run SQL statements on an Aurora DB cluster in the query editor. The SQL that you can run is subject to the Data API limitations. For more information, see the section called “Limitations”.

To run a query in the query editor

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora DB clusters that you want to query.
3. In the navigation pane, choose **Databases**.
4. Choose the Aurora DB cluster that you want to run SQL queries on.
5. For **Actions**, choose **Query**. If you haven't connected to the database before, the **Connect to database** page opens.



Connect to database

You need to choose a database and enter the database credentials to use the query editor. We will be storing your credentials and the connection in the AWS Secrets Manager service. Learn more

Database instance or cluster: database-1

Database username: Add new database credentials

Enter database username

Enter database password

Enter the name of the database or schema (optional)

Enter the name for schemas collection

Enter database or schema name

6. Enter the following information:

   a. For **Database instance or cluster**, choose the Aurora DB cluster that you want to run SQL queries on.

   b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.

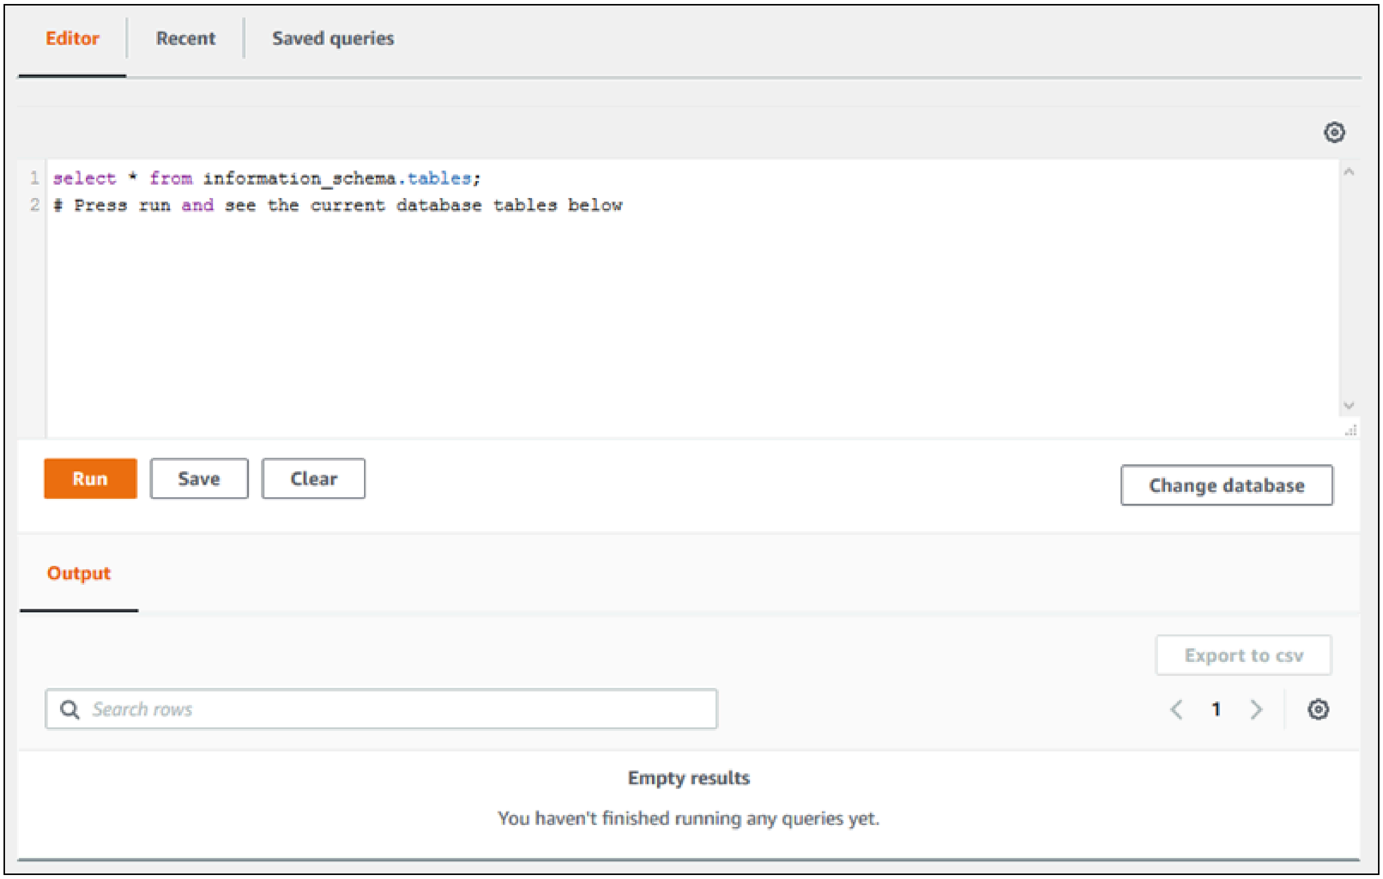
   c. For **Enter database password**, enter the password for the database user that you chose.

   d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.

   e. Choose **Connect to database**.

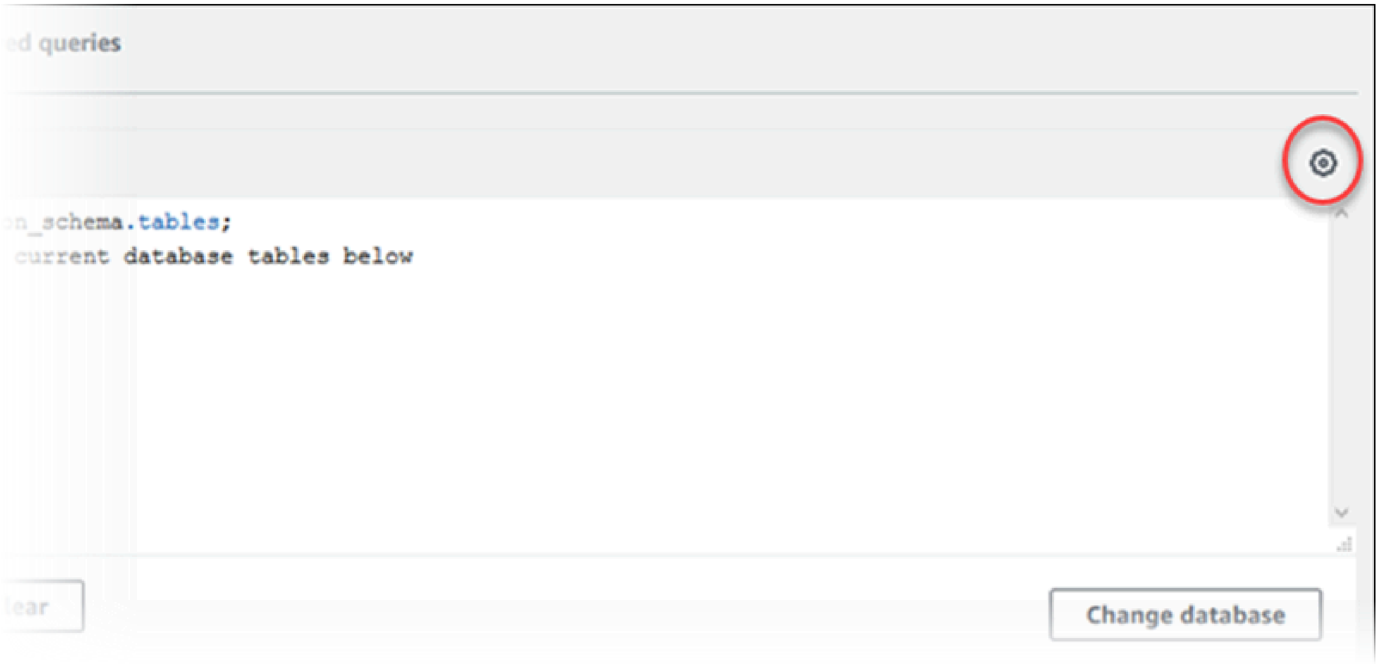
> **Note**
>
> If your connection is successful, your connection and authentication information are stored in AWS Secrets Manager. You don't need to enter the connection information again.

7. In the query editor, enter the SQL query that you want to run on the database.



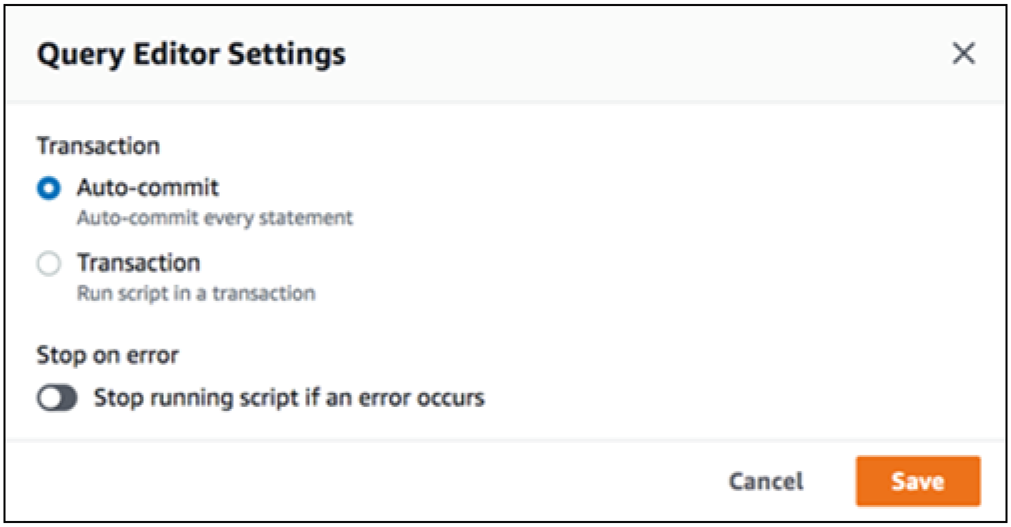
```
select * from information_schema.tables;
# Press run and see the current database tables below
```

Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.



```
n_schema.tables;
current database tables below
```

The **Query Editor Settings** window appears.



Query Editor Settings ✕

Transaction

● Auto-commit
Auto-commit every statement

○ Transaction
Run script in a transaction

Stop on error

Stop running script if an error occurs

If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

> **Note**
>
> In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include `COMMIT` and `ROLLBACK` statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

   After running the query, save it to **Saved queries** by choosing **Save**.

   Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (`dbqms`) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.

The following DBQMS actions are supported:

Topics

- CreateFavoriteQuery
- CreateQueryHistory
- CreateTab
- DeleteFavoriteQueries
- DeleteQueryHistory
- DeleteTab
- DescribeFavoriteQueries

- DescribeQueryHistory
- DescribeTabs
- GetQueryString
- UpdateFavoriteQuery
- UpdateQueryHistory
- UpdateTab

CreateFavoriteQuery

Save a new favorite query. Each user can create up to 1000 saved queries. This limit is subject to change in the future.

CreateQueryHistory

Save a new query history entry.

CreateTab

Save a new query tab. Each user can create up to 10 query tabs.

DeleteFavoriteQueries

Delete one or more saved queries.

DeleteQueryHistory

Delete query history entries.

DeleteTab

Delete query tab entries.

DescribeFavoriteQueries

List saved queries created by a user in a given account.

DescribeQueryHistory

List query history entries.

DescribeTabs

List query tabs created by a user in a given account.

GetQueryString

Retrieve full query text from a query ID.

UpdateFavoriteQuery

Update the query string, description, name, or expiration date.

UpdateQueryHistory

Update the status of query history.

UpdateTab

Update the query tab name and query string.

Using Amazon Aurora machine learning

By using Amazon Aurora machine learning, you can integrate your Aurora DB cluster with one of the following AWS machine learning services, depending on your needs. They each support specific machine learning use cases.

Amazon Bedrock

Amazon Bedrock is a fully managed service that makes leading foundation models from AI companies available through an API, along with developer tooling to help build and scale generative AI applications. With Amazon Bedrock, you pay to run inference on any of the third-party foundation models. Pricing is based on the volume of input tokens and output tokens, and on whether you have purchased provisioned throughput for the model. For more information, see What is Amazon Bedrock? in the *Amazon Bedrock User Guide*.

Amazon Comprehend

Amazon Comprehend is a managed natural language processing (NLP) service that's used to extract insights from documents. With Amazon Comprehend, you can deduce sentiment based on the content of documents, by analyzing entities, key phrases, language, and other features. To learn more, see What is Amazon Comprehend? in the *Amazon Comprehend Developer Guide*.

SageMaker

Amazon SageMaker is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready for use in production, it can be deployed to the Amazon SageMaker hosted environment. For more information, see What Is Amazon SageMaker? in the *Amazon SageMaker Developer Guide*.

Using Amazon Comprehend with your Aurora DB cluster has less preliminary setup than using SageMaker. If you're new to AWS machine learning, we recommend that you start by exploring Amazon Comprehend.

Topics

Using Amazon Aurora machine learning with Aurora MySQL

By using Amazon Aurora machine learning with your Aurora MySQL DB cluster, you can use Amazon Bedrock, Amazon Comprehend, or Amazon SageMaker, depending on your needs. They each support different machine learning use cases.

Contents

Requirements for using Aurora machine learning with Aurora MySQL

AWS machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Bedrock, Amazon Comprehend, and SageMaker. Before trying to set up your Aurora MySQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The machine learning services must be running in the same AWS Region as your Aurora MySQL DB cluster. You can't use machine learning services from an Aurora MySQL DB cluster in a different Region.
- If your Aurora MySQL DB cluster is in a different virtual public cloud (VPC) from your Amazon Bedrock, Amazon Comprehend, or SageMaker service, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Control traffic to your AWS resources using security groups in the *Amazon VPC User Guide*.
- You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see Database engine updates for Amazon Aurora MySQL.
- Your Aurora MySQL DB cluster must use a custom DB cluster parameter group. At the end of the setup process for each Aurora machine learning service that you want to use, you add the Amazon Resource Name (ARN) of the associated IAM role that was created for the service. We recommend that you create a custom DB cluster parameter group for your Aurora MySQL in advance and configure your Aurora MySQL DB cluster to use it so that it's ready for you to modify at the end of the setup process.
- For SageMaker:
  - The machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora MySQL DB cluster, make sure to have the ARN of the SageMaker endpoint available. The data scientists on your team are likely best able to handle working with SageMaker to prepare the models and handle the other such tasks. To get started with Amazon SageMaker, see Get Started with Amazon SageMaker. For more information about inferences and endpoints, see Real-time inference.
  - To use SageMaker with your own training data, you must set up an Amazon S3 bucket as part of your Aurora MySQL configuration for Aurora machine learning. To do so, you follow the same general process as for setting up the SageMaker integration. For a summary of this optional setup process, see Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional).

- For Aurora global databases, you set up the Aurora machine learning services that you want to use in all AWS Regions that make up your Aurora global database. For example, if you want to use Aurora machine learning with SageMaker for your Aurora global database, you do the following for every Aurora MySQL DB cluster in every AWS Region:
  - Set up the Amazon SageMaker services with the same SageMaker training models and endpoints. These must also use the same names.
  - Create the IAM roles as detailed in Setting up your Aurora MySQL DB cluster to use Aurora machine learning.
  - Add the ARN of the IAM role to the custom DB cluster parameter group for each Aurora MySQL DB cluster in every AWS Region.

  These tasks require that Aurora machine learning is available for your version of Aurora MySQL in all AWS Regions that make up your Aurora global database.

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions.

- For information on version and Region availability for Amazon Comprehend and Amazon SageMaker with Aurora MySQL, see Aurora machine learning with Aurora MySQL.
- Amazon Bedrock is supported only on Aurora MySQL version 3.06 and higher.

  For information on Region availability for Amazon Bedrock, see Supported models in Amazon Bedrock in the *Amazon Bedrock User Guide*.

Supported features and limitations of Aurora machine learning with Aurora MySQL

When using Aurora MySQL with Aurora machine learning, the following limitations apply:

- The Aurora machine learning extension doesn't support vector interfaces.
- Aurora machine learning integrations aren't supported when used in a trigger.
- Aurora machine learning functions aren't compatible with binary logging (binlog) replication.
  - The setting `--binlog-format=STATEMENT` throws an exception for calls to Aurora machine learning functions.

  - Aurora machine learning functions are nondeterministic, and nondeterministic stored functions aren't compatible with the binlog format.

  For more information, see Binary Logging Formats in the MySQL documentation.

- Stored functions that call tables with generated-always columns aren't supported. This applies to any Aurora MySQL stored function. To learn more about this column type, see CREATE TABLE and Generated Columns in the MySQL documentation.
- Amazon Bedrock functions don't support `RETURNS JSON`. You can use `CONVERT` or `CAST` to convert from `TEXT` to `JSON` if needed.
- Amazon Bedrock doesn't support batch requests.
- Aurora MySQL supports any SageMaker endpoint that reads and writes the comma-separated value (CSV) format, through a `ContentType` of `text/csv`. This format is accepted by the following built-in SageMaker algorithms:
  - Linear Learner
  - Random Cut Forest
  - XGBoost

  To learn more about these algorithms, see Choose an Algorithm in the *Amazon SageMaker Developer Guide*.

Setting up your Aurora MySQL DB cluster to use Aurora machine learning

In the following topics, you can find separate setup procedures for each of these Aurora machine learning services.

Topics

- Granting access to SageMaker functions

Setting up your Aurora MySQL DB cluster to use Amazon Bedrock

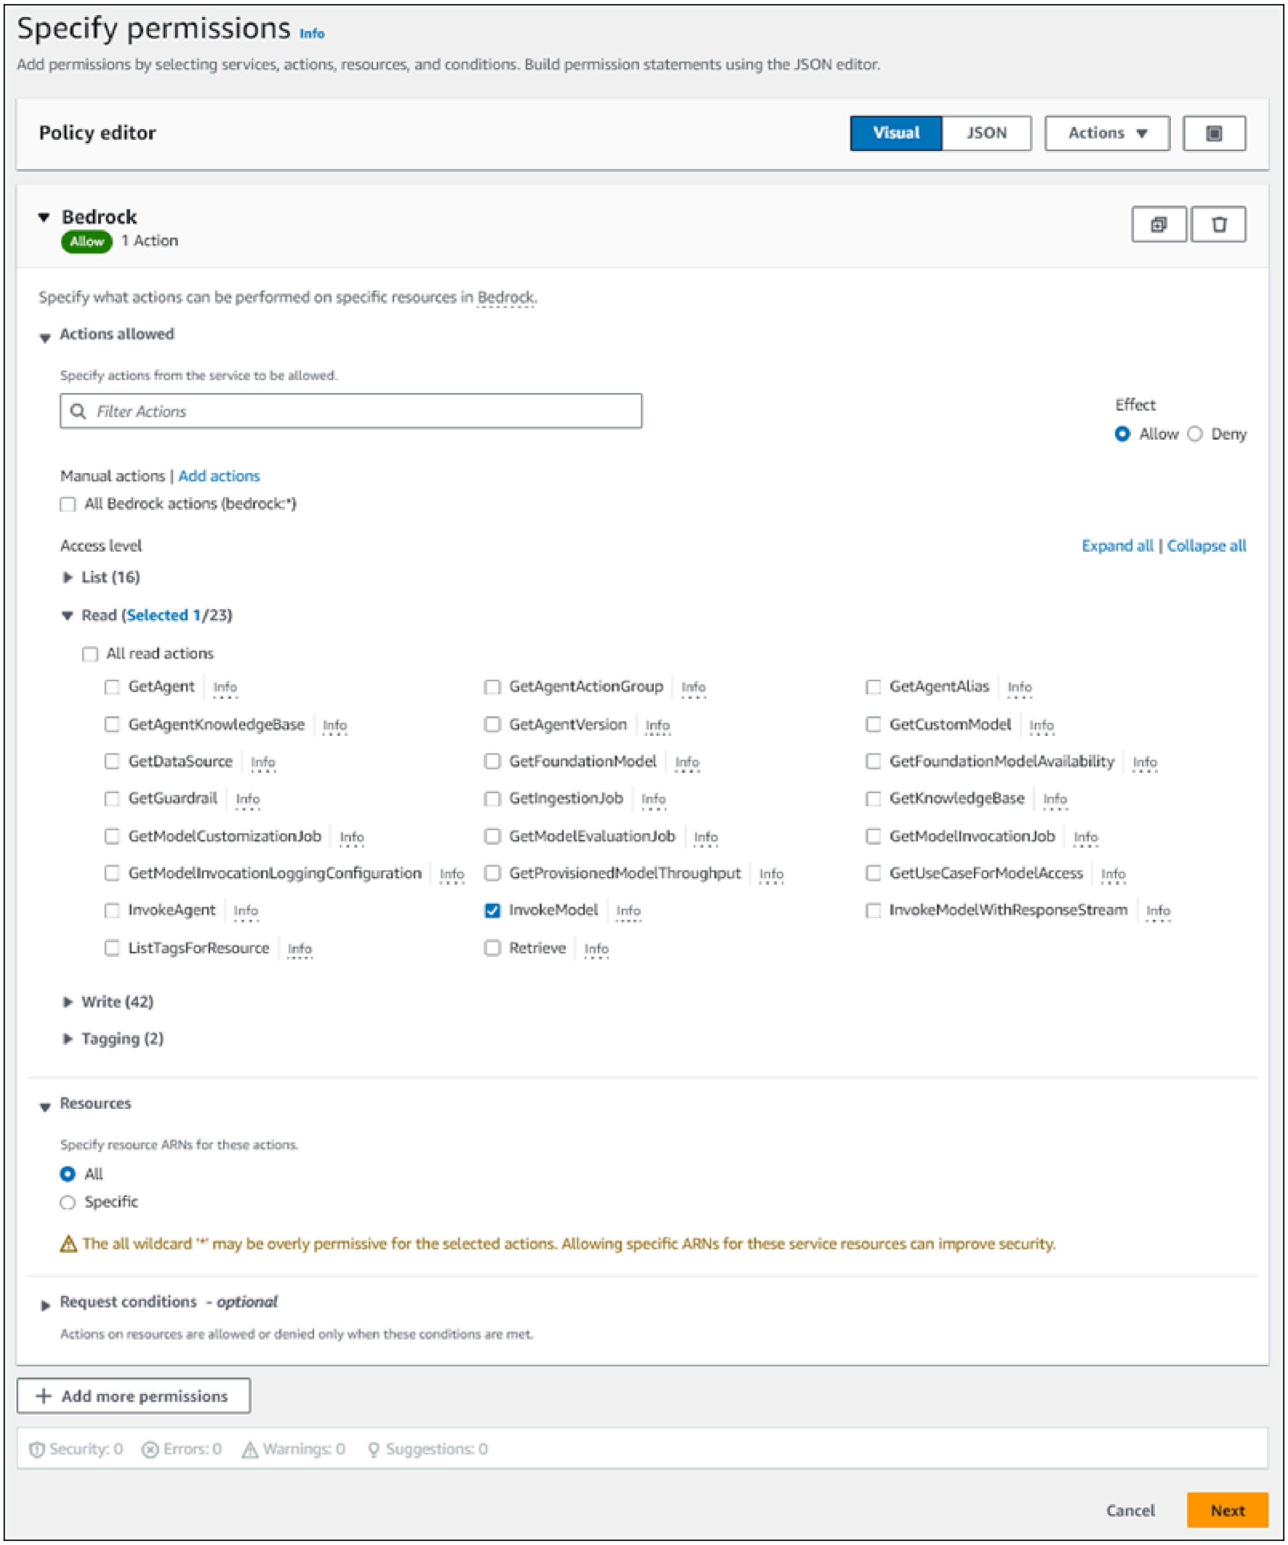
Aurora machine learning relies on AWS Identity and Access Management (IAM) roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Bedrock services. The following procedures create an IAM permission policy and role so that your DB cluster can integrate with Amazon Bedrock.

To create the IAM policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Policies** in the navigation pane.
3. Choose **Create a policy**.
4. On the **Specify permissions** page, for **Select a service**, choose **Bedrock**.

   The Amazon Bedrock permissions display.
5. Expand **Read**, then select **InvokeModel**.
6. For **Resources**, select **All**.

   The **Specify permissions** page should resemble the following figure.



Specify permissions Info

Add permissions by selecting services, actions, resources, and conditions. Build permission statements using the JSON editor.

Policy editor

▼ Bedrock

Allow 1 Action

Specify what actions can be performed on specific resources in Bedrock.

▼ Actions allowed

Specify actions from the service to be allowed.

Effect

● Allow ○ Deny

● All

○ Specific

⚠ The all wildcard '*' may be overly permissive for the selected actions. Allowing specific ARNs for these service resources can improve security.

▶ Request conditions - *optional*

Actions on resources are allowed or denied only when these conditions are met.

7. Choose **Next**.

8. On the **Review and create** page, enter a name for your policy, for example **`BedrockInvokeModel`**.

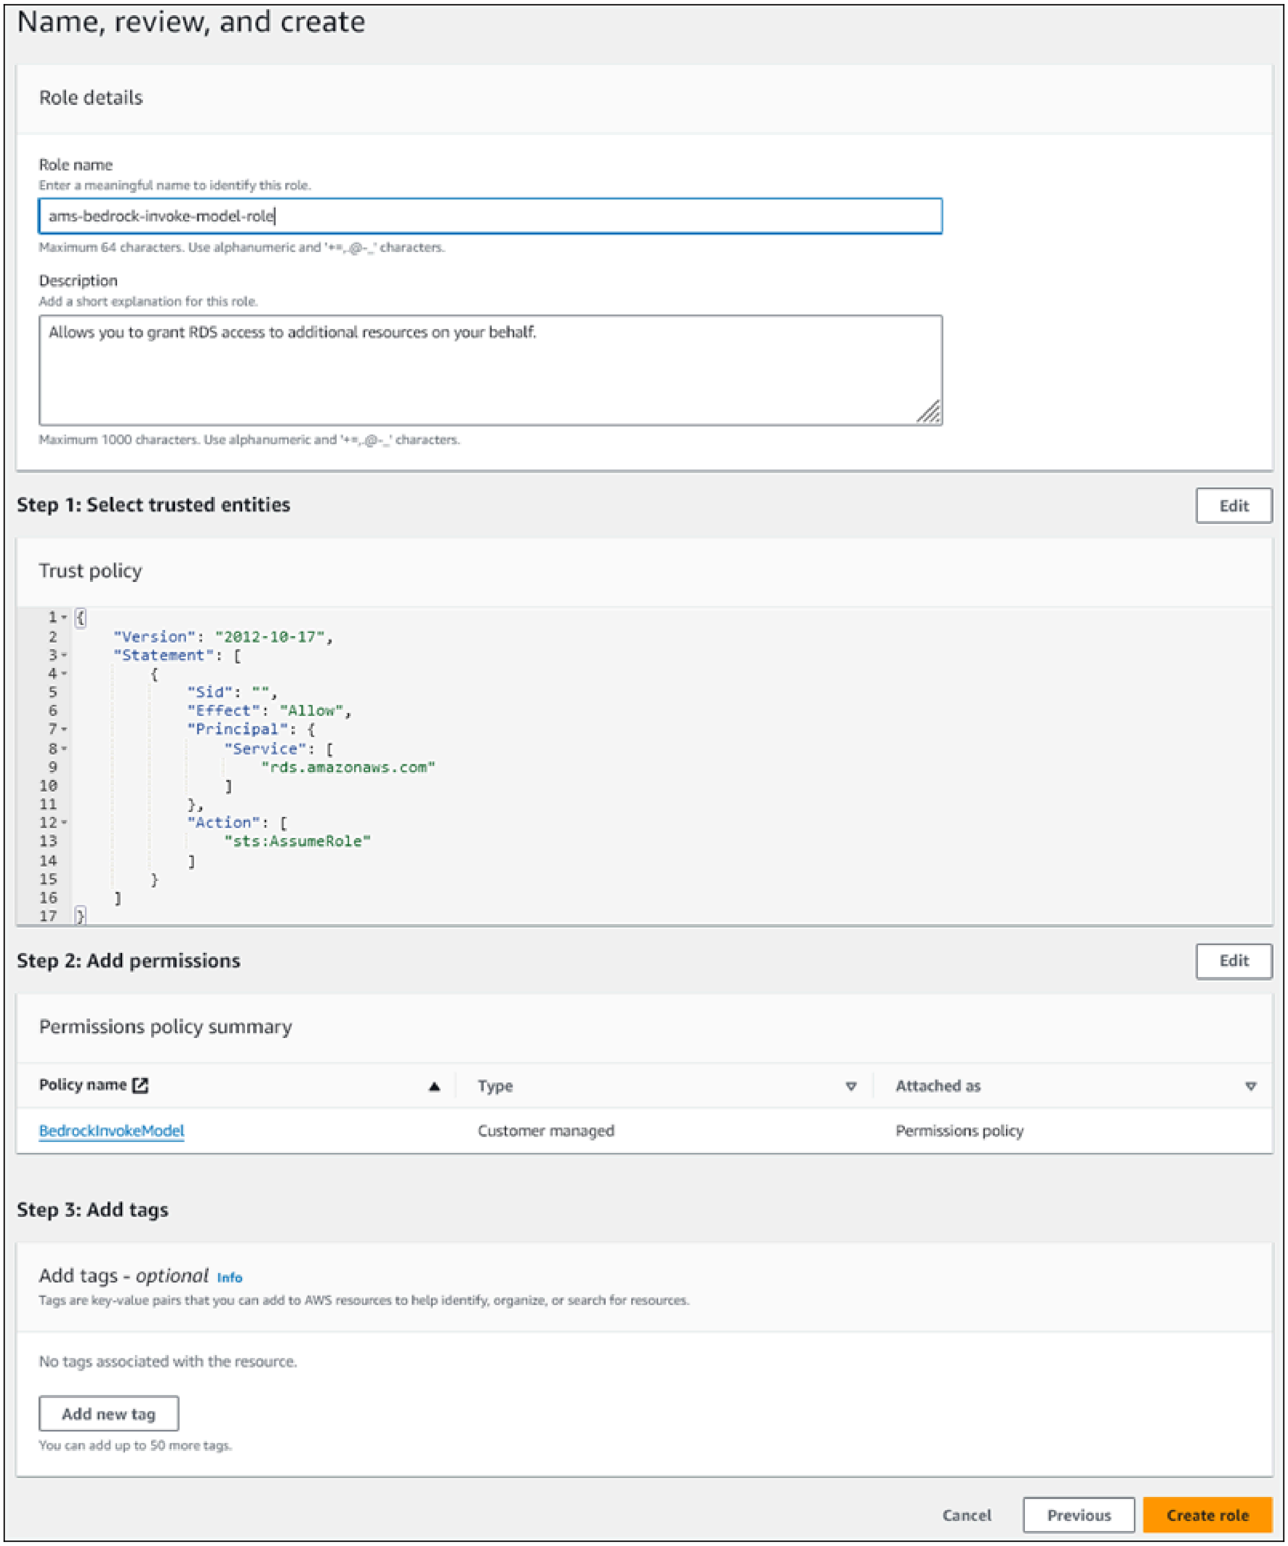
9. Review your policy, then choose **Create policy**.

Next you create the IAM role that uses the Amazon Bedrock permission policy.

To create the IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** in the navigation pane.
3. Choose **Create role**.
4. On the **Select trusted entity** page, for **Use case**, choose **RDS**.
5. Select **RDS - Add Role to Database**, then choose **Next**.
6. On the **Add permissions** page, for **Permissions policies**, select the IAM policy that you created, then choose **Next**.
7. On the **Name, review, and create** page, enter a name for your role, for example **`ams-bedrock-invoke-model-role`**.

   The role should resemble the following figure.



Name, review, and create

Role details

Role name
Enter a meaningful name to identify this role.
ams-bedrock-invoke-model-role
Maximum 64 characters. Use alphanumeric and '+=,.@-_' characters.

Description
Add a short explanation for this role.
Allows you to grant RDS access to additional resources on your behalf.
Maximum 1000 characters. Use alphanumeric and '+=,.@-_' characters.

Step 1: Select trusted entities

Trust policy

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": [
                "sts:AssumeRole"
            ]
        }
    ]
}
```

Step 2: Add permissions

Permissions policy summary

Policy name	Type	Attached as
BedrockInvokeModel	Customer managed	Permissions policy

Step 3: Add tags

Add tags - *optional* Info
Tags are key-value pairs that you can add to AWS resources to help identify, organize, or search for resources.

No tags associated with the resource.

You can add up to 50 more tags.

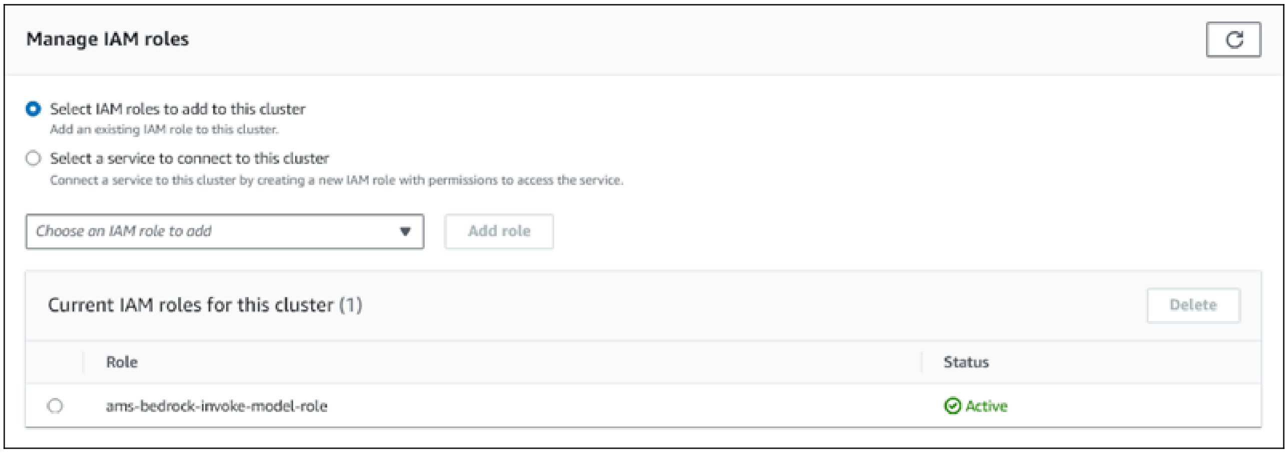
8. Review your role, then choose **Create role**.

Next you associate the Amazon Bedrock IAM role with your DB cluster.

To associate the IAM role with your DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Bedrock services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select IAM to add to this cluster**.
6. Choose the IAM that you created, and then choose **Add role**.

   The IAM role is associated with your DB cluster, first with the status **Pending**, then **Active**. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.



Manage IAM roles

● Select IAM roles to add to this cluster
Add an existing IAM role to this cluster.

○ Select a service to connect to this cluster
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

Choose an IAM role to add ▼ | Add role

Current IAM roles for this cluster (1) | Delete

	Role	Status
○	ams-bedrock-invoke-model-role	✓ Active

You must add the ARN of this IAM role to the `aws_default_bedrock_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see [Working with DB cluster parameter groups](#).

To configure the DB cluster parameter

1. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.
2. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.

3. Find the `aws_default_bedrock_role` parameter in your custom DB cluster parameter group.
4. In the **Value** field, enter the ARN of the IAM role.
5. Choose **Save changes** to save the setting.
6. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

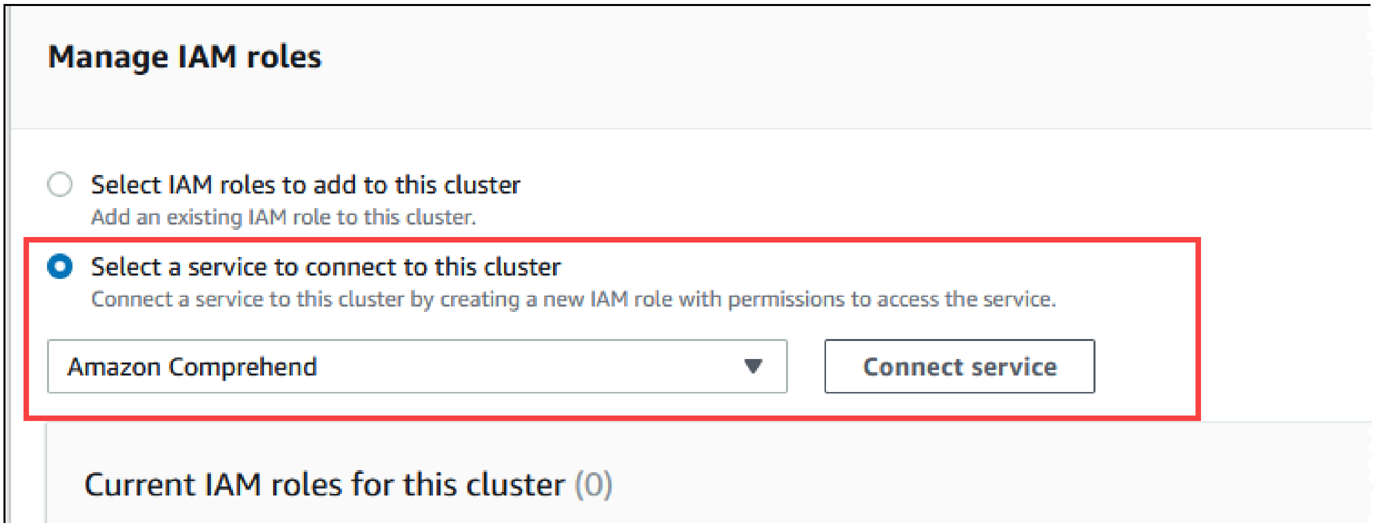
The IAM integration for Amazon Bedrock is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Bedrock by Granting database users access to Aurora machine learning.

Setting up your Aurora MySQL DB cluster to use Amazon Comprehend

Aurora machine learning relies on AWS Identity and Access Management roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Comprehend services. The following procedure automatically creates an IAM role and policy for your cluster so that it can use Amazon Comprehend.

To set up your Aurora MySQL DB cluster to use Amazon Comprehend

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Comprehend services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select a service to connect to this cluster**.
6. Choose **Amazon Comprehend** from the menu, and then choose **Connect service**.



Manage IAM roles

○ Select IAM roles to add to this cluster
Add an existing IAM role to this cluster.

● Select a service to connect to this cluster
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

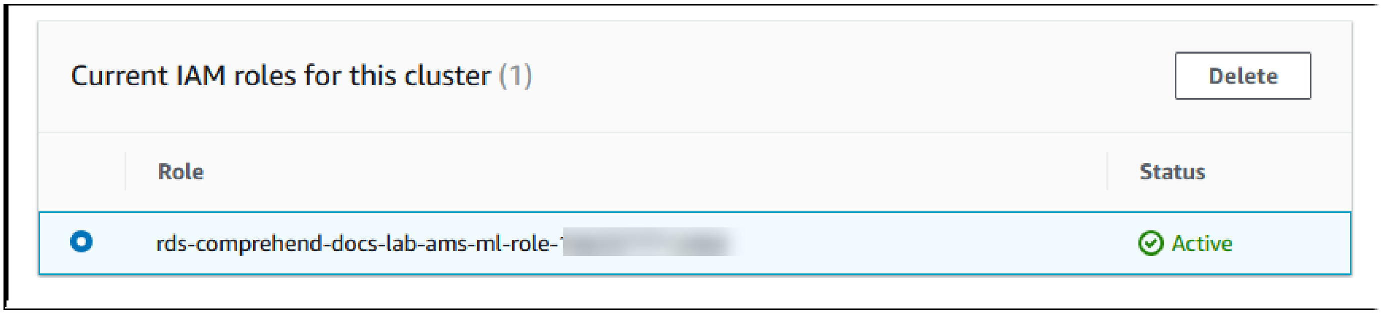
Amazon Comprehend ▼

Current IAM roles for this cluster (0)

7. The **Connect cluster to Amazon Comprehend** dialog doesn't require any additional information. However, you might see a message notifying you that the integration between Aurora and Amazon Comprehend is currently in preview. Be sure to read the message before you continue. You can choose **Cancel** if you prefer not to proceed.

8. Choose **Connect service** to complete the integration process.

   Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use Amazon Comprehend services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list as shown in the following image.



Current IAM roles for this cluster (1)

	Role	Status
●	rds-comprehend-docs-lab-ams-ml-role-[redacted]	✓ Active

   You need to add the ARN of this IAM role to the `aws_default_comprehend_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see Working with DB cluster parameter groups.

   After creating your custom DB cluster parameter group and associating it with your Aurora MySQL DB cluster, you can continue following these steps.

If your cluster uses a custom DB cluster parameter group, do as follows.

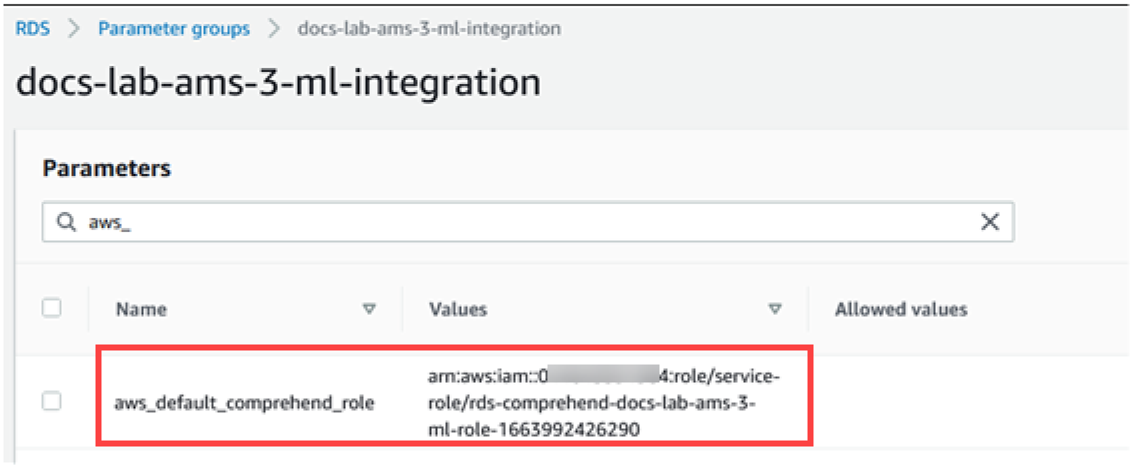
a. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.

b. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.

c. Find the `aws_default_comprehend_role` parameter in your custom DB cluster parameter group.

d. In the **Value** field, enter the ARN of the IAM role.

e. Choose **Save changes** to save the setting. In the following image, you can find an example.



RDS > Parameter groups > docs-lab-ams-3-ml-integration

docs-lab-ams-3-ml-integration

Parameters

aws_

□	Name	Values	Allowed values
□	aws_default_comprehend_role	arn:aws:iam::0[redacted]4:role/service-role/rds-comprehend-docs-lab-ams-3-ml-role-1663992426290	

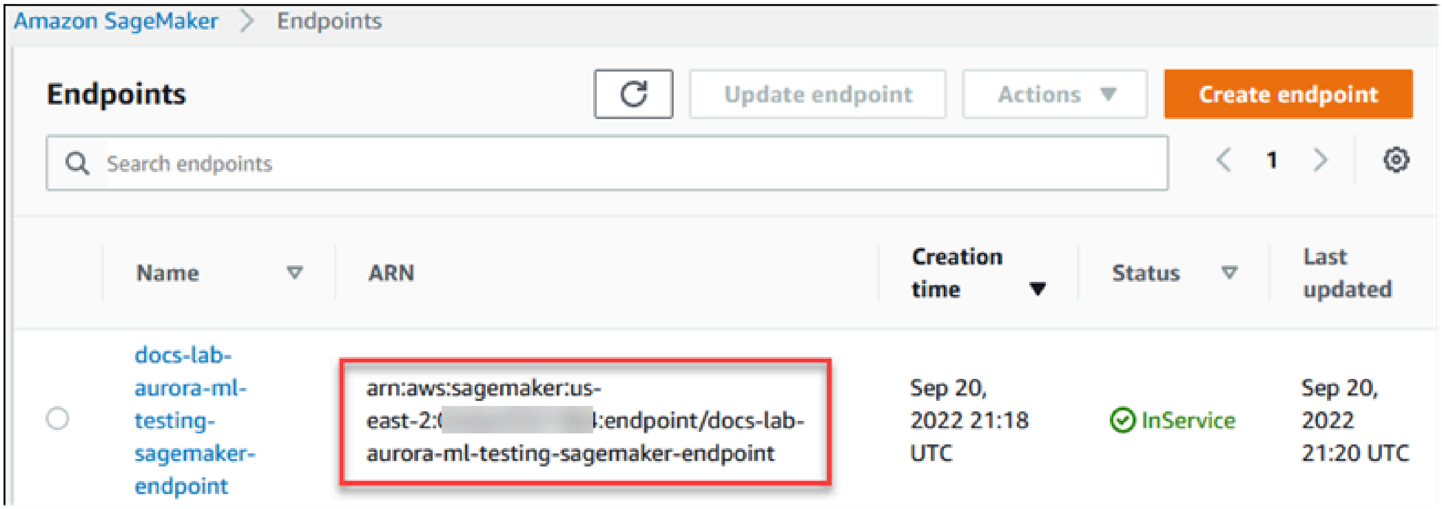
Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM integration for Amazon Comprehend is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Comprehend by granting access to the appropriate database users.

Setting up your Aurora MySQL DB cluster to use SageMaker

The following procedure automatically creates the IAM role and policy for your Aurora MySQL DB cluster so that it can use SageMaker. Before trying to follow this procedure, be sure that you have the SageMaker endpoint available so that you can enter it when needed. Typically, data scientists on your team would do the work to produce an endpoint that you can use from your Aurora MySQL

DB cluster. You can find such endpoints in the [SageMaker console](). In the navigation pane, open the **Inference** menu and choose **Endpoints**. In the following image, you can find an example.



Amazon SageMaker > Endpoints

Endpoints

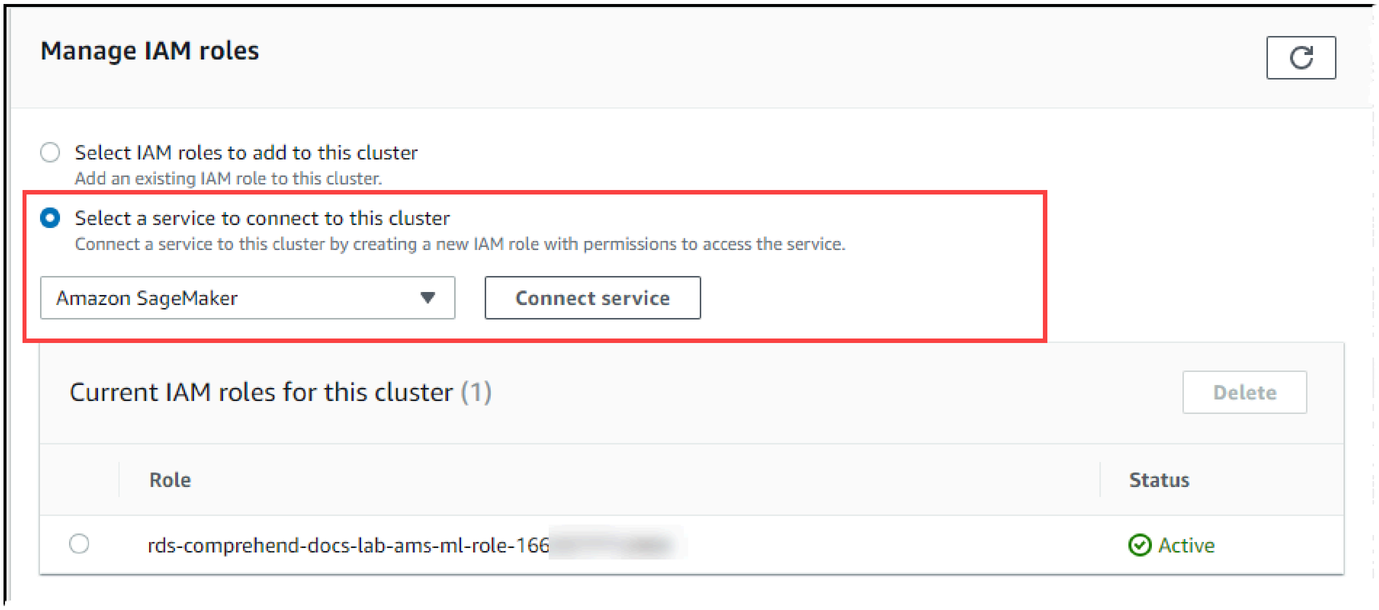
Update endpoint | Actions ▼ | Create endpoint

Search endpoints

	Name	ARN	Creation time	Status	Last updated
○	docs-lab-aurora-ml-testing-sagemaker-endpoint	arn:aws:sagemaker:us-east-2:[redacted]:endpoint/docs-lab-aurora-ml-testing-sagemaker-endpoint	Sep 20, 2022 21:18 UTC	✓ InService	Sep 20, 2022 21:20 UTC

To set up your Aurora MySQL DB cluster to use SageMaker

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/]().
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **SageMaker** from the selector.



Manage IAM roles

○ Select IAM roles to add to this cluster
Add an existing IAM role to this cluster.

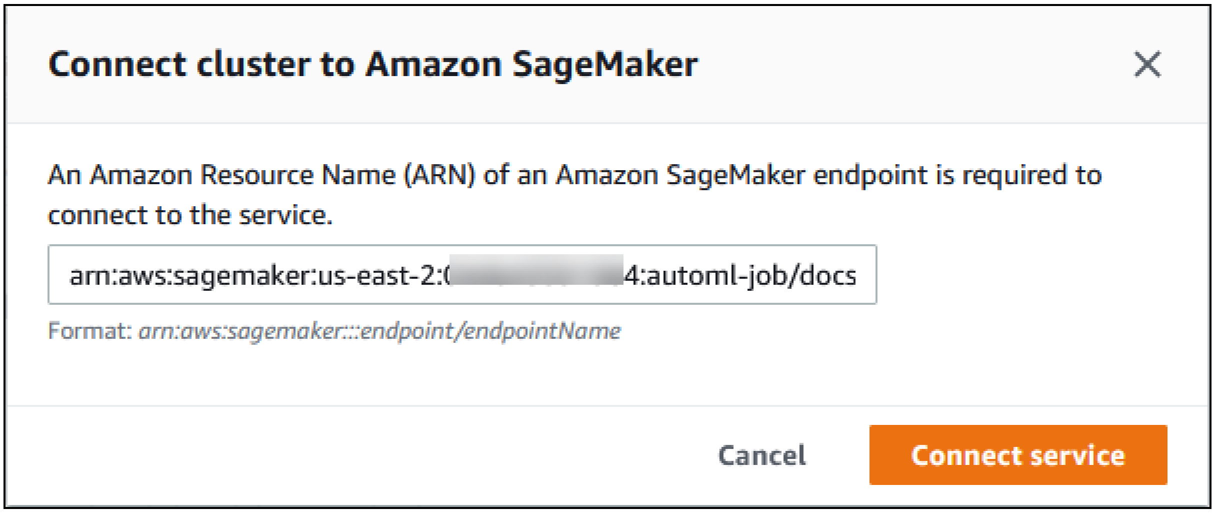
● Select a service to connect to this cluster
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

Amazon SageMaker ▼ | Connect service

Current IAM roles for this cluster (1) | Delete

	Role	Status
○	rds-comprehend-docs-lab-ams-ml-role-166[redacted]	✓ Active

5. Choose **Connect service**.
6. In the **Connect cluster to SageMaker** dialog, enter the ARN of the SageMaker endpoint.



Connect cluster to Amazon SageMaker

An Amazon Resource Name (ARN) of an Amazon SageMaker endpoint is required to connect to the service.

arn:aws:sagemaker:us-east-2:[redacted]4:automl-job/docs

Format: *arn:aws:sagemaker:::endpoint/endpointName*

7. Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use SageMaker services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.
8. Open the IAM console at https://console.aws.amazon.com/iam/.
9. Choose **Roles** from the Access management section of the AWS Identity and Access Management navigation menu.
10. Find the role from among those listed. Its name uses the following pattern.

```
rds-sagemaker-your-cluster-name-role-auto-generated-digits
```

11. Open the role's Summary page and locate the ARN. Note the ARN or copy it using the copy widget.
12. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
13. Choose your Aurora MySQL DB cluster, and then choose its **Configuration** tab.
14. Locate the DB cluster parameter group, and choose the link to open your custom DB cluster parameter group. Find the `aws_default_sagemaker_role` parameter and enter the ARN of the IAM role in the Value field and Save the setting.
15. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM setup is now complete. Continue setting up your Aurora MySQL DB cluster to work with SageMaker by granting access to the appropriate database users.

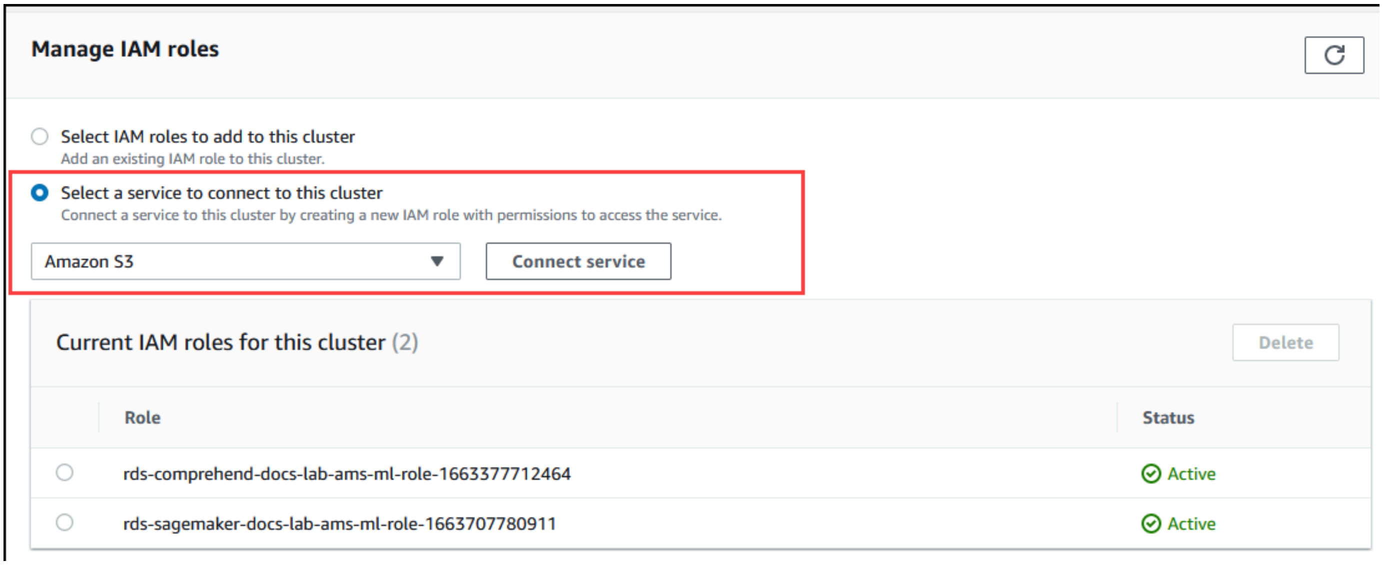
If you want to use your SageMaker models for training rather than using pre-built SageMaker components, you also need to add the Amazon S3 bucket to your Aurora MySQL DB cluster, as outlined in the Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional) that follows.

Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional)

To use SageMaker with your own models rather than using the pre-built components provided by SageMaker, you need to set up an Amazon S3 bucket for the Aurora MySQL DB cluster to use. For more information about creating an Amazon S3 bucket, see Creating a bucket in the *Amazon Simple Storage Service User Guide*.

To set up your Aurora MySQL DB cluster to use an Amazon S3 bucket for SageMaker

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **Amazon S3** from the selector.



Manage IAM roles

○ Select IAM roles to add to this cluster
Add an existing IAM role to this cluster.

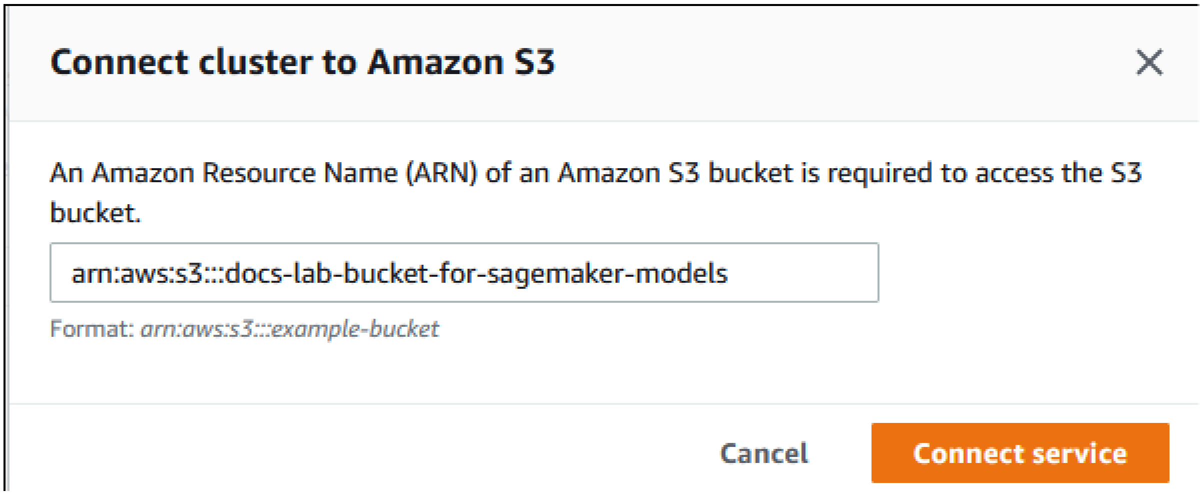
● Select a service to connect to this cluster
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

Amazon S3 ▼ | Connect service

Current IAM roles for this cluster (2) | Delete

	Role	Status
○	rds-comprehend-docs-lab-ams-ml-role-1663377712464	✓ Active
○	rds-sagemaker-docs-lab-ams-ml-role-1663707780911	✓ Active

5. Choose **Connect service**.
6. In the **Connect cluster to Amazon S3** dialog, enter the ARN of the Amazon S3 bucket, as shown in the following image.



Connect cluster to Amazon S3

An Amazon Resource Name (ARN) of an Amazon S3 bucket is required to access the S3 bucket.

arn:aws:s3:::docs-lab-bucket-for-sagemaker-models

Format: *arn:aws:s3:::example-bucket*

7. Choose **Connect service** to complete this process.

For more information about using Amazon S3 buckets with SageMaker, see Specify an Amazon S3 Bucket to Upload Training Datasets and Store Output Data in the *Amazon SageMaker Developer Guide*. To learn more about working with SageMaker, see Get Started with Amazon SageMaker Notebook Instancesin the in the *Amazon SageMaker Developer Guide*.

Granting database users access to Aurora machine learning

Database users must be granted permission to invoke Aurora machine learning functions. How you grant permission depends on the version of MySQL that you use for your Aurora MySQL DB cluster, as outlined in the following. How you do so depends on the version of MySQL that your Aurora MySQL DB cluster uses.

- For Aurora MySQL version 3 (MySQL 8.0 compatible), database users must be granted the appropriate *database role*. For more informations, see Using Roles in the *MySQL 8.0 Reference Manual*.
- For Aurora MySQL version 2 (MySQL 5.7 compatible), database users are granted *privileges*. For more information, see Access Control and Account Management in the *MySQL 5.7 Reference Manual*.

The following table shows the roles and privileges that database users need to work with machine learning functions.

Aurora MySQL version 3 (role)	Aurora MySQL version 2 (privilege)
AWS_BEDROCK_ACCESS	–
AWS_COMPREHEND_ACCESS	INVOKE COMPREHEND
AWS_SAGEMAKER_ACCESS	INVOKE SAGEMAKER

Granting access to Amazon Bedrock functions

To give database users access to Amazon Bedrock functions, use the following SQL statement:

```
GRANT AWS_BEDROCK_ACCESS TO user@domain-or-ip-address;
```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with Amazon Bedrock:

```
GRANT EXECUTE ON FUNCTION database_name.function_name TO user@domain-or-ip-address;
```

Finally, database users must have their roles set to AWS_BEDROCK_ACCESS:

```
SET ROLE AWS_BEDROCK_ACCESS;
```

The Amazon Bedrock functions are now available for use.

Granting access to Amazon Comprehend functions

To give database users access to Amazon Comprehend functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

  ```
  GRANT AWS_COMPREHEND_ACCESS TO user@domain-or-ip-address;
  ```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

  ```
  GRANT INVOKE COMPREHEND ON *.* TO user@domain-or-ip-address;
  ```

The Amazon Comprehend functions are now available for use. For usage examples, see Using Amazon Comprehend with your Aurora MySQL DB cluster.

Granting access to SageMaker functions

To give database users access to SageMaker functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

  ```
  GRANT AWS_SAGEMAKER_ACCESS TO user@domain-or-ip-address;
  ```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

  ```
  GRANT INVOKE SAGEMAKER ON *.* TO user@domain-or-ip-address;
  ```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with SageMaker. Suppose that you created two functions, db1.anomoly_score and db2.company_forecasts, to invoke the services of your SageMaker endpoint. You grant execute privileges as shown in the following example.

```
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1;
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2;
```

The SageMaker functions are now available for use. For usage examples, see Using SageMaker with your Aurora MySQL DB cluster.

Using Amazon Bedrock with your Aurora MySQL DB cluster

To use Amazon Bedrock, you create a user-defined function (UDF) in your Aurora MySQL database that invokes a model. For more information, see Supported models in Amazon Bedrock in the *Amazon Bedrock User Guide*.

A UDF uses the following syntax:

```
CREATE FUNCTION function_name (argument type)
        [DEFINER = user]
    RETURNS mysql_data_type
    [SQL SECURITY {DEFINER | INVOKER}]
    ALIAS AWS_BEDROCK_INVOKE_MODEL
```

```
    MODEL ID 'model_id'
    [CONTENT_TYPE 'content_type']
    [ACCEPT 'content_type']
    [TIMEOUT_MS timeout_in_milliseconds];
```

- Amazon Bedrock functions don't support `RETURNS JSON`. You can use `CONVERT` or `CAST` to convert from `TEXT` to `JSON` if needed.
- If you don't specify `CONTENT_TYPE` or `ACCEPT`, the default is `application/json`.
- If you don't specify `TIMEOUT_MS`, the value for `aurora_ml_inference_timeout` is used.

For example, the following UDF invokes the Amazon Titan Text Express model:

```
CREATE FUNCTION invoke_titan (request_body TEXT)
    RETURNS TEXT
    ALIAS AWS_BEDROCK_INVOKE_MODEL
    MODEL ID 'amazon.titan-text-express-v1'
    CONTENT_TYPE 'application/json'
    ACCEPT 'application/json';
```

To allow a DB user to use this function, use the following SQL command:

```
GRANT EXECUTE ON FUNCTION database_name.invoke_titan TO user@domain-or-ip-address;
```

Then the user can call `invoke_titan` like any other function, as shown in the following example. Make sure to format the request body according to the Amazon Titan text models.

```
CREATE TABLE prompts (request varchar(1024));
INSERT INTO prompts VALUES (
'{
    "inputText": "Generate synthetic data for daily product sales in various categories
 - include row number, product name, category, date of sale and price. Produce output
 in JSON format. Count records and ensure there are no more than 5.",
    "textGenerationConfig": {
        "maxTokenCount": 1024,
        "stopSequences": [],
        "temperature":0,
        "topP":1
    }
}');
```

~~~
SELECT invoke_titan(request) FROM prompts;

{"inputTextTokenCount":44,"results":[{"tokenCount":296,"outputText":"
```tabular-data-json
{
    "rows": [
        {
            "Row Number": "1",
            "Product Name": "T-Shirt",
            "Category": "Clothing",
            "Date of Sale": "2024-01-01",
            "Price": "$20"
        },
        {
            "Row Number": "2",
            "Product Name": "Jeans",
            "Category": "Clothing",
            "Date of Sale": "2024-01-02",
            "Price": "$30"
        },
        {
            "Row Number": "3",
            "Product Name": "Hat",
            "Category": "Accessories",
            "Date of Sale": "2024-01-03",
            "Price": "$15"
        },
        {
            "Row Number": "4",
            "Product Name": "Watch",
            "Category": "Accessories",
            "Date of Sale": "2024-01-04",
            "Price": "$40"
        },
        {
            "Row Number": "5",
            "Product Name": "Phone Case",
            "Category": "Accessories",
            "Date of Sale": "2024-01-05",
            "Price": "$25"
        }
    ]
}
~~~

~~~
```","completionReason":"FINISH"}]}
~~~

For other models that you use, make sure to format the request body appropriately for them. For more information, see Inference parameters for foundation models in the *Amazon Bedrock User Guide*.

Using Amazon Comprehend with your Aurora MySQL DB cluster

For Aurora MySQL, Aurora machine learning provides the following two built-in functions for working with Amazon Comprehend and your text data. You provide the text to analyze (`input_data`) and specify the language (`language_code`).

aws_comprehend_detect_sentiment

This function identifies the text as having a positive, negative, neutral, or mixed emotional posture. This function's reference documentation is as follows.

```
aws_comprehend_detect_sentiment(
  input_text,
  language_code
  [,max_batch_size]
)
```

To learn more, see Sentiment in the *Amazon Comprehend Developer Guide*.

aws_comprehend_detect_sentiment_confidence

This function measures the confidence level of the sentiment detected for a given text. It returns a value (type, `double`) that indicates the confidence of the sentiment assigned by the aws_comprehend_detect_sentiment function to the text. Confidence is a statistical metric between 0 and 1. The higher the confidence level, the more weight you can give the result. A summary of the function's documentation is as follows.

```
aws_comprehend_detect_sentiment_confidence(
  input_text,
  language_code
  [,max_batch_size]
)
```

In both functions (aws_comprehend_detect_sentiment_confidence, aws_comprehend_detect_sentiment) the `max_batch_size` uses a default value of 25 if none is specified. Batch size should always be greater than 0. You can use `max_batch_size` to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora MySQL DB cluster. For more information, see Performance considerations for using Aurora machine learning with Aurora MySQL.

For more information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see DetectSentiment

Example Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes these two functions to see how happy your customers are with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies both built-in functions to the text in the `feedback` column of the table and outputs the results. The confidence values returned by the function are doubles between 0.0 and 1.0. For more readable output, this query rounds the results to 6 decimal points. For easier comparisons, this query also sorts the results in descending order, from the result having the highest degree of confidence, first.

```
SELECT feedback AS 'Customer feedback',
    aws_comprehend_detect_sentiment(feedback, 'en') AS Sentiment,
    ROUND(aws_comprehend_detect_sentiment_confidence(feedback, 'en'), 6)
    AS Confidence FROM support
    ORDER BY Confidence DESC;
+---------------------------------------------------------+-----------+------------+
| Customer feedback                                       | Sentiment | Confidence |
+---------------------------------------------------------+-----------+------------+
| Thank you for the excellent customer support!           | POSITIVE  |   0.999771 |
| The latest version of this product stinks!              | NEGATIVE  |   0.999184 |
| Your support team is just awesome! I am blown away.     | POSITIVE  |   0.997774 |
| Your product is too complex, but your support is great. | MIXED     |   0.957958 |
| Your support tech helped me in fifteen minutes.         | POSITIVE  |   0.949491 |
| My problem was never resolved!                          | NEGATIVE  |   0.920644 |
| When will the new version of this product be released?  | NEUTRAL   |   0.902706 |
| I cannot stand that chatbot.                            | NEGATIVE  |   0.895219 |
| Your support tech talked down to me.                    | NEGATIVE  |   0.868598 |
| It took me way too long to get a real person.           | NEGATIVE  |   0.481805 |
+---------------------------------------------------------+-----------+------------+
 10 rows in set (0.1898 sec)
```

Example Example: Determining the average sentiment for text above a specific confidence level

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')
  WHEN 'POSITIVE' THEN 1.0
  WHEN 'NEGATIVE' THEN -1.0
  ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total
FROM productTable
WHERE productTable.productCode = 1302 AND
    aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

Using SageMaker with your Aurora MySQL DB cluster

To use SageMaker functionality from your Aurora MySQL DB cluster, you need to create stored functions that embed your calls to the SageMaker endpoint and its inference features. You do so by using MySQL's `CREATE FUNCTION` in generally the same way that you do for other processing tasks on your Aurora MySQL DB cluster.

To use models deployed in SageMaker for inference, you create user-defined functions using MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker endpoint after applying the model to the input parameters.

All Aurora machine learning stored functions return numeric types or `VARCHAR`. You can use any numeric type except `BIT`. Other types, such as `JSON`, `BLOB`, `TEXT`, and `DATE` aren't allowed.

The following example shows the `CREATE FUNCTION` syntax for working with SageMaker.

```
CREATE FUNCTION function_name (
     arg1 type1,
     arg2 type2, ...)
     [DEFINER = user]
  RETURNS mysql_type
  [SQL SECURITY { DEFINER | INVOKER } ]
  ALIAS AWS_SAGEMAKER_INVOKE_ENDPOINT
  ENDPOINT NAME 'endpoint_name'
  [MAX_BATCH_SIZE max_batch_size];
```

This is an extension of the regular CREATE FUNCTION DDL statement. In the CREATE FUNCTION statement that defines the SageMaker function, you don't specify a function body. Instead, you specify the keyword ALIAS where the function body usually goes. Currently, Aurora machine learning only supports aws_sagemaker_invoke_endpoint for this extended syntax. You must specify the endpoint_name parameter. An SageMaker endpoint can have different characteristics for each model.

> **Note**
>
> For more information about CREATE FUNCTION, see CREATE PROCEDURE and CREATE FUNCTION Statements in the MySQL 8.0 Reference Manual.

The max_batch_size parameter is optional. By default, maximum batch size is 10,000. You can use this parameter in your function to restrict the maximum number of inputs processed in a batched request to SageMaker. The max_batch_size parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker return a response more quickly. This parameter affects the size of an internal buffer used for SageMaker request processing. Specifying too large a value for max_batch_size might cause substantial memory overhead on your DB instance.

We recommend that you leave the MANIFEST setting at its default value of OFF. Although you can use the MANIFEST ON option, some SageMaker features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker.

You create a separate stored function for each of your SageMaker models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the AWS services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the NOT DETERMINISTIC property. If you don't specify that property explicitly, Aurora sets NOT DETERMINISTIC automatically. This requirement is because the SageMaker model can be changed without any notification to the database. If that happens, calls to an Aurora machine learning function might return different results for the same input within a single transaction.

You can't use the characteristics CONTAINS SQL, NO SQL, READS SQL DATA, or MODIFIES SQL DATA in your CREATE FUNCTION statement.

Following is an example usage of invoking an SageMaker endpoint to detect anomalies. There is an SageMaker endpoint random-cut-forest-model. The corresponding model is already trained by the random-cut-forest algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```
CREATE FUNCTION anomaly_score(value real) returns real
  alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value))
 from nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
  where anomaly_detection(value) > @score_cutoff;
```

Character set requirement for SageMaker functions that return strings

We recommend specifying a character set of utf8mb4 as the return type for your SageMaker functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the utf8mb4 character set. The following example shows how to declare the utf8mb4 character set for your function.

```
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...
```

Currently, each SageMaker function that returns a string uses the character set utf8mb4 for the return value. The return value uses this character set even if your SageMaker function declares a different character set for its return type implicitly or explicitly. If your SageMaker function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a DISTINCT clause creates a temporary table. Thus, the SageMaker function result might be truncated due to the way strings are handled internally during a query.

Exporting data to Amazon S3 for SageMaker model training (Advanced)

We recommend that you get started with Aurora machine learning and SageMaker by using some of the provided algorithms, and that the data scientists on your team provide you with the SageMaker endpoints that you can use with your SQL code. In the following, you can find minimal information about using your own Amazon S3 bucket with your your own SageMaker models and your Aurora MySQL DB cluster.

Machine learning consists of two major steps: training, and inference. To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE S3` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format `TEXT` is the same as the existing MySQL export format. This is the default format.
- Format `CSV` is a newly introduced format that follows the specification in RFC-4180.
- If you specify the optional keyword `HEADER`, the output file contains one header line. The labels in the header line correspond to the column names from the `SELECT` statement.
- You can still use the keywords `CSV` and `HEADER` as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[FORMAT {CSV|TEXT} [HEADER]]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
```

Performance considerations for using Aurora machine learning with Aurora MySQL

The Amazon Bedrock, Amazon Comprehend, and SageMaker services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora MySQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning.

Model and prompt

Performance when using Amazon Bedrock is highly dependent on the model and prompt that you use. Choose a model and prompt that are optimal for your use case.

Query cache

The Aurora MySQL query cache doesn't work for Aurora machine learning functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call Aurora machine learning functions.

Batch optimization for Aurora machine learning function calls

The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker endpoint, you define the batch size parameter. This parameter influences how many rows are transferred for every underlying call to SageMaker. For queries that process large numbers of rows, the overhead to make a separate SageMaker call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker function, you can tell by checking the query plan produced by the `EXPLAIN PLAN` statement. In this case, the `extra` column in the execution plan includes `Batched machine learning`. The following example shows a call to an SageMaker function that uses batch mode.

```
mysql> CREATE FUNCTION anomaly_score(val real) returns real alias
 aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)

mysql> explain select timestamp, value, anomaly_score(value) from nyc_taxi;
+----+-------------+----------+------------+------+---------------+------+---------
+------+------+----------+--------------------------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len |
 ref  | rows | filtered | Extra                    |
+----+-------------+----------+------------+------+---------------+------+---------
+------+------+----------+--------------------------+
|  1 | SIMPLE      | nyc_taxi | NULL       | ALL  | NULL          | NULL | NULL    |
 NULL |   48 |   100.00 | Batched machine learning |
+----+-------------+----------+------------+------+---------------+------+---------
+------+------+----------+--------------------------+
1 row in set, 1 warning (0.01 sec)
```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional `max_batch_size` parameter. his parameter restricts the maximum number of `input_text` values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a `LIMIT` clause. By using a small value for `max_batch_size`, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

- Function calls within the select list or the `WHERE` clause of `SELECT` statements
- Function calls in the `VALUES` list of `INSERT` and `REPLACE` statements
- SageMaker functions in `SET` values in `UPDATE` statements:

```
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
  (ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
  (ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

Monitoring Aurora machine learning

You can monitor Aurora machine learning batch operations by querying several global variables, as shown in the following example.

```
show status like 'Aurora_ml%';
```

You can reset the status variables by using a `FLUSH STATUS` statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

`Aurora_ml_logical_request_cnt`

The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than `Aurora_ml_actual_request_cnt`.

`Aurora_ml_logical_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_actual_request_cnt`

The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_actual_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_cache_hit_cnt`

The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_retry_request_cnt`

The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset.

`Aurora_ml_single_request_cnt`

The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see Monitor Amazon SageMaker.

Using Amazon Aurora machine learning with Aurora PostgreSQL

By using Amazon Aurora machine learning with your Aurora PostgreSQL DB cluster, you can use Amazon Comprehend or Amazon SageMaker or Amazon Bedrock, depending on your needs. These services each support specific machine learning use cases.

Aurora machine learning is supported in certain AWS Regions and for specific versions of Aurora PostgreSQL only. Before trying to set up Aurora machine learning, check availability for your Aurora PostgreSQL version and your Region. For details, see Aurora machine learning with Aurora PostgreSQL.

Topics

Requirements for using Aurora machine learning with Aurora PostgreSQL

AWS machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Comprehend, SageMaker, and Amazon Bedrock. Before trying to set up your Aurora PostgreSQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The Amazon Comprehend, SageMaker, and Amazon Bedrock services must be running in the same AWS Region as your Aurora PostgreSQL DB cluster. You can't use Amazon Comprehend or SageMaker or Amazon Bedrock services from an Aurora PostgreSQL DB cluster in a different Region.
- If your Aurora PostgreSQL DB cluster is in a different virtual public cloud (VPC) based on the Amazon VPC service than your Amazon Comprehend and SageMaker services, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services.
- For SageMaker, the machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora PostgreSQL DB cluster, you need to have the Amazon Resource Name (ARN) of the SageMaker endpoint available. The data scientists on your team are likely best able to handle working with SageMaker to prepare the models and handle the other such tasks. To get started with Amazon SageMaker, see Get Started with Amazon SageMaker. For more information about inferences and endpoints, see Real-time inference.
- For Amazon Bedrock, you need to have the model ID of the Bedrock models that you want to use for inferences available during the configuration process of your Aurora PostgreSQL DB cluster. The data scientists on your team are likely best able to work with Bedrock to decide which models to use, fine tune them if needed and handle other such tasks. To get started with Amazon Bedrock, see How to setup Bedrock.
- Amazon Bedrock users need to request access to models before they are available for use. If you want to add additional models for text, chat, and image generation, you need to request access to models in Amazon Bedrock. For more information, see Model access.

Supported features and limitations of Aurora machine learning with Aurora PostgreSQL

Aurora machine learning supports any SageMaker endpoint that can read and write the comma-separated value (CSV) format through a `ContentType` value of `text/csv`. The built-in SageMaker algorithms that currently accept this format are the following.

- Linear Learner
- Random Cut Forest
- XGBoost

  To learn more about these algorithms, see Choose an Algorithm in the *Amazon SageMaker Developer Guide*.

When using Amazon Bedrock with Aurora machine learning, the following limitations apply:

- The user-defined functions (UDFs) provide a native way to interact with Amazon Bedrock. The UDFs don't have specific request or response requirements, so they can use any model.
- You can use UDFs to build any work flow desired. For example, you can combine base primitives such as `pg_cron` to run a query, fetch data, generate inferences, and write to tables to serve queries directly.
- UDFs don't support batched or parallel calls.
- The Aurora Machine Learning extension doesn't support vector interfaces. As part of the extension, a function is available to output the embeddings of model’s response in the `float8[]` format to store those embeddings in Aurora. For more information on the usage of `float8[]`, see Using Amazon Bedrock with your Aurora PostgreSQL DB cluster.

Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning

For Aurora machine learning to work with your Aurora PostgreSQL DB cluster, you need to create an AWS Identity and Access Management (IAM) role for each of the services that you want to use. The IAM role allows your Aurora PostgreSQL DB cluster to use the Aurora machine learning service on the cluster's behalf. You also need to install the Aurora machine learning extension. In the following topics, you can find setup procedures for each of these Aurora machine learning services.

Topics

Setting up Aurora PostgreSQL to use Amazon Bedrock

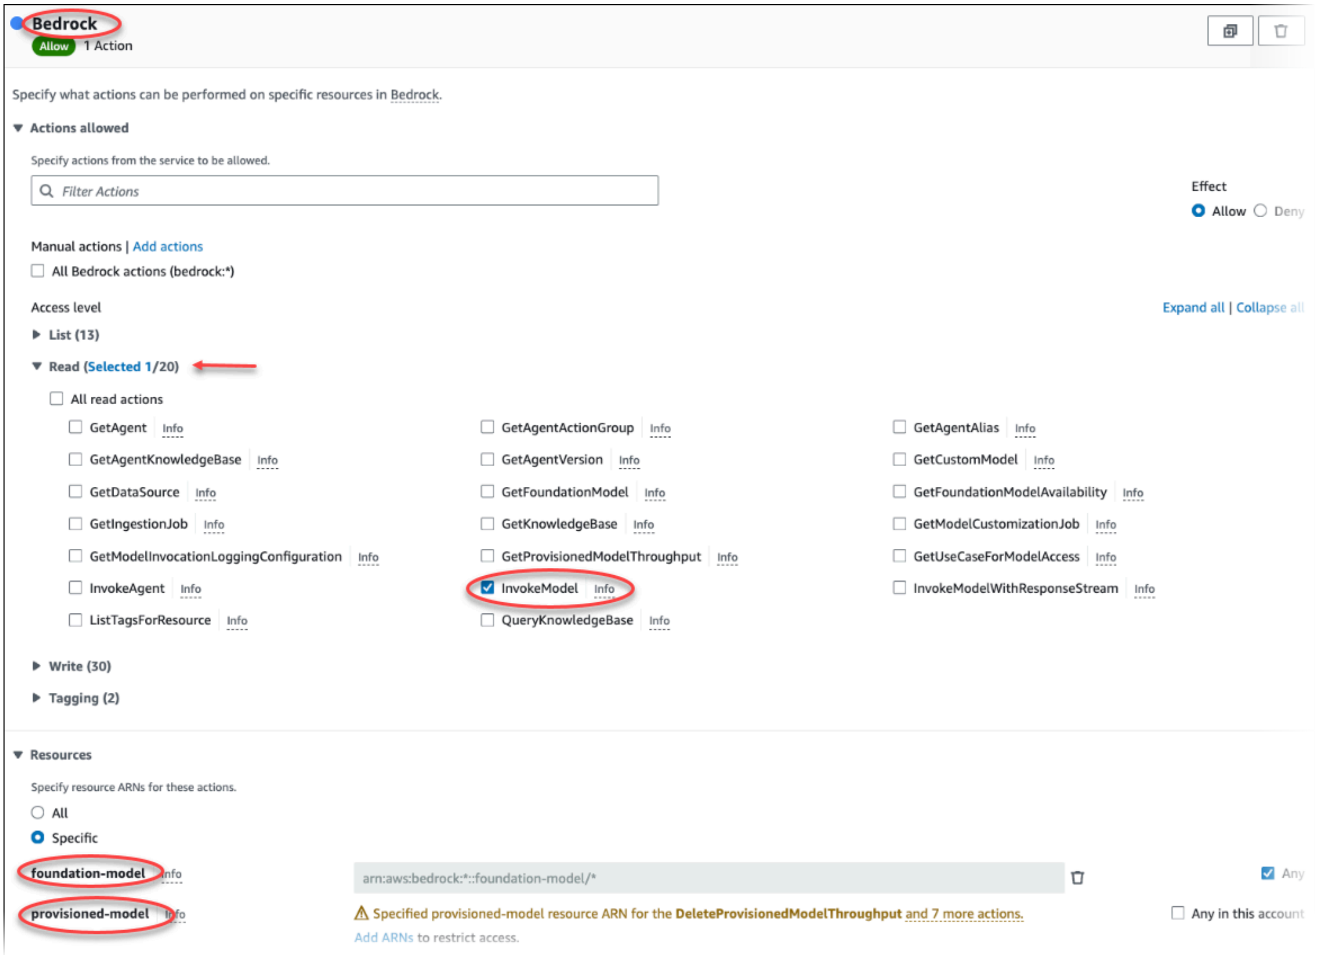
In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Bedrock on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Bedrock. For simplicity's sake, this procedure uses the AWS Management Console to complete all tasks.

To set up your Aurora PostgreSQL DB cluster to use Amazon Bedrock

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Open the IAM console at https://console.aws.amazon.com/iam/.
3. Choose **Policies** (under Access management) on the AWS Identity and Access Management (IAM) Console menu.

   a. Choose **Create policy**. In the Visual editor page, choose **Service** and then enter **Bedrock** in the Select a service field. Expand the Read access level. Choose **InvokeModel** from the Amazon Bedrock read settings.

   b. Choose the Foundation/Provisioned model you want to grant read access via the policy.



Bedrock

Allow 1 Action

Specify what actions can be performed on specific resources in Bedrock.

Bedrock	Limited: Read	region| string like |All	None

Add tags - *optional*

Tags are key-value pairs that you can add to AWS resources to help identify, organize, or search for resources.

No tags associated with the resource.

You can add up to 50 more tags.

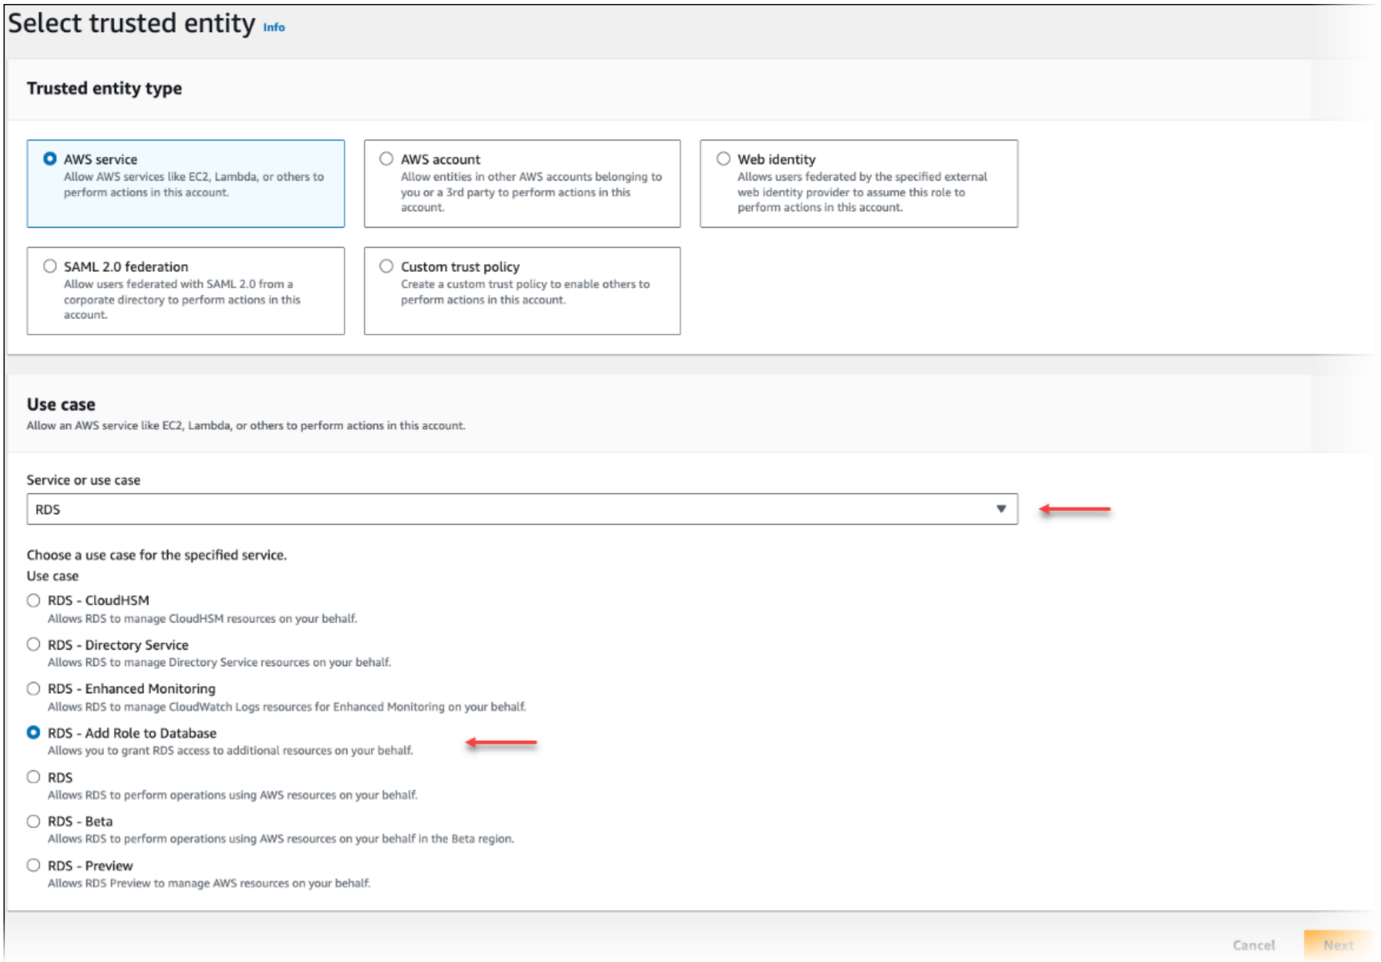
5. Choose **Create policy**. The Console displays an alert when the policy has been saved. You can find it in the list of Policies.

6. Choose **Roles** (under Access management) on the IAM Console.

7. Choose **Create role**.

8. On the Select trusted entity page, choose the **AWS service** tile, and then choose **RDS** to open the selector.

9. Choose **RDS – Add Role to Database**.



Select trusted entity Info

Trusted entity type

● AWS service
Allow AWS services like EC2, Lambda, or others to perform actions in this account.

○ AWS account
Allow entities in other AWS accounts belonging to you or a 3rd party to perform actions in this account.

○ Web identity
Allows users federated by the specified external web identity provider to assume this role to perform actions in this account.

○ SAML 2.0 federation
Allow users federated with SAML 2.0 from a corporate directory to perform actions in this account.

○ Custom trust policy
Create a custom trust policy to enable others to perform actions in this account.

Use case
Allow an AWS service like EC2, Lambda, or others to perform actions in this account.

Service or use case
RDS

Choose a use case for the specified service.
Use case

○ RDS - CloudHSM
Allows RDS to manage CloudHSM resources on your behalf.

○ RDS - Directory Service
Allows RDS to manage Directory Service resources on your behalf.

○ RDS - Enhanced Monitoring
Allows RDS to manage CloudWatch Logs resources for Enhanced Monitoring on your behalf.

● RDS - Add Role to Database
Allows you to grant RDS access to additional resources on your behalf.

○ RDS
Allows RDS to perform operations using AWS resources on your behalf.

○ RDS - Beta
Allows RDS to perform operations using AWS resources on your behalf in the Beta region.

○ RDS - Preview
Allows RDS Preview to manage AWS resources on your behalf.

10. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**.

11. **Next: Review**. Enter a name for the IAM role and a description.

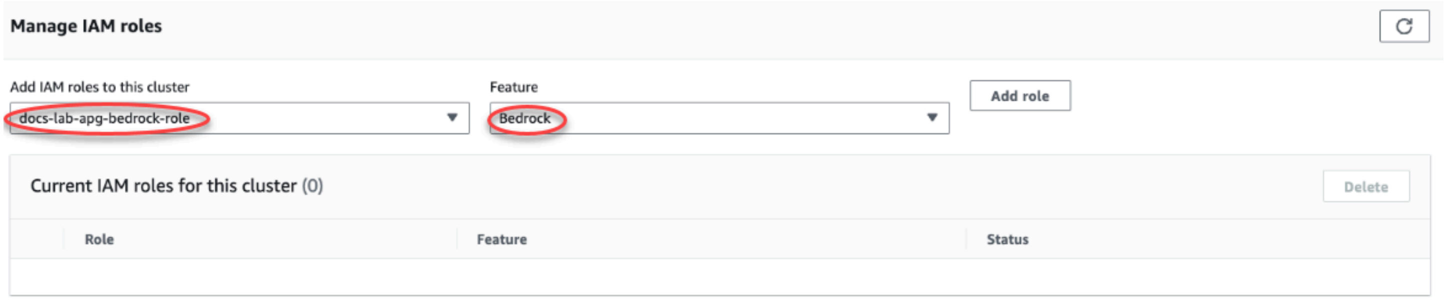
12. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

13. Navigate to the AWS Region where your Aurora PostgreSQL DB cluster is located.

14. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Bedrock.

15. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Bedrock, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.



Manage IAM roles

Add IAM roles to this cluster: docs-lab-apg-bedrock-role

Feature: Bedrock

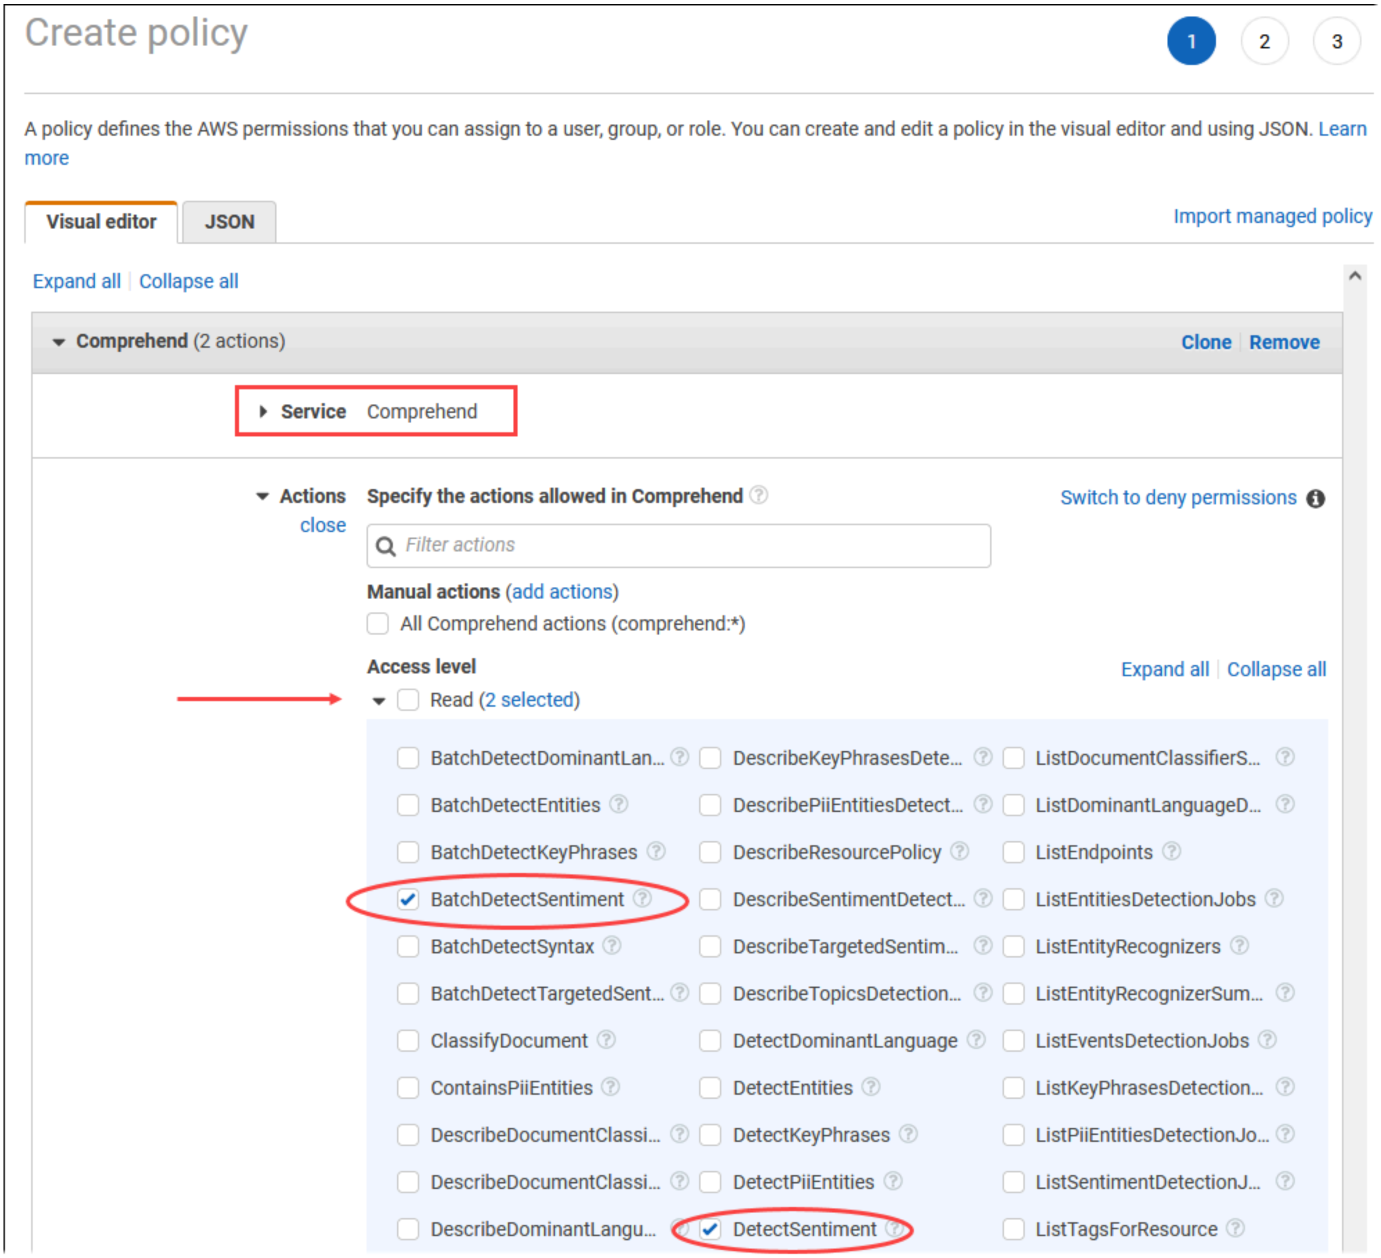
The IAM setup for Amazon Bedrock is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in [Installing the Aurora machine learning extension](#)

Setting up Aurora PostgreSQL to use Amazon Comprehend

In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Comprehend on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Comprehend For simplicity's sake, this procedure uses the AWS Management Console to complete all tasks.

To set up your Aurora PostgreSQL DB cluster to use Amazon Comprehend

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Open the IAM console at https://console.aws.amazon.com/iam/.
3. Choose **Policies** (under Access management) on the AWS Identity and Access Management (IAM) Console menu.



Create policy

1 2 3

A policy defines the AWS permissions that you can assign to a user, group, or role. You can create and edit a policy in the visual editor and using JSON. Learn more

The IAM setup for Amazon Comprehend is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension

Setting up Aurora PostgreSQL to use Amazon SageMaker

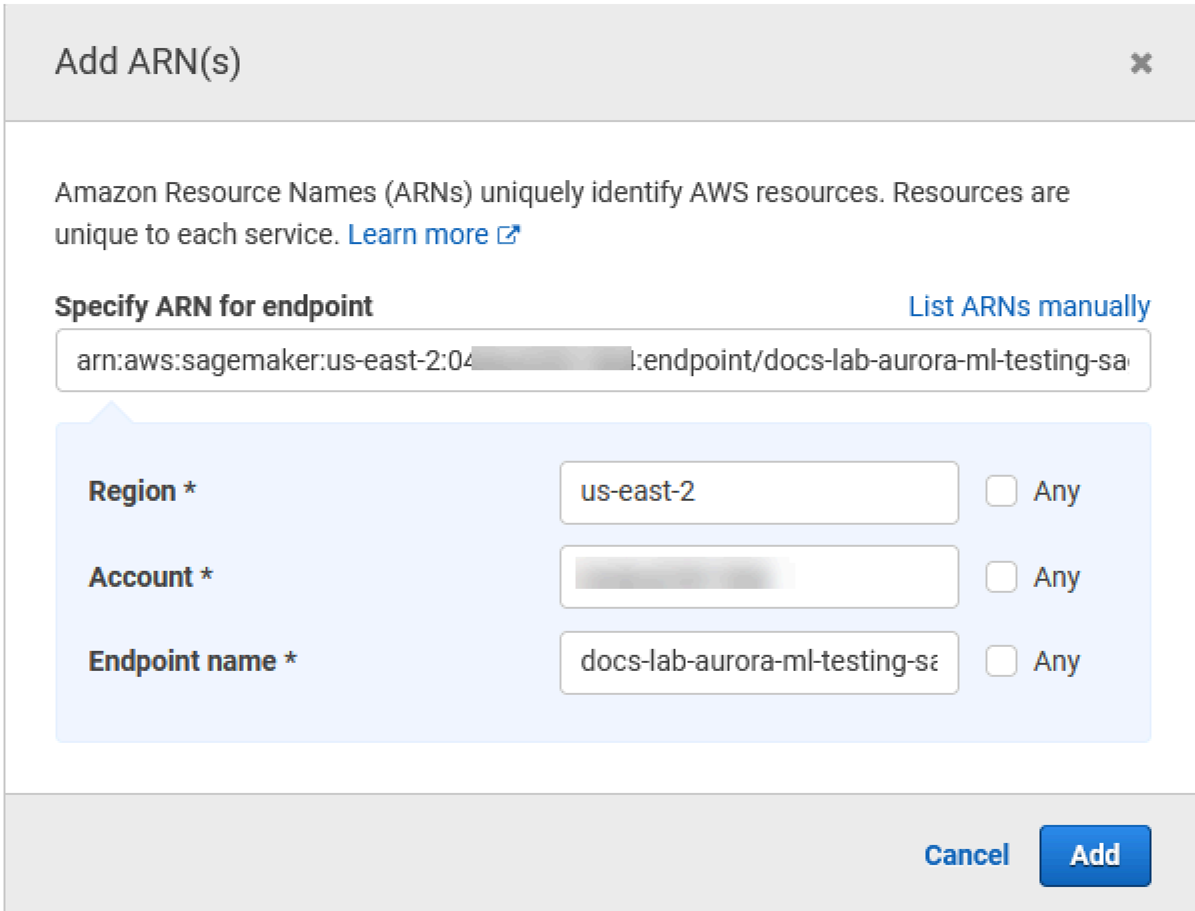
Before you can create the IAM policy and role for your Aurora PostgreSQL DB cluster, you need to have your SageMaker model setup and your endpoint available.

To set up your Aurora PostgreSQL DB cluster to use SageMaker

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Policies** (under Access management) on the AWS Identity and Access Management (IAM) Console menu, and then choose **Create policy**. In the Visual editor, choose **SageMaker** for the Service. For Actions, open the Read selector (under Access level) and choose **InvokeEndpoint**. When you this, a warning icon displays.

3. Open the Resources selector and choose the **Add ARN to restrict access** link under the Specify endpoint resource ARN for the InvokeEndpoint action.

4. Enter the AWS Region of your SageMaker resources and the name of your endpoint. Your AWS account is prefilled.



Amazon Resource Names (ARNs) uniquely identify AWS resources. Resources are unique to each service. Learn more

Specify ARN for endpoint — List ARNs manually

arn:aws:sagemaker:us-east-2:04[redacted]:endpoint/docs-lab-aurora-ml-testing-sa

Region *	us-east-2	□ Any
Account *	[redacted]	□ Any
Endpoint name *	docs-lab-aurora-ml-testing-sa	□ Any

5. Choose **Add** to save. Choose **Next: Tags** and **Next: Review** to get to the last page of the policy creation process.

6. Enter a Name and Description for this policy, and then choose **Create policy**. The policy is created and is added to the Policies list. You see an alert in the Console as this occurs.

7. On the IAM Console, choose **Roles**.

8. Choose **Create role**.

9. On the Select trusted entity page, choose the **AWS service** tile, and then choose **RDS** to open the selector.

10. Choose **RDS – Add Role to Database**.

11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**

12. **Next: Review**. Enter a name for the IAM role and a description.
13. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
14. Navigate to the AWS Region where your Aurora PostgreSQL DB cluster is located.
15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with SageMaker.
16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose SageMaker, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing.

The IAM setup for SageMaker is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension.

Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker (Advanced)

To use SageMaker with your own models rather than using the pre-built components provided by SageMaker, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket for Aurora PostgreSQL DB cluster to use. This is an advanced topic, and isn't fully documented in this *Amazon Aurora User Guide*. The general process is the same as for integrating support for SageMaker, as follows.

1. Create the IAM policy and role for Amazon S3.
2. Add the IAM role and the Amazon S3 import or export as a feature on the Connectivity & security tab of your Aurora PostgreSQL DB cluster.
3. Add the ARN of the role to your custom DB cluster parameter group for your Aurora DB cluster.

For basic usage information, see Exporting data to Amazon S3 for SageMaker model training (Advanced).

Installing the Aurora machine learning extension

The Aurora machine learning extensions `aws_ml 1.0` provides two functions that you can use to invoke Amazon Comprehend, SageMaker services and `aws_ml 2.0` provides two additional functions that you can use to invoke Amazon Bedrock services. Installing these extensions on your Aurora PostgreSQL DB cluster also creates an administrative role for the feature.

> **Note**
>
> Using these functions depends on having the IAM setup for the Aurora machine learning service (Amazon Comprehend, SageMaker, Amazon Bedrock) complete, as detailed in Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

- **aws_comprehend.detect_sentiment** – You use this function to apply sentiment analysis to text stored in in the database on your Aurora PostgreSQL DB cluster.
- **aws_sagemaker.invoke_endpoint** – You use this function in your SQL code to communicate with the SageMaker endpoint from your cluster.
- **aws_bedrock.invoke_model** – You use this function in your SQL code to communicate with the Bedrock Models from your cluster. The response of this function will be in the format of a TEXT, so if a model responds in the format of a JSON body then the output of this function will be relayed in the format of a string to the end user.
- **aws_bedrock.invoke_model_get_embeddings** – You use this function in your SQL code to invoke Bedrock Models that return output embeddings within a JSON response. This can be leveraged when you want to extract the embeddings directly associated with the json-key to streamline the response with any self-managed workflows.

To install the Aurora machine learning extension in your Aurora PostgreSQL DB cluster

- Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster. Connect to the specific database in which to install the `aws_ml` extension.

  ```
  psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
  port=5432 --username=postgres --password --dbname=labdb
  ```

```
labdb=> CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
labdb=>
```

Installing the aws_ml extensions also creates the aws_ml administrative role and two new schemas, as follows.

- aws_comprehend – Schema for the Amazon Comprehend service and source of the detect_sentiment function (aws_comprehend.detect_sentiment).
- aws_sagemaker – Schema for the SageMaker service and source of the invoke_endpoint function (aws_sagemaker.invoke_endpoint).
- aws_bedrock – Schema for the Amazon Bedrock service and source of the invoke_model(aws_bedrock.invoke_model) and invoke_model_get_embeddings(aws_bedrock.invoke_model_get_embeddings) functions.

The rds_superuser role is granted the aws_ml administrative role and is made the OWNER of these two Aurora machine learning schemas. To allow other database users to access the Aurora machine learning functions, the rds_superuser needs to grant EXECUTE privileges on the Aurora machine learning functions. By default, EXECUTE privileges are revoked from PUBLIC on the functions in the two Aurora machine learning schemas.

In a multi-tenant database configuration, you can prevent tenants from accessing Aurora machine learning functions by using REVOKE USAGE on the specific Aurora machine learning schema that you want to protect.

Using Amazon Bedrock with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Bedrock function for working with your text data. This function is available only after you install the aws_ml 2.0 extension and complete all setup procedures. For more information, see Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

aws_bedrock.invoke_model

This function takes text formatted in JSON as input and processes it for variety of models hosted on Amazon Bedrock and gets back the JSON text response from the model. This response could contain text, image, or embeddings. A summary of the function's documentation is as follows.

```
aws_bedrock.invoke_model(
   IN model_id      varchar,
   IN content_type  text,
   IN accept_type   text,
   IN model_input   text,
   OUT model_output varchar)
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model.
- `accept_type` – The type of the response to expect from Bedrock's model. Usually application/JSON for most of the models.
- `model_input` – Prompts; a specific set of inputs to the model in the format as specified by content_type. For more information on the request format/structure the model accepts, see Inference parameters for foundation models.
- `model_output` – The Bedrock model's output as text.

The following example shows how to invoke a Anthropic Claude 2 model for Bedrock using invoke_model.

Example Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model (
    model_id    := 'anthropic.claude-v2',
    content_type:= 'application/json',
    accept_type := 'application/json',
    model_input := '{"prompt": "\n\nHuman: You are a helpful assistant that answers
 questions directly and only using the information provided in the context below.
\nDescribe the answer
    in detail.\n\nContext: %s \n\nQuestion: %s \n
\nAssistant:","max_tokens_to_sample":4096,"temperature":0.5,"top_k":250,"top_p":0.5,"stop_seque
[]}'
);
```

aws_bedrock.invoke_model_get_embeddings

The model output can point to vector embeddings for some cases. Given the response varies per model, another function invoke_model_get_embeddings can be leveraged which works exactly like invoke_model but outputs the embeddings by specifying the appropriate json-key.

```
aws_bedrock.invoke_model_get_embeddings(
   IN model_id      varchar,
   IN content_type  text,
   IN json_key      text,
   IN model_input   text,
   OUT model_output float8[])
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model. Here, the accept_type is set to default value `application/json`.
- `model_input` – Prompts; a specific set of inputs to the Model in the format as specified by content_type. For more information on the request format/structure the Model accepts, see Inference parameters for foundation models.
- `json_key` – Reference to the field to extract the embedding from. This may vary if the embedding model changes.
- `model_output` – The Bedrock model's output as an array of embeddings having 16 bit decimals.

The following example shows how to generate an embedding using the Titan Embeddings G1 – Text embedding model for the phrase PostgreSQL I/O monitoring views.

Example Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model_get_embeddings(
   model_id      := 'amazon.titan-embed-text-v1',
   content_type  := 'application/json',
   json_key      := 'embedding',
   model_input   := '{ "inputText": "PostgreSQL I/O monitoring views"}') AS embedding;
```

Using Amazon Comprehend with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Comprehend function for working with your text data. This function is available only after you install the `aws_ml` extension and complete all setup procedures. For more information, see Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

aws_comprehend.detect_sentiment

This function takes text as input and evaluates whether the text has a a positive, negative, neutral, or mixed emotional posture. It outputs this sentiment along with a confidence level for its evaluation. A summary of the function's documentation is as follows.

```
aws_comprehend.detect_sentiment(
   IN input_text varchar,
   IN language_code varchar,
   IN max_rows_per_batch int,
   OUT sentiment varchar,
   OUT confidence real)
```

The inputs and outputs of this function are as follows.

- `input_text` – The text to evaluate and to assign sentiment (negative, positive, neutral, mixed).
- `language_code` – The language of the `input_text` identified using the 2-letter ISO 639-1 identifier with regional subtag (as needed) or the ISO 639-2 three-letter code, as appropriate. For example, `en` is the code for English, `zh` is the code for simplified Chinese. For more information, see Supported languages in the *Amazon Comprehend Developer Guide*.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions.
- `sentiment` – The sentiment of the input text, identified as POSITIVE, NEGATIVE, NEUTRAL, or MIXED.
- `confidence` – The degree of confidence in the accuracy of the specified `sentiment`. Values range from 0.0 to 1.0.

In the following, you can find examples of how to use this function.

Example Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes this function to assess customer satisfaction with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies the `aws_comprehend.detect_sentiment` function to the text in the `feedback` column of the table and outputs the sentiment and the confidence level for that sentiment. This query also outputs results in descending order.

```
SELECT feedback, s.sentiment,s.confidence
    FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
    ORDER BY s.confidence DESC;
 feedback                         | sentiment | confidence
 ---------------------------------------------------------+-----------+------------
 Thank you for the excellent customer support!            | POSITIVE  |   0.999771
 The latest version of this product stinks!               | NEGATIVE  |   0.999184
 Your support team is just awesome! I am blown away.      | POSITIVE  |   0.997774
 Your product is too complex, but your support is great.  | MIXED     |   0.957958
 Your support tech helped me in fifteen minutes.          | POSITIVE  |   0.949491
 My problem was never resolved!                           | NEGATIVE  |   0.920644
 When will the new version of this product be released?   | NEUTRAL   |   0.902706
 I cannot stand that chatbot.                             | NEGATIVE  |   0.895219
 Your support tech talked down to me.                     | NEGATIVE  |   0.868598
 It took me way too long to get a real person.            | NEGATIVE  |   0.481805

 (10 rows)
```

To avoid being charged for sentiment detection more than once per table row, you can materialize the results. Do this on the rows of interest. For example, the clinician's notes are being updated so that only those in French (`fr`) use the sentiment detection function.

```

UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
    confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE
    clinician_notes.french_notes IS NOT NULL AND
    LENGTH(TRIM(clinician_notes.french_notes)) > 0 AND
    clinician_notes.sentiment IS NULL;
```

For more information on optimizing your function calls, see Performance considerations for using Aurora machine learning with Aurora PostgreSQL.

Using SageMaker with your Aurora PostgreSQL DB cluster

After setting up your SageMaker environment and integrating with Aurora PostgreSQL as outlined in Setting up Aurora PostgreSQL to use Amazon SageMaker , you can invoke operations by using the `aws_sagemaker.invoke_endpoint` function. The `aws_sagemaker.invoke_endpoint` function connects only to a model endpoint in the same AWS Region. If your database instance has replicas in multiple AWS Regions be sure that you setup and deploy each SageMaker model to every AWS Region.

Calls to `aws_sagemaker.invoke_endpoint` are authenticated using the IAM role that you set up to associated your Aurora PostgreSQL DB cluster with the SageMaker service and the endpoint that you provided during the setup process. SageMaker model endpoints are scoped to an individual account and are not public. The `endpoint_name` URL doesn't contain the account ID. SageMaker determines the account ID from the authentication token that is supplied by the SageMaker IAM role of the database instance.

aws_sagemaker.invoke_endpoint

This function takes the SageMaker endpoint as input and the number of rows that should be processed as a batch. It also takes as input the various parameters expected by the SageMaker model endpoint. This function's reference documentation is as follows.

```
aws_sagemaker.invoke_endpoint(
  IN endpoint_name varchar,
  IN max_rows_per_batch int,
  VARIADIC model_input "any",
  OUT model_output varchar
  )
```

The inputs and outputs of this function are as follows.

- `endpoint_name` – An endpoint URL that is AWS Region–independent.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions.
- `model_input` – One or more input parameters for the model. These can be any data type needed by the SageMaker model. PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker model. The number of inputs to a SageMaker model is limited only by the SageMaker 6 MB message size limit.
- `model_output` – The SageMaker model's output as text.

Creating a user-defined function to invoke a SageMaker model

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker models. Your user-defined function represents the SageMaker endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

- You can give your SageMaker model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your SageMaker models.
- You can specify the model endpoint URL in just one place in your SQL application code.
- You can control `EXECUTE` privileges to each Aurora machine learning function independently.
- You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your SageMaker model and performs type conversion if necessary. Using SQL types will also translate `SQL NULL` to the appropriate default value expected by your SageMaker model.
- You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement `CREATE FUNCTION`. When you define the function, you specify the following:

- The input parameters to the model.
- The specific SageMaker endpoint to invoke.
- The return type.

The user-defined function returns the inference computed by the SageMaker endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker model with two input parameters.

```
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', NULL,
        arg1, arg2                        -- model inputs are separate arguments
        )::INT                            -- cast the output to INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- The aws_sagemaker.invoke_endpoint function input can be one or more parameters of any data type.
- This example uses an INT output type. If you cast the output from a varchar type to a different type, then it must be cast to a PostgreSQL builtin scalar type such as INTEGER, REAL, FLOAT, or NUMERIC. For more information about these types, see Data types in the PostgreSQL documentation.
- Specify PARALLEL SAFE to enable parallel query processing. For more information, see Improving response times with parallel query processing.
- Specify COST 5000 to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of cpu_operator_cost.

Passing an array as input to a SageMaker model

The aws_sagemaker.invoke_endpoint function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example defines a function that passes an array as input to the SageMaker regression model. The output is cast to a REAL value.

```
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
      'sagemaker_model_endpoint_name',
      NULL,
      params
      )::REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Specifying batch size when invoking a SageMaker model

The following example creates a user-defined function for a SageMaker model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```
CREATE FUNCTION classify_event (
    IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs
    max_rows_per_batch INT DEFAULT NULL,  -- optional batch size limit
    OUT category INT)                     -- model output
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', max_rows_per_batch,
        event_type, event_day, COALESCE(amount, 0.0)
        )::INT              -- casts output to type INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- Use the optional `max_rows_per_batch` parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see Understanding batch mode and Aurora machine learning functions.
- By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker. For this example the inputs have different types.
- If you have a non-text input, or text input that needs to default to some value other than an empty string, use the `COALESCE` statement. Use `COALESCE` to translate NULL to the desired null replacement value in the call to `aws_sagemaker.invoke_endpoint`. For the `amount` parameter in this example, a NULL value is converted to 0.0.

Invoking a SageMaker model that has multiple outputs

The following example creates a user-defined function for a SageMaker model that returns multiple outputs. Your function needs to cast the output of the `aws_sagemaker.invoke_endpoint` function to a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```
CREATE TYPE company_forecasts AS (
    six_month_estimated_return real,
    one_year_bankruptcy_probability float);
CREATE FUNCTION analyze_company (
    IN free_cash_flow NUMERIC(18, 6),
    IN debt NUMERIC(18,6),
    IN max_rows_per_batch INT DEFAULT NULL,
    OUT prediction company_forecasts)
```

```
AS $$
    SELECT (aws_sagemaker.invoke_endpoint('endpt_name',
       max_rows_per_batch,free_cash_flow, debt))::company_forecasts;

$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL ".*" notation.

Exporting data to Amazon S3 for SageMaker model training (Advanced)

We recommend that you become familiar with Aurora machine learning and SageMaker by using the provided algorithms and examples rather than trying to train your own models. For more information, see Get Started with Amazon SageMaker

To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker consumes the data from the Amazon S3 bucket for training. For more about SageMaker model training, see Train a model with Amazon SageMaker.

Note

When you create an Amazon S3 bucket for SageMaker model training or batch scoring, use `sagemaker` in the Amazon S3 bucket name. For more information, see Specify a Amazon S3 Bucket to Upload Training Datasets and Store Output Data in the *Amazon SageMaker Developer Guide*.

For more information about exporting your data, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.

Performance considerations for using Aurora machine learning with Aurora PostgreSQL

The Amazon Comprehend and SageMaker services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora PostgreSQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning from Aurora PostgreSQL.

Topics

Understanding batch mode and Aurora machine learning functions

Typically, PostgreSQL runs functions one row at a time. Aurora machine learning can reduce this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called *batch-mode execution*. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the `SELECT` list, a `WHERE` clause, or a `HAVING` clause. Note that top-level simple `CASE` expressions are eligible for batch-mode execution. Top-level searched `CASE` expressions are also eligible for batch-mode execution provided that the first `WHEN` clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a `LANGUAGE SQL` function and should specify `PARALLEL SAFE` and `COST 5000`.

Function migration from the SELECT statement to the FROM clause

Usually, an `aws_ml` function that is eligible for batch-mode execution is automatically migrated by Aurora to the `FROM` clause.

The migration of eligible batch-mode functions to the FROM clause can be examined manually on a per-query level. To do this, you use EXPLAIN statements (and ANALYZE and VERBOSE) and find the "Batch Processing" information below each batch-mode `Function Scan`. You can also use EXPLAIN (with VERBOSE) without running the query. You then observe whether the calls to the function appear as a `Function Scan` under a nested loop join that was not specified in the original statement.

In the following example, the nested loop join operator in the plan shows that Aurora migrated the anomaly_score function. It migrated this function from the SELECT list to the FROM clause, where it's eligible for batch-mode execution.

```
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
                         QUERY PLAN
-------------------------------------------------------------
 Nested Loop
   Output: anomaly_score((r.description)::text)
   ->  Seq Scan on ts.r
         Output: r.id, r.description, r.score
   ->  Function Scan on public.anomaly_score
         Output: anomaly_score.anomaly_score
         Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the apg_enable_function_migration parameter to false. This prevents the migration of aws_ml functions from the SELECT to the FROM clause. The following shows how.

```
SET apg_enable_function_migration = false;
```

The apg_enable_function_migration parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL apg_plan_mgmt extension for query plan management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its apg_enable_function_migration setting. This enforcement occurs regardless of the apg_enable_function_migration GUC parameter setting. For more information, see Managing query execution plans for Aurora PostgreSQL.

Using the max_rows_per_batch parameter

Both the aws_comprehend.detect_sentiment and the aws_sagemaker.invoke_endpoint functions have a max_rows_per_batch parameter. This parameter specifies the number of rows that can be sent to the Aurora machine learning service. The larger the dataset processed by your function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a SELECT statement finishes early due to a LIMIT clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your AWS account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the max_rows_per_batch parameter in your function calls.

If you do an EXPLAIN (VERBOSE, ANALYZE) of a query that uses batch-mode execution, you see a FunctionScan operator that is below a nested loop join. The number of loops reported by EXPLAIN equals the number of times a row was fetched from the FunctionScan operator. If a statement uses a LIMIT clause, the number of fetches is consistent. To optimize the size of the batch, set the max_rows_per_batch parameter to this value. However, if the batch-mode function is referenced in a predicate in the WHERE clause or HAVING clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with max_rows_per_batch to find a setting that optimizes performance.

Verifying batch-mode execution

To see if a function ran in batch mode, use EXPLAIN ANALYZE. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
 Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
                                avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the max_rows_per_batch parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a LIMIT in your user-defined function, set the max_rows_per_batch parameter to a smaller value.

Improving response times with parallel query processing

To get results as fast as possible from a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for `SELECT`, `CREATE TABLE AS SELECT`, and `CREATE MATERIALIZED VIEW` statements.

> **Note**
>
> PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the task among a set of parallel workers. Then each of these workers can build batched requests containing tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the SageMaker endpoint. The degree of parallelism that the endpoint can support is constrained by the number and type of instances that support it. For *K* degrees of parallelism, you need a database instance class that has at least *K* cores. You also need to configure the SageMaker endpoint for your model to have *K* initial instances of a sufficiently high-performing instance class.

To use parallel query processing, you can set the `parallel_workers` storage parameter of the table that contains the data that you plan to pass. You set `parallel_workers` to a batch-mode function such as `aws_comprehend.detect_sentiment`. If the optimizer chooses a parallel query plan, the AWS ML services can be called both in batch and in parallel.

You can use the following parameters with the `aws_comprehend.detect_sentiment` function to get a plan with four-way parallelism. If you change either of the following two parameters, you must restart the database instance for the changes to take effect

```
-- SET max_worker_processes to 8;  -- default value is 8
-- SET max_parallel_workers to 8;  -- not greater than max_worker_processes
SET max_parallel_workers_per_gather to 4;  -- not greater than max_parallel_workers

-- You can set the parallel_workers storage parameter on the table that the data
-- for the Aurora machine learning function is coming from in order to manually
 override the degree of
-- parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);

-- Example query to exploit both batch-mode execution and parallel query
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en')).*
FROM yourTable
WHERE id < 100;
```

For more information about controlling parallel query, see Parallel plans in the PostgreSQL documentation.

Using materialized views and materialized columns

When you invoke an AWS service such as SageMaker or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the AWS service into a materialized column so that the AWS service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an AWS service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.

`UPDATE` takes a row-level lock that can impact a running application. So you might need to use `SELECT ... FOR UPDATE SKIP LOCKED`, or use `MATERIALIZED VIEW`.

Analytic queries that operate on a large number of rows in real time can combine batch-mode materialization with real-time processing. To do this, these queries assemble a `UNION ALL` of the pre-materialized results with a query over the rows that don't yet have materialized results. In some cases, such a `UNION ALL` is needed in multiple places, or the query is generated by a third-party application. If so, you can create a `VIEW` to encapsulate the `UNION ALL` operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary `SELECT` statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the `CONCURRENTLY` option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

Monitoring Aurora machine learning

You can monitor the `aws_ml` functions by setting the `track_functions` parameter in your custom DB cluster parameter group to `all`. By default, this parameter is set to `pl` which means that only procedure-language functions are tracked. By changing this to `all`, the `aws_ml` functions are also tracked. For more information, see Run-time Statistics in the PostgreSQL documentation.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see Monitor Amazon SageMaker in the *Amazon SageMaker Developer Guide*.

With `track_functions` set to `all`, you can query the `pg_stat_user_functions` view to get statistics about the functions that you define and use to invoke Aurora machine learning services. For each function, the view provides the number of `calls`, `total_time`, and `self_time`.

To view the statistics for the `aws_sagemaker.invoke_endpoint` and the `aws_comprehend.detect_sentiment` functions, you can filter results by schema name using the following query.

```
SELECT * FROM pg_stat_user_functions
    WHERE schemaname
    LIKE 'aws_%';
```

To clear the statistics, do as follows.

```
SELECT pg_stat_reset();
```

You can get the names of your SQL functions that call the `aws_sagemaker.invoke_endpoint` function by querying the PostgreSQL `pg_proc` system catalog. This catalog stores information about functions, procedures, and more. For more information, see pg_proc in the PostgreSQL documentation. Following is an example of querying the table to get the names of functions (`proname`) whose source (`prosrc`) includes the text *invoke_endpoint*.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

Code examples for Aurora using AWS SDKs

The following code examples show how to use Aurora with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Cross-service examples are sample applications that work across multiple AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

.NET

AWS SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
```

```
namespace AuroraActions;

public static class HelloAurora
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the
        // Amazon Relational Database Service (Amazon RDS).
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonRDS>()
            ).Build();

        // Now the client is available for injection. Fetching it directly here
 for example purposes only.
        var rdsClient = host.Services.GetRequiredService<IAmazonRDS>();

        // You can use await and any of the async methods to get a response.
        var response = await rdsClient.DescribeDBClustersAsync(new
 DescribeDBClustersRequest { IncludeShared = true });
        Console.WriteLine($"Hello Amazon RDS Aurora! Let's list some clusters in
 this account:");
        foreach (var cluster in response.DBClusters)
        {
            Console.WriteLine($"\tCluster: database: {cluster.DatabaseName}
 identifier: {cluster.DBClusterIdentifier}.");
        }
    }
}
```

- For API details, see DescribeDBClusters in *AWS SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
project("hello_aurora")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
 libraries for the AWS SDK.
    string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
 "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD AND AWSSDK_INSTALL_AS_SHARED_LIBS)
     # Copy relevant AWS SDK for C++ libraries into the current binary directory
 for running and debugging.
```

```
     # set(BIN_SUB_DIR "/Debug") # If you are building from the command line, you
 may need to uncomment this
                                    # and set the proper subdirectory to the
 executables' location.

     AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""

Actions for Aurora using AWS SDKs

The following code examples demonstrate how to perform individual Aurora actions with AWS SDKs. These excerpts call the Aurora API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Aurora API Reference.

Examples

- Use DescribeDBClusters with an AWS SDK or CLI
- Use DescribeDBEngineVersions with an AWS SDK or CLI
- Use DescribeDBInstances with an AWS SDK or CLI
- Use DescribeOrderableDBInstanceOptions with an AWS SDK or CLI
- Use ModifyDBClusterParameterGroup with an AWS SDK or CLI

Use `CreateDBCluster` with an AWS SDK or CLI

The following code examples show how to use `CreateDBCluster`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters

Use `DeleteDBCluster` with an AWS SDK or CLI

The following code examples show how to use `DeleteDBCluster`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters

.NET

AWS SDK for .NET

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteDBInstance` with an AWS SDK or CLI

The following code examples show how to use `DeleteDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters

.NET

PowerShell

Tools for PowerShell

Example 1: This example lists the DB engine versions that support a specific DB instance class in an AWS Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  DBInstanceClass = 'db.r5.large'
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

Example 2: This example lists the DB instance classes that are supported for a specific DB engine version in an AWS Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  EngineVersion = '13.6'
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

- For API details, see ModifyDBClusterParameterGroup in *AWS SDK for Rust API reference*.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for Aurora using AWS SDKs

The following code examples show you how to implement common scenarios in Aurora with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Aurora. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- Get started with Aurora DB clusters using an AWS SDK

Get started with Aurora DB clusters using an AWS SDK

The following code examples show how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using AuroraActions;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
using Microsoft.Extensions.Logging;
using Microsoft.Extensions.Logging.Console;
using Microsoft.Extensions.Logging.Debug;

namespace AuroraScenario;

/// <summary>
/// Scenario for Amazon Aurora examples.
/// </summary>
public class AuroraScenario
{
    /*
```

```
   Before running this .NET code example, set up your development environment,
including your credentials.

   This .NET example performs the following tasks:
   1.  Return a list of the available DB engine families for Aurora MySql using
the DescribeDBEngineVersionsAsync method.
   2.  Select an engine family and create a custom DB cluster parameter group
using the CreateDBClusterParameterGroupAsync method.
   3.  Get the parameter group using the DescribeDBClusterParameterGroupsAsync
method.
   4.  Get some parameters in the group using the
DescribeDBClusterParametersAsync method.
   5.  Parse and display some parameters in the group.
   6.  Modify the auto_increment_offset and auto_increment_increment parameters
       using the ModifyDBClusterParameterGroupAsync method.
   7.  Get and display the updated parameters using the
DescribeDBClusterParametersAsync method with a source of "user".
   8.  Get a list of allowed engine versions using the
DescribeDBEngineVersionsAsync method.
   9.  Create an Aurora DB cluster that contains a MySql database and uses the
parameter group.
       using the CreateDBClusterAsync method.
   10. Wait for the DB cluster to be ready using the DescribeDBClustersAsync
method.
   11. Display and select from a list of instance classes available for the
selected engine and version
       using the paginated DescribeOrderableDBInstanceOptions method.
   12. Create a database instance in the cluster using the CreateDBInstanceAsync
method.
   13. Wait for the DB instance to be ready using the DescribeDBInstances
method.
   14. Display the connection endpoint string for the new DB cluster.
   15. Create a snapshot of the DB cluster using the
CreateDBClusterSnapshotAsync method.
   16. Wait for DB snapshot to be ready using the
DescribeDBClusterSnapshotsAsync method.
   17. Delete the DB instance using the DeleteDBInstanceAsync method.
   18. Delete the DB cluster using the DeleteDBClusterAsync method.
   19. Wait for DB cluster to be deleted using the DescribeDBClustersAsync
methods.
   20. Delete the cluster parameter group using the
DeleteDBClusterParameterGroupAsync.

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
// GetStartedClusters is an interactive example that shows you how to use the AWS
 SDK for Go
// with Amazon Aurora to do the following:
//
// 1. Create a custom DB cluster parameter group and set parameter values.
// 2. Create an Aurora DB cluster that is configured to use the parameter group.
// 3. Create a DB instance in the DB cluster that contains a database.
// 4. Take a snapshot of the DB cluster.
// 5. Delete the DB instance, DB cluster, and parameter group.

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
 * by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
 * 2. Selects an engine family and creates a custom DB cluster parameter group
 * by invoking the describeDBClusterParameters method.
 * 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
 * method.
 * 4. Gets parameters in the group by invoking the describeDBClusterParameters
 * method.
 * 5. Modifies the auto_increment_offset parameter by invoking the
 * modifyDbClusterParameterGroupRequest method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the
 * describeDbEngineVersions method.
 * 8. Creates an Aurora DB cluster database cluster that contains a MySQL
 * database.
 * 9. Waits for DB instance to be ready.
 * 10. Gets a list of instance classes available for the selected engine.
 * 11. Creates a database instance in the cluster.
 * 12. Waits for DB instance to be ready.
 * 13. Creates a snapshot.
 * 14. Waits for DB snapshot to be ready.
 * 15. Deletes the DB cluster.
 * 16. Deletes the DB cluster group.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
Before running this Kotlin code example, set up your development environment,
 including your credentials.

For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

This example requires an AWS Secrets Manager secret that contains the database
 credentials. If you do not create a
secret, this example will not work. For more details, see:

https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html

This Kotlin example performs the following tasks:

1. Returns a list of the available DB engines.
2. Creates a custom DB parameter group.
3. Gets the parameter groups.
4. Gets the parameters in the group.
5. Modifies the auto_increment_increment parameter.
6. Displays the updated parameter value.
7. Gets a list of allowed engine versions.
8. Creates an Aurora DB cluster database.
9. Waits for DB instance to be ready.
10. Gets a list of instance classes available for the selected engine.
```

```
11. Creates a database instance in the cluster.
12. Waits for the database instance in the cluster to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB instance.
16. Deletes the DB cluster.
17. Deletes the DB cluster group.
 */

Cross-service examples for Aurora using AWS SDKs

The following sample applications use AWS SDKs to combine Aurora with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

Examples

- Create a lending library REST API
- Create an Aurora Serverless work item tracker

Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and AWS Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.
- Use AWS Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.
- Use AWS Chalice to deploy a serverless REST API to Amazon API Gateway and AWS Lambda.

- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

AWS SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

Database engine	Best practices
Amazon Aurora MySQL	See Best practices with Amazon Aurora MySQL
Amazon Aurora PostgreSQL	See Best practices with Amazon Aurora PostgreSQL

Note

For common recommendations for Aurora, see Viewing and responding to Amazon Aurora recommendations.

Topics

- Basic operational guidelines for Amazon Aurora
- DB instance RAM recommendations
- AWS database drivers
- Monitoring Amazon Aurora
- Working with DB parameter groups and DB cluster parameter groups
- Amazon Aurora best practices video

Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:

- `VolumeReadIOPS` – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of `VolumeReadIOPS` should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

  > **Tip**
  >
  > If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

- `BufferCacheHitRatio` – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory.

A high hit ratio indicates that your DB instance has enough memory available. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. Investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

For more information, see Amazon CloudWatch metrics for Amazon Aurora.

AWS database drivers

We recommend the AWS suite of drivers for application connectivity. The drivers have been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the AWS suite of drivers is to have built-in support for these service features.

For more information, see Connecting to Aurora DB clusters with the AWS drivers.

Monitoring Amazon Aurora

Amazon Aurora provides various metrics and insights that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the AWS Management Console, AWS CLI, and CloudWatch API, to view Aurora metrics. You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see Viewing combined metrics in the Amazon RDS console.

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, Creating a performance analysis report.

Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see Backing up and restoring an Amazon Aurora DB cluster.

Amazon Aurora best practices video

The AWS Online Tech Talks channel on YouTube includes a video presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. See Amazon Aurora best practices for high availability.

Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as Managing performance and scaling for Aurora DB clusters, Amazon Aurora MySQL performance enhancements, Managing Amazon Aurora PostgreSQL, and Monitoring DB load with Performance Insights on Amazon Aurora.

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your AWS representative to see if there are Aurora best practices or case studies for your type of application.

1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as *provisioned*. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the AWS Database Blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads. Another might be demand-based scaling, described in Using Amazon Aurora Auto Scaling with Aurora Replicas in the *Amazon Aurora User Guide.* Others might be performance gains or simplified database operations.

2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. *High velocity* involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 `SELECT` statements per second. Again depending on workload, such a cluster can process 200,000 `INSERT`, `UPDATE`, and `DELETE` statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 replicas, each of which is on average within 10–20 milliseconds of the primary instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other AWS services, the AWS Management Console, and the AWS CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

3. Practice with the AWS Management Console or AWS CLI

As a next step, practice with the AWS Management Console or the AWS CLI, to become familiar with these tools and with Aurora.

Practice with the AWS Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the AWS Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see Replication with Amazon Aurora. Scale the DB instances up or down by changing the AWS instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the AWS Management Console in the beginning. After you understand what you can do with Aurora, you can progress to automating those operations using the AWS CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

Practice with the AWS CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the AWS CLI if you're not already. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as AWS CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the AWS CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see Update behaviors of stack resources in the *AWS CloudFormation User Guide.*

4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see Creating an Amazon Aurora DB cluster.

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Turn off **Easy create**. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Use a recent DB engine version. These combinations of database engine and version have wide compatibility with other Aurora features and substantial customer usage for production applications.
  - Aurora MySQL version 3.x (MySQL 8.0 compatibility)
  - Aurora PostgreSQL version 15.x or 16.x
- Choose the **Dev/Test** template. This choice isn't significant for your proof-of-concept activities.
- For **DB instance class**, choose **Memory optimized classes** and one of the **xlarge** instance classes. You can adjust the instance class up or down later.
- Under **Multi-AZ Deployment**, choose **Create an Aurora Replica or Reader node in a different AZ**. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "writer," because different DB instances assume those roles as needed. We recommend using something like `clustername-az-serialnumber`, for example `myprodappdb-a-01`. These pieces uniquely identify the DB instance and its placement.
- Set the backup retention high for the Aurora cluster. With a long retention period, you can do point-in-time recovery (PITR) for a period up to 35 days. You can reset your database to a known state after running tests involving DDL and data manipulation language (DML) statements. You can also recover if you delete or change data by mistake.
- Turn on additional recovery, logging, and monitoring features at cluster creation. Turn on all the choices that are available under **Backtrack**, **Performance Insights**, **Monitoring**, and **Log exports**. With these features enabled, you can test the suitability of features such as backtracking, Enhanced Monitoring, or Performance Insights for your workload. You can also easily investigate performance and perform troubleshooting during the proof of concept.

5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the **Connectivity** tab of the detail page of your cluster. The cluster endpoint is the one labeled **Writer**. The other endpoint, labeled **Reader**, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see Connecting to an Amazon Aurora DB cluster.

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the AWS Schema Conversion Tool (AWS SCT) to simplify the process. For details, see the AWS Schema Conversion Tool User Guide. For general details about migration and porting activities, see the Migrating Your Databases to Amazon Aurora AWS whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see Migrating data to an Amazon Aurora MySQL DB cluster or Migrating data to Amazon Aurora with PostgreSQL compatibility depending on the database engine you're using in the proof of concept.

Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the AWS Database Migration Service (AWS DMS). For details about AWS DMS, see the AWS Database Migration Service User Guide.

For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the AWS SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see 9. Connect to Aurora.

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in Introducing the Aurora storage engine on the AWS Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see Amazon Aurora DB cluster and DB instance parameters. For the configuration settings that are or aren't applicable to Aurora clusters, see Aurora MySQL configuration parameters or Amazon Aurora PostgreSQL parameters depending on your database engine.

9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as `SELECT` statement, or a write such as a `CREATE` or `INSERT` statement. As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the *primary instance*. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing `SELECT` statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

> **Note**
>
> Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle `SELECT` statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.
- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.
- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.

- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.

For general information about connection management and endpoints for Aurora, see Connecting to an Amazon Aurora DB cluster. For a deep dive on this subject, see Aurora MySQL database administrator's handbook – Connection management.

10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same AWS Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on AWS Regions, see Regions and Availability Zones in the *Amazon RDS User Guide.* To learn more about the Amazon VPC service, see What is Amazon VPC? in the *Amazon VPC User Guide.*

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in 8. Specify configuration settings.

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different AWS instance classes, numbers of AWS Replicas, and so on.

Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see Creating a DB cluster snapshot and Restoring from a DB cluster snapshot.

11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the **Monitoring** tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

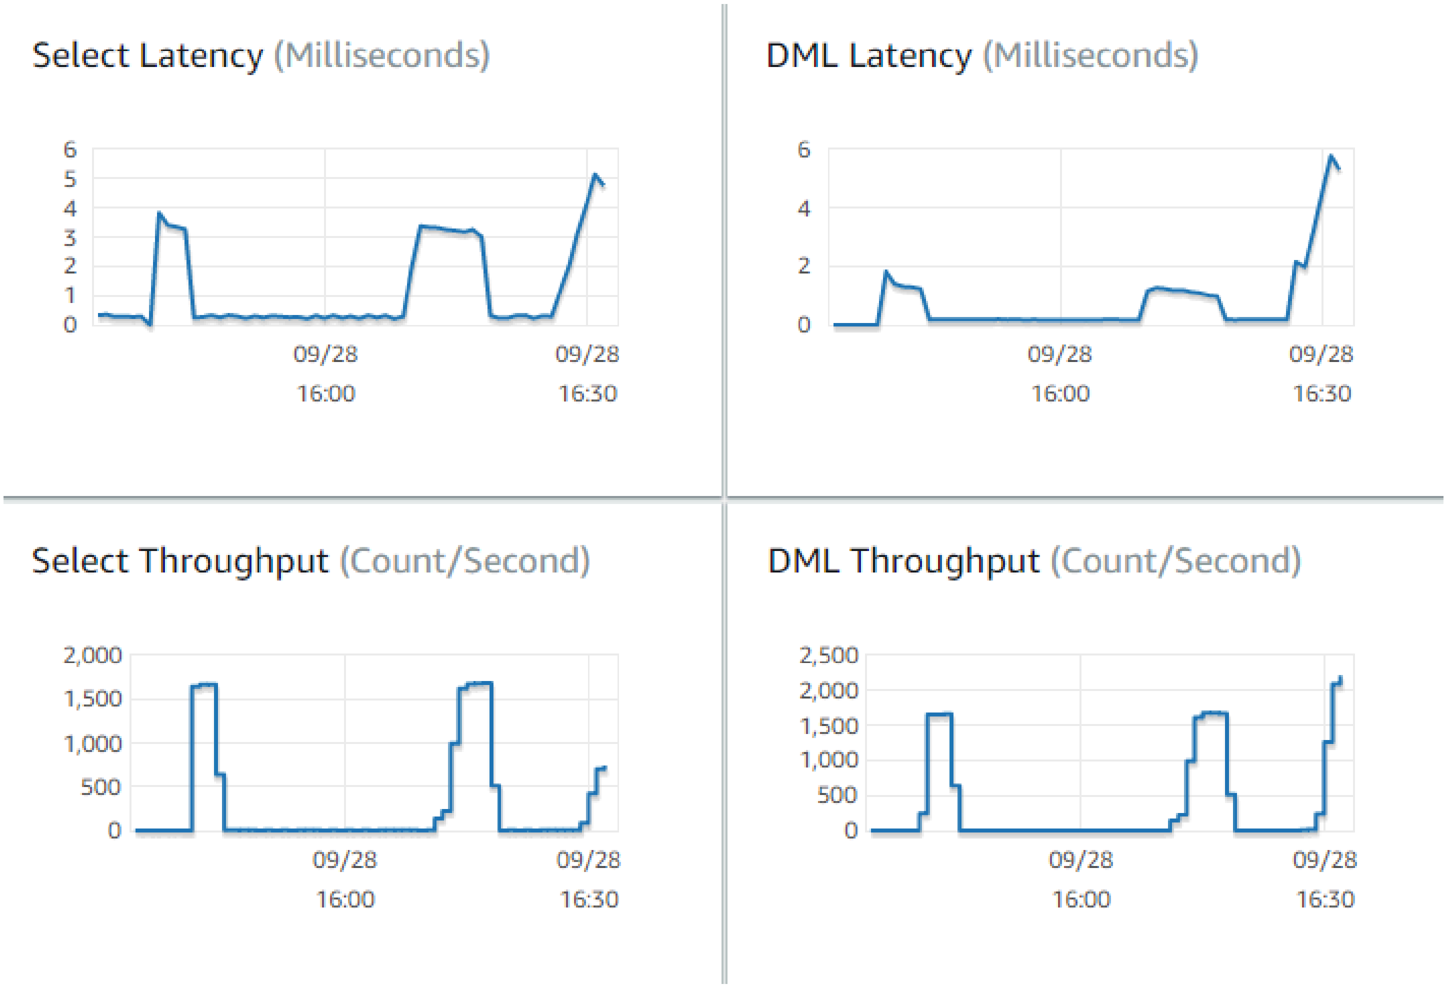
To have more choices on the **Monitoring** tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the **Monitoring** tab for that specific instance.

After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To do so, look at the **Monitoring** tab for a given Aurora cluster in the Amazon RDS console as illustrated following.



If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

Tip

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

Tip

Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the `SELECT` queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add

DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

> **Tip**
>
> For a proof of concept, set up all the DB instances in an Aurora cluster with the same AWS instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your AWS Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

> **Tip**
>
> The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.
> When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see Testing Amazon Aurora MySQL using fault injection queries.

As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for `SELECT` queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only `SELECT` statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other AWS Regions and restore into other AWS Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore AWS services and features such as AWS Secrets Manager and AWS Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see Managing performance and scaling for Aurora DB clusters, Amazon Aurora MySQL performance enhancements, Managing Amazon Aurora PostgreSQL, and Monitoring DB load with Performance Insights on Amazon Aurora. If you do additional tuning, make sure that you're familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the AWS whitepaper Aurora MySQL database administrator's handbook – Connection management.

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other AWS services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. AWS services that address such use cases include the following:
  - Amazon Redshift

  - Amazon EMR
  - Amazon Athena
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - AWS Glue
  - AWS DMS
  - Importing from Amazon S3, as described in the *Amazon Aurora User Guide*
  - Exporting to Amazon S3, as described in the *Amazon Aurora User Guide*
  - Many other popular ETL tools

Security in Amazon Aurora

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon Aurora (Aurora), see AWS services in scope by compliance program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see Amazon VPC VPCs and Amazon Aurora.
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

  To review IAM policy examples, see Identity-based policy examples for Amazon Aurora.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see Using SSL/TLS to encrypt a connection to a DB cluster.
- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see Encrypting Amazon Aurora resources.
- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

  For information about security with Aurora MySQL, see Security with Amazon Aurora MySQL. For information about security with Aurora PostgreSQL, see Security with Amazon Aurora PostgreSQL.

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the *Amazon RDS user guide*.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the AWS CLI to access the RDS API interactively. Some RDS API operations and AWS CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see Amazon RDS API reference. For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

> **Note**
>
> You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, automatic failover, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

Topics

- Database authentication with Amazon Aurora
- Password management with Amazon Aurora and AWS Secrets Manager
- Data protection in Amazon RDS
- Identity and access management for Amazon Aurora
- Logging and monitoring in Amazon Aurora
- Compliance validation for Amazon Aurora

Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL and Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

> ⚠ **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics

- Password authentication
- IAM database authentication
- Kerberos authentication

Password authentication

With *password authentication,* your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER` *`name`* `IDENTIFIED BY` *`password`*, while in PostgreSQL, the statement is `CREATE USER` *`name`* `WITH PASSWORD` *`password`*.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication.

Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

You can make it possible for your database users to authenticate against DB clusters in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Aurora PostgreSQL doesn't support selective authentication type in forest trust, only forest wide authentication.

Aurora supports Kerberos authentication for Aurora MySQL and Aurora PostgreSQL DB clusters. For more information about Kerberos authentication for Aurora MySQL, see Using Kerberos authentication for Aurora MySQL.

With Kerberos authentication, Aurora PostgreSQL DB clusters support one- and two-way forest trust relationships. For more information, see Using Kerberos authentication with Aurora PostgreSQL.

Password management with Amazon Aurora and AWS Secrets Manager

Amazon Aurora integrates with Secrets Manager to manage master user passwords for your DB clusters.

Topics

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon Aurora, see Supported Regions and Aurora DB engines for Secrets Manager integration.

Limitations for Secrets Manager integration with Amazon Aurora

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Amazon RDS Blue/Green Deployments
- DB clusters that are part of an Aurora global database
- Aurora Serverless v1 DB clusters
- Aurora MySQL cross-Region read replicas
- Managing master user password with Secrets Manager for a read replica

Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

When you store database secrets in Secrets Manager, your AWS account incurs charges. For information about pricing, see AWS Secrets Manager Pricing.

You can specify that Aurora manages the master user password in Secrets Manager for an Amazon Aurora DB cluster when you perform one of the following operations:

- Create the DB cluster
- Modify the DB cluster
- Restore the DB cluster from Amazon S3 (Aurora MySQL only)

When you specify that Aurora manages the master user password in Secrets Manager, Aurora generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

Aurora manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB cluster that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the *AWS Secrets Manager User Guide*.

Benefits of managing master user passwords with Secrets Manager

Managing Aurora master user passwords with Secrets Manager provides the following benefits:

- Aurora automatically generates database credentials.
- Aurora automatically stores and manages database credentials in AWS Secrets Manager.

- Aurora rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon Aurora.

For create, modify, or restore operations, the user who specifies that Aurora manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`
- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

Enforcing Aurora management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce Aurora management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by Aurora in Secrets Manager.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
 "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "rds:ManageMasterUserPassword": false
                }
            }
        }
    ]
}
```

Note

This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the cluster.
To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing clusters that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see Policy condition keys for Aurora and Example policies: Using condition keys.

Managing the master user password for a DB cluster with Secrets Manager

You can configure Aurora management of the master user password in Secrets Manager when you perform the following actions:

- Creating an Amazon Aurora DB cluster
- Modifying an Amazon Aurora DB cluster
- Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

Console

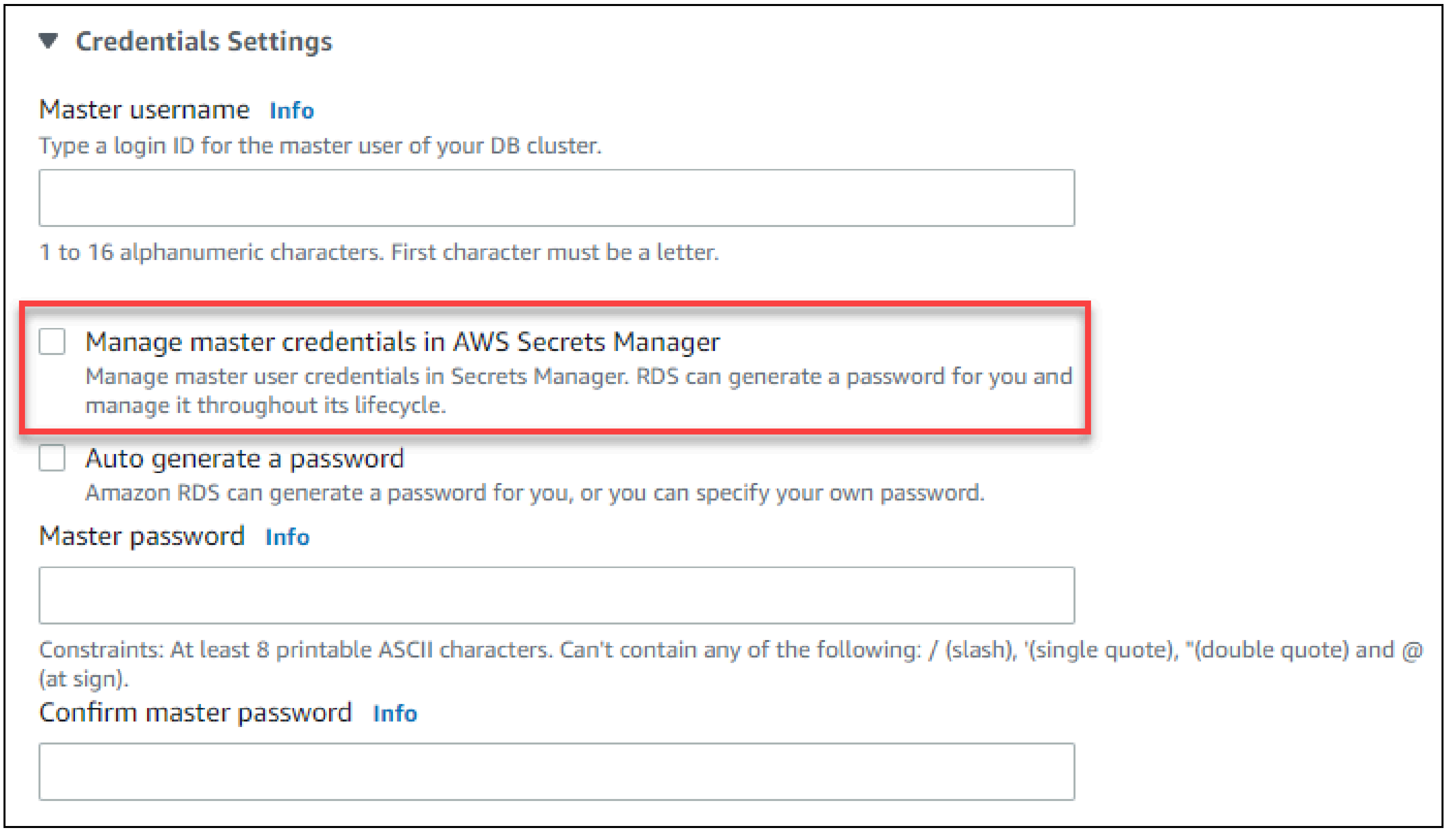
Follow the instructions for creating or modifying a DB cluster with the RDS console:

- Creating a DB cluster
- Modifying a DB instance in a DB cluster

  In the RDS console, you can modify any DB instance to specify the master user password management settings for the entire DB cluster.
- Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by Aurora in Secrets Manager. To do so when you are creating or restoring a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating or restoring a DB cluster.



▼ Credentials Settings

Master username Info

Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

□ Manage master credentials in AWS Secrets Manager

Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

□ Auto generate a password

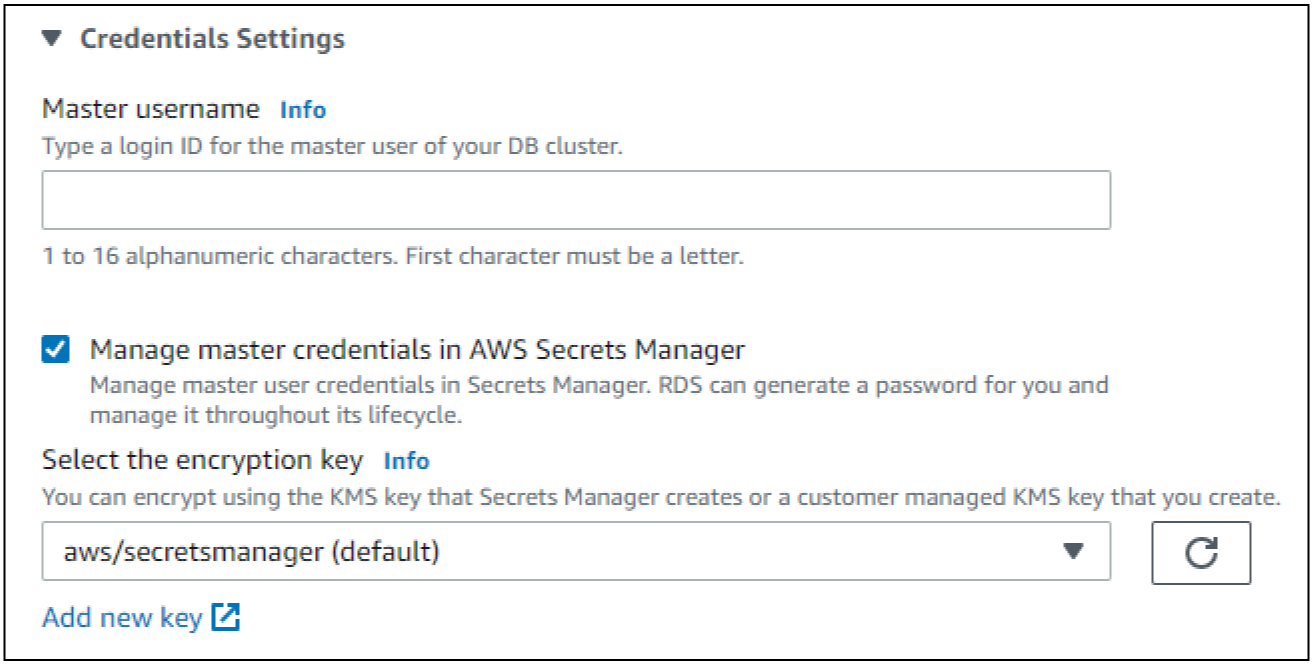
Amazon RDS can generate a password for you, or you can specify your own password.

Master password Info

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm master password Info

When you select this option, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.



▼ Credentials Settings

Master username Info

Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

☑ Manage master credentials in AWS Secrets Manager

Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

Select the encryption key Info

You can encrypt using the KMS key that Secrets Manager creates or a customer managed KMS key that you create.

aws/secretsmanager (default) ▼

Add new key

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters. For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora.

AWS CLI

To specify that Aurora manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- create-db-cluster
- modify-db-cluster
- restore-db-cluster-from-s3

When you specify the `--manage-master-user-password` option in these commands, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters. For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora.

This example creates a DB cluster and specifies that Aurora manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
     --db-cluster-identifier sample-cluster \
     --engine aurora-mysql \
     --engine-version 8.0 \
     --master-username admin \
     --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^
     --db-cluster-identifier sample-cluster ^
     --engine aurora-mysql ^
     --engine-version 8.0 ^
     --master-username admin ^
     --manage-master-user-password
```

RDS API

To specify that Aurora manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- CreateDBCluster
- ModifyDBCluster
- RestoreDBClusterFromS3

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB cluster

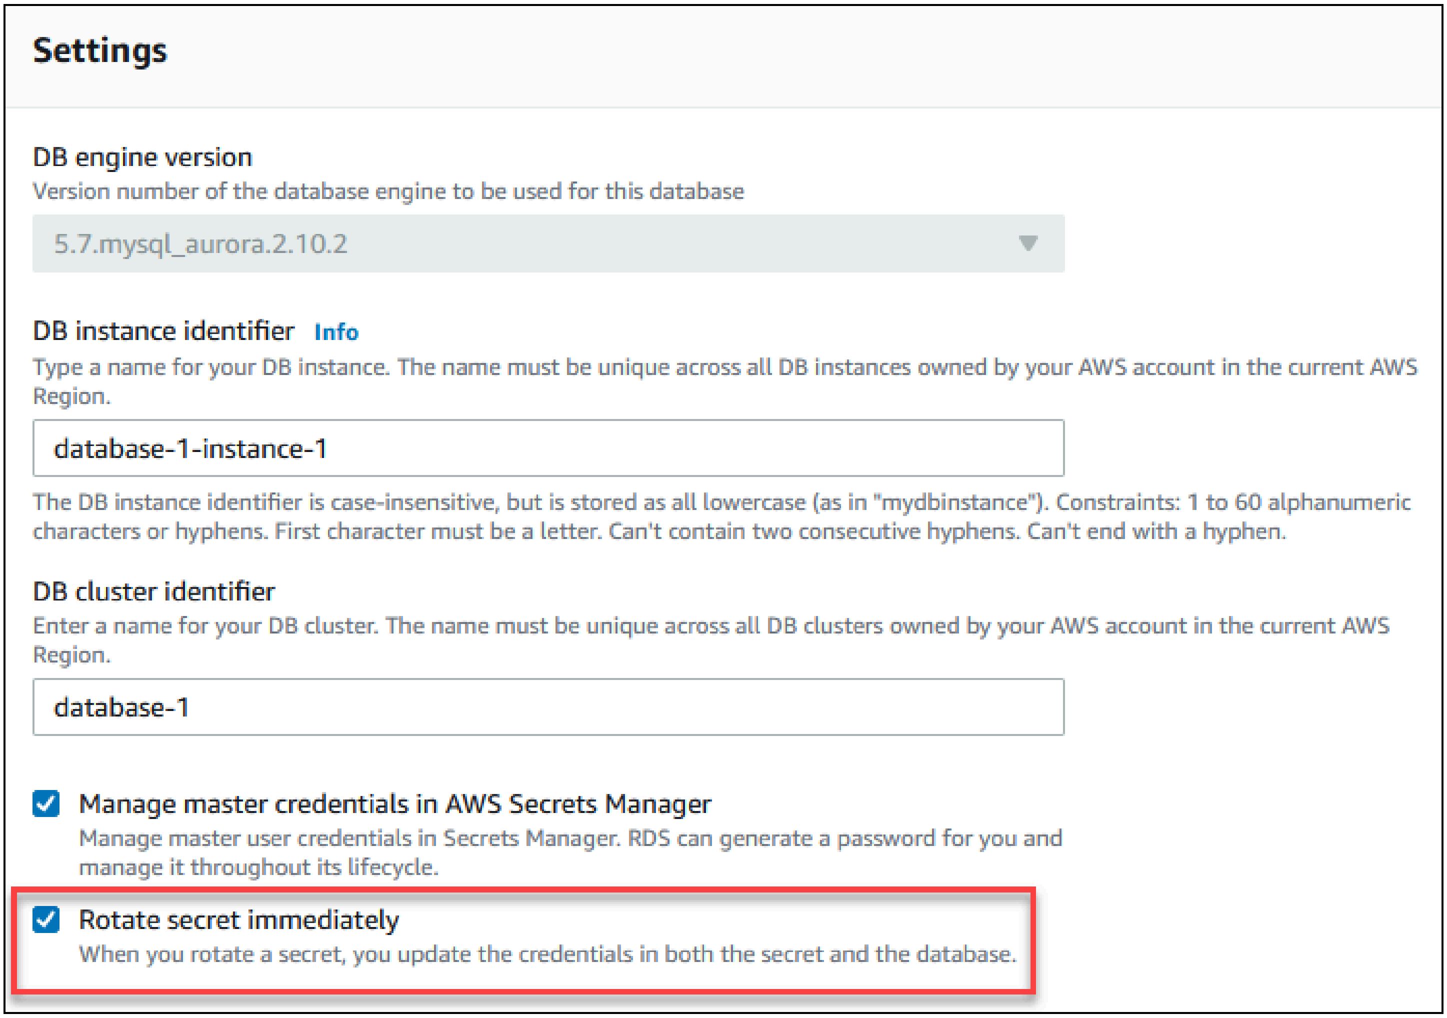
When Aurora rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Aurora changes the master user password for the DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB cluster. For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains atleast one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the DB cluster and select **Rotate secret immediately** in **Settings**.



Settings

DB engine version
Version number of the database engine to be used for this database

5.7.mysql_aurora.2.10.2 ▼

DB instance identifier Info
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1-instance-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

DB cluster identifier
Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

database-1

☑ Manage master credentials in AWS Secrets Manager
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

☑ Rotate secret immediately
When you rotate a secret, you update the credentials in both the secret and the database.

Follow the instructions for modifying a DB cluster with the RDS console in Modifying the DB cluster by using the console, CLI, and API. You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the modify-db-cluster command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --rotate-master-user-password \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

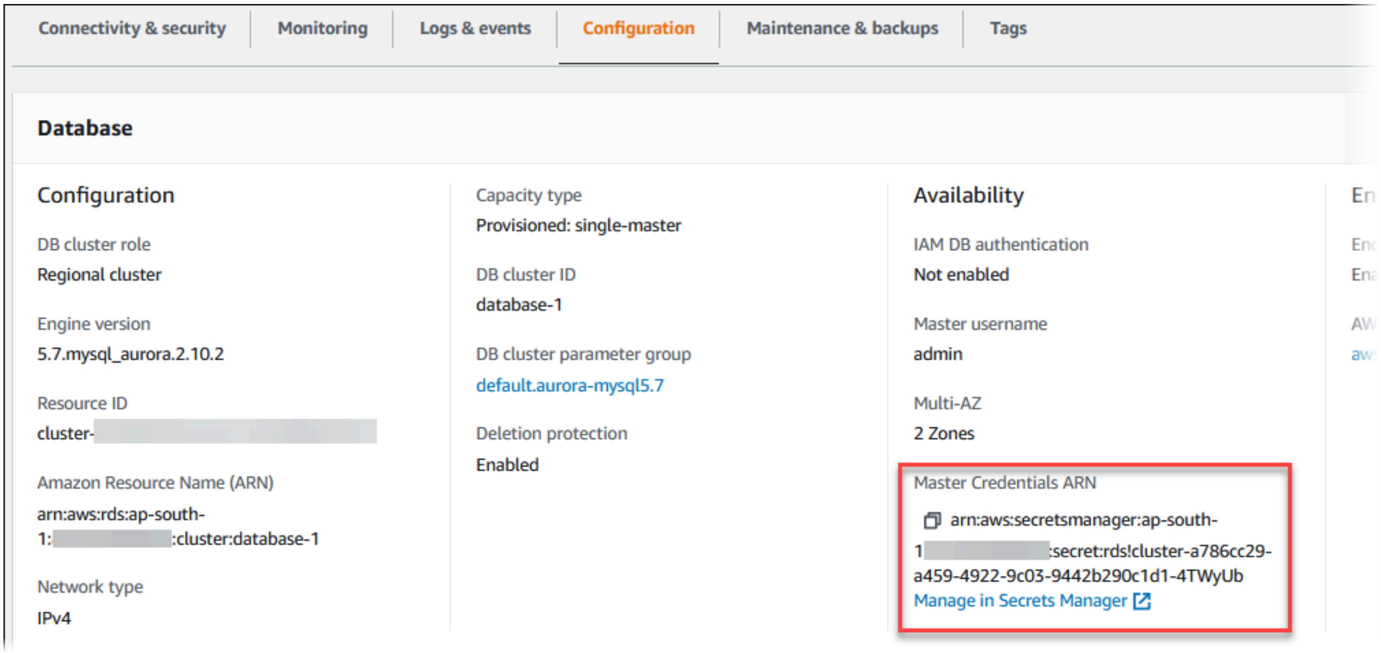
You can find the Amazon Resource Name (ARN) of a secret managed by Aurora in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by Aurora in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.



Database

Configuration

DB cluster role
Regional cluster

Engine version
5.7.mysql_aurora.2.10.2

Resource ID
cluster-[redacted]

Amazon Resource Name (ARN)
arn:aws:rds:ap-south-1:[redacted]:cluster:database-1

Manage in Secrets Manager

En

Enc
Ena

AW
aws

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the RDS AWS CLI describe-db-clusters command to find the following information about a secret managed by Aurora in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the modify-db-cluster command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by Aurora in Secrets Manager using the DescribeDBClusters RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS

SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics

- Protecting data using encryption
- Internetwork traffic privacy

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

Topics

- Encrypting Amazon Aurora resources
- AWS KMS key management
- Using SSL/TLS to encrypt a connection to a DB cluster
- Rotating your SSL/TLS certificate

Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.

Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

> **Note**
>
> For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics

Overview of encrypting Amazon Aurora resources

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. You can also encrypt a read replica of an Amazon Aurora encrypted cluster. Amazon Aurora uses an AWS Key Management Service key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide* and AWS KMS key management. Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Encrypting an Amazon Aurora DB cluster

To encrypt a new DB cluster, choose **Enable encryption** on the console. For information on creating a DB cluster, see Creating an Amazon Aurora DB cluster.

If you use the create-db-cluster AWS CLI command to create an encrypted DB cluster, set the `--storage-encrypted` parameter. If you use the CreateDBCluster API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB cluster, you can choose a customer managed key or the AWS managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the AWS managed key for your new DB cluster. Amazon Aurora creates an AWS managed key for Amazon Aurora for your AWS account. Your AWS account has a different AWS managed key for Amazon Aurora for each AWS Region.

For more information about KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide*.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

If you use the AWS CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

⚠ **Important**

Amazon Aurora can lose access to the KMS key for a DB cluster when you disable the KMS key. In these cases, the encrypted DB cluster shortly goes into `inaccessible-encryption-credentials-recoverable` state. The DB cluster remains in this state for seven days, during which the instance is stopped. API calls made to the DB cluster during this time might not succeed. To recover the DB cluster, enable the KMS key and restart this DB cluster. Enable the KMS key from the AWS Management Console. Restart the DB cluster using the AWS CLI command start-db-cluster or AWS Management Console.
If the DB cluster isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB cluster is not usable anymore and you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups for encrypted DB clusters to guard against the loss of encrypted data in your databases.
During the creation of a DB cluster, Aurora checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the

DB cluster. Revoking the calling principals access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB cluster from the snapshot without specifying a different KMS key, the new cluster uses the KMS key from the source account. Revoking access to the key after you create the DB cluster does not affect the cluster. However, disabling the key impacts all DB clusters encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

Determining whether encryption is turned on for a DB cluster

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

Console

To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the **Configuration** tab and check the **Encryption** value.

   It shows either **Enabled** or **Not enabled**.

AWS CLI

To determine whether encryption at rest is turned on for a DB cluster by using the AWS CLI, call the describe-db-clusters command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either `TRUE` or `FALSE` regarding encryption at rest for the `mydb` DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "*[].
{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the DescribeDBClusters operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

> **Note**
>
> Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

Encryption in transit

AWS provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized**: R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same AWS Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't turn off encryption on an encrypted DB cluster.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.

- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.
- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

AWS KMS key management

Amazon Aurora automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

You can use two types of AWS KMS keys to encrypt your DB clusters.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see Customer managed keys in the *AWS Key Management Service Developer Guide*.

  You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.
- *AWS managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the *AWS Key Management Service Developer Guide*.

To manage KMS keys used for Amazon Aurora encrypted DB clusters, use the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use AWS CloudTrail. For more information about key rotation, see Rotating AWS KMS keys.

> ⚠ **Important**
>
> If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB cluster is no longer available, and the current state of the database can't be recovered. To restore the DB cluster, you must re-enable access to the KMS key for RDS, and then restore the DB cluster from the latest available backup.

Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- kms:CreateGrant
- kms:DescribeKey

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in Aurora, you can use the kms:ViaService condition key with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the Amazon RDS encryption context as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the *AWS Key Management Service Developer Guide* and Key policies in AWS KMS.

Amazon RDS encryption context

When Aurora uses your KMS key, or when Amazon EBS uses the KMS key on behalf of Aurora, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Aurora always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate,** for your database. For more information about certificate authorities, see Certificate authorities.

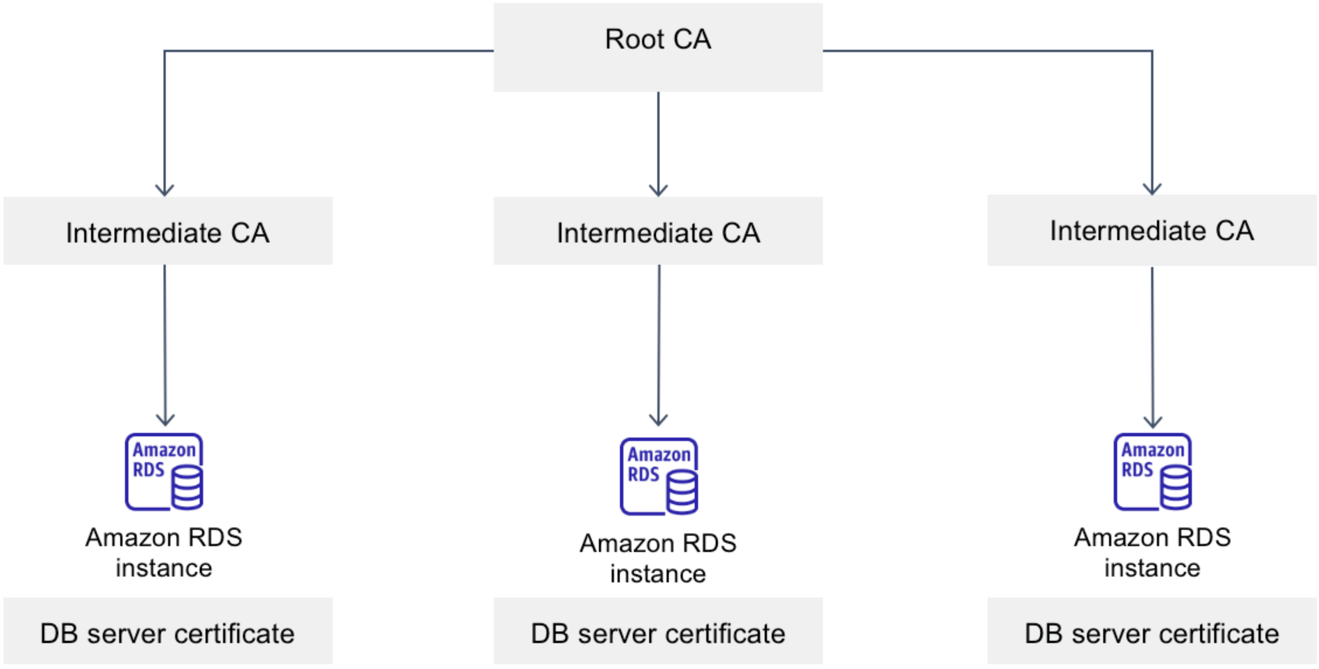
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see Certificate bundles for all AWS Regions and Certificate bundles for specific AWS Regions.

   > **Note**
   >
   > All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   - Security with Amazon Aurora MySQL
   - Security with Amazon Aurora PostgreSQL

Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate,** which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.



Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description
rds-ca-2019	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.
rds-ca-rsa2048-g1	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions. In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm. This CA remains valid for longer than the rds-ca-20 19 CA. This CA supports automatic server certificate rotation.
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.

Note

If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using describe-certificates.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the

DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

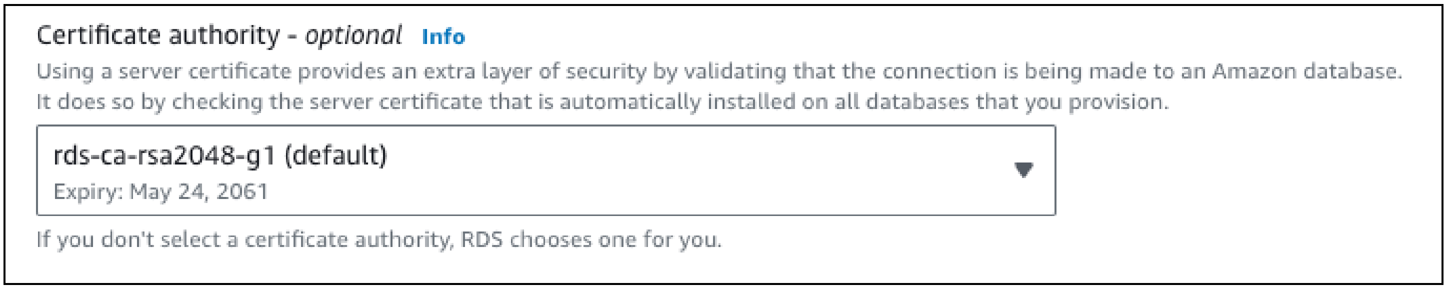
Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create an Aurora DB cluster – You can set the CA for a DB instance in an Aurora cluster when you create the first DB instance in the DB cluster using the AWS CLI or RDS API. Currently, you can't set the CA for the DB instances in a DB cluster when you create the DB cluster using the RDS console. For instructions, see Creating an Amazon Aurora DB cluster.
- Modify a DB instance – You can set the CA for a DB instance in a DB cluster by modifying it. For instructions, see Modifying a DB instance in a DB cluster.

> **Note**
>
> The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your AWS account by using the modify-certificates command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.



Certificate authority - *optional* Info

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1 (default)
Expiry: May 24, 2061

If you don't select a certificate authority, RDS chooses one for you.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the AWS CLI, you can set the CA for a DB instance using the create-db-instance or modify-db-instance command.

If you're using the AWS CLI, you can see the available CAs for your account by using the describe-certificates command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "MajorEngineVersion": "13",
            "EngineVersion": "13.4",
            "DBParameterGroupFamily": "postgres13",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": true,
            "SupportedFeatureNames": [
                "Lambda"
            ],
            "Status": "available",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "SupportsBabelfish": false,
            "SupportsCertificateRotationWithoutRestart": true,
            "SupportedCACertificateIdentifiers": [
                "rds-ca-2019",
                "rds-ca-rsa2048-g1",
                "rds-ca-ecc384-g1",
                "rds-ca-rsa4096-g1"
            ]
        }
    ]
}
```

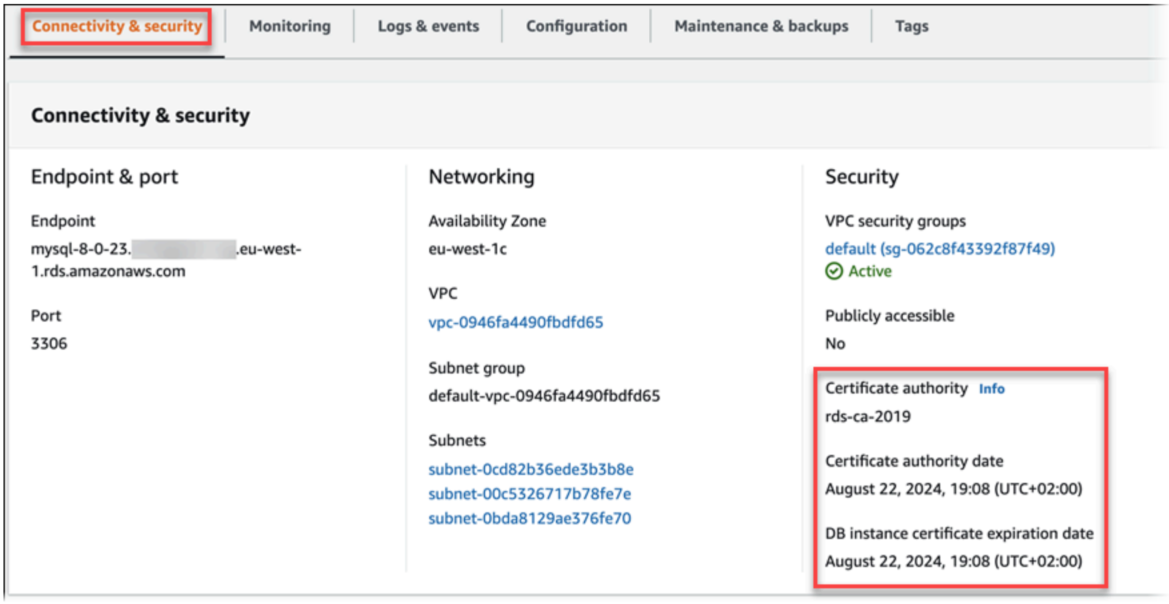
DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see Automatic server certificate rotation.

Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.



Connectivity & security

Certificate authority Info
rds-ca-2019

Certificate authority date
August 22, 2024, 19:08 (UTC+02:00)

DB instance certificate expiration date
August 22, 2024, 19:08 (UTC+02:00)

If you're using the AWS CLI, you can view the details about the CA for a DB instance by using the describe-db-instances command.

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

Certificate bundles for all AWS Regions

To get a certificate bundle for all AWS Regions, download it from https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem.

The bundle contains both the `rds-ca-2019` intermediate and root certificates. The bundle also contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle from https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b.

> **Note**
>
> Amazon RDS Proxy and Aurora Serverless v1 use certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy.
> If you're using Aurora Serverless v1, downloading Amazon RDS certificates isn't required. For more information, see Using TLS/SSL with Aurora Serverless v1.

Certificate bundles for specific AWS Regions

The bundle contains both the `rds-ca-2019` intermediate and root certificates. The bundle also contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

To get a certificate bundle for an AWS Region, download it from the link for the AWS Region in the following table.

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
US East (N. Virginia)	us-east-1-bundle.pem	us-east-1-bundle.p7b
US East (Ohio)	us-east-2-bundle.pem	us-east-2-bundle.p7b
US West (N. California)	us-west-1-bundle.pem	us-west-1-bundle.p7b
US West (Oregon)	us-west-2-bundle.pem	us-west-2-bundle.p7b
Africa (Cape Town)	af-south-1-bundle.pem	af-south-1-bundle.p7b
Asia Pacific (Hong Kong)	ap-east-1-bundle.pem	ap-east-1-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Asia Pacific (Hyderabad)	ap-south-2-bundle.pem	ap-south-2-bundle.p7b
Asia Pacific (Jakarta)	ap-southeast-3-bundle.pem	ap-southeast-3-bundle.p7b
Asia Pacific (Melbourne)	ap-southeast-4-bundle.pem	ap-southeast-4-bundle.p7b
Asia Pacific (Mumbai)	ap-south-1-bundle.pem	ap-south-1-bundle.p7b
Asia Pacific (Osaka)	ap-northeast-3-bundle.pem	ap-northeast-3-bundle.p7b
Asia Pacific (Tokyo)	ap-northeast-1-bundle.pem	ap-northeast-1-bundle.p7b
Asia Pacific (Seoul)	ap-northeast-2-bundle.pem	ap-northeast-2-bundle.p7b
Asia Pacific (Singapore)	ap-southeast-1-bundle.pem	ap-southeast-1-bundle.p7b
Asia Pacific (Sydney)	ap-southeast-2-bundle.pem	ap-southeast-2-bundle.p7b
Canada (Central)	ca-central-1-bundle.pem	ca-central-1-bundle.p7b
Canada West (Calgary)	ca-west-1-bundle.pem	ca-west-1-bundle.p7b
Europe (Frankfurt)	eu-central-1-bundle.pem	eu-central-1-bundle.p7b
Europe (Ireland)	eu-west-1-bundle.pem	eu-west-1-bundle.p7b
Europe (London)	eu-west-2-bundle.pem	eu-west-2-bundle.p7b
Europe (Milan)	eu-south-1-bundle.pem	eu-south-1-bundle.p7b
Europe (Paris)	eu-west-3-bundle.pem	eu-west-3-bundle.p7b
Europe (Spain)	eu-south-2-bundle.pem	eu-south-2-bundle.p7b
Europe (Stockholm)	eu-north-1-bundle.pem	eu-north-1-bundle.p7b
Europe (Zurich)	eu-central-2-bundle.pem	eu-central-2-bundle.p7b
Israel (Tel Aviv)	il-central-1-bundle.pem	il-central-1-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Middle East (Bahrain)	me-south-1-bundle.pem	me-south-1-bundle.p7b
Middle East (UAE)	me-central-1-bundle.pem	me-central-1-bundle.p7b
South America (São Paulo)	sa-east-1-bundle.pem	sa-east-1-bundle.p7b

AWS GovCloud (US) certificates

To get a certificate bundle that contains both the intermediate and root certificates for the AWS GovCloud (US) Regions, download from https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.pem.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle from https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b.

The bundle contains both the `rds-ca-2019` intermediate and root certificates. The bundle also contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

To get a certificate bundle for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

AWS GovCloud (US) Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
AWS GovCloud (US-East)	us-gov-east-1-bundle.pem	us-gov-east-1-bundle.p7b
AWS GovCloud (US-West)	us-gov-west-1-bundle.pem	us-gov-west-1-bundle.p7b

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates rds-ca-2019 are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances , consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB cluster.

> **Note**
>
> Amazon RDS Proxy and Aurora Serverless v1 use certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy.
> If you're using Aurora Serverless v1, downloading Amazon RDS certificates isn't required. For more information, see Using TLS/SSL with Aurora Serverless v1.

> **Note**
>
> If you're using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 depending on your engine. Run the `modify-db-instance` command , using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.
> If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics

- Updating your CA certificate by modifying your DB instance
- Updating your CA certificate by applying maintenance
- Automatic server certificate rotation

- Sample script for importing certificates into your trust store

Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from *rds-ca-2019* to *rds-ca-rsa2048-g1*. You can choose a different certificate. For more information, see Certificate authorities.

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see Automatic server certificate rotation.

To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB cluster.
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   - Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates
   - Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store.

   > **Note**
   >
   > The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the `SupportsCertificateRotationWithoutRestart` flag.

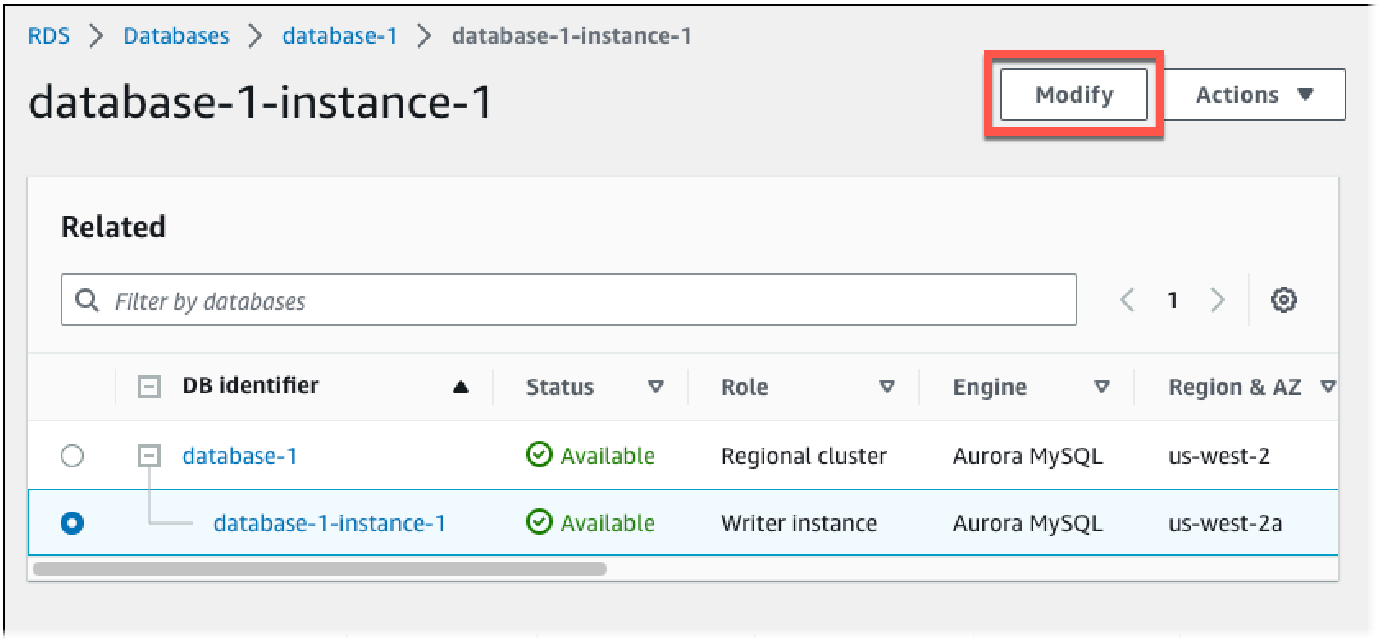
   > **Note**
   >
   > Reboot your Babelfish cluster after modifying to update the CA certificate.

   > **Important**
   >
   > If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.
   > To set an override for your cluster CA that's different from the default RDS CA, use the modify-certificates CLI command.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance .

Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

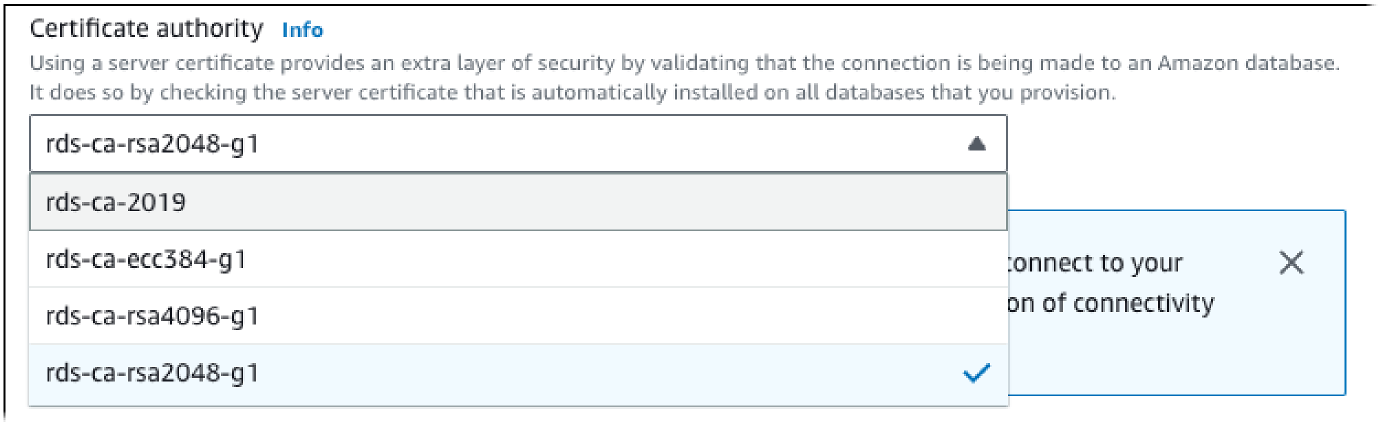


database-1-instance-1

Related

	DB identifier	Status	Role	Engine	Region & AZ
○	database-1	Available	Regional cluster	Aurora MySQL	us-west-2
●	database-1-instance-1	Available	Writer instance	Aurora MySQL	us-west-2a

4. In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.



Certificate authority

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

5. Choose **Continue** and check the summary of modifications.

6. To apply the changes immediately, choose **Apply immediately**.

7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To use the AWS CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance , call the modify-db-instance or modify-db-cluster command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

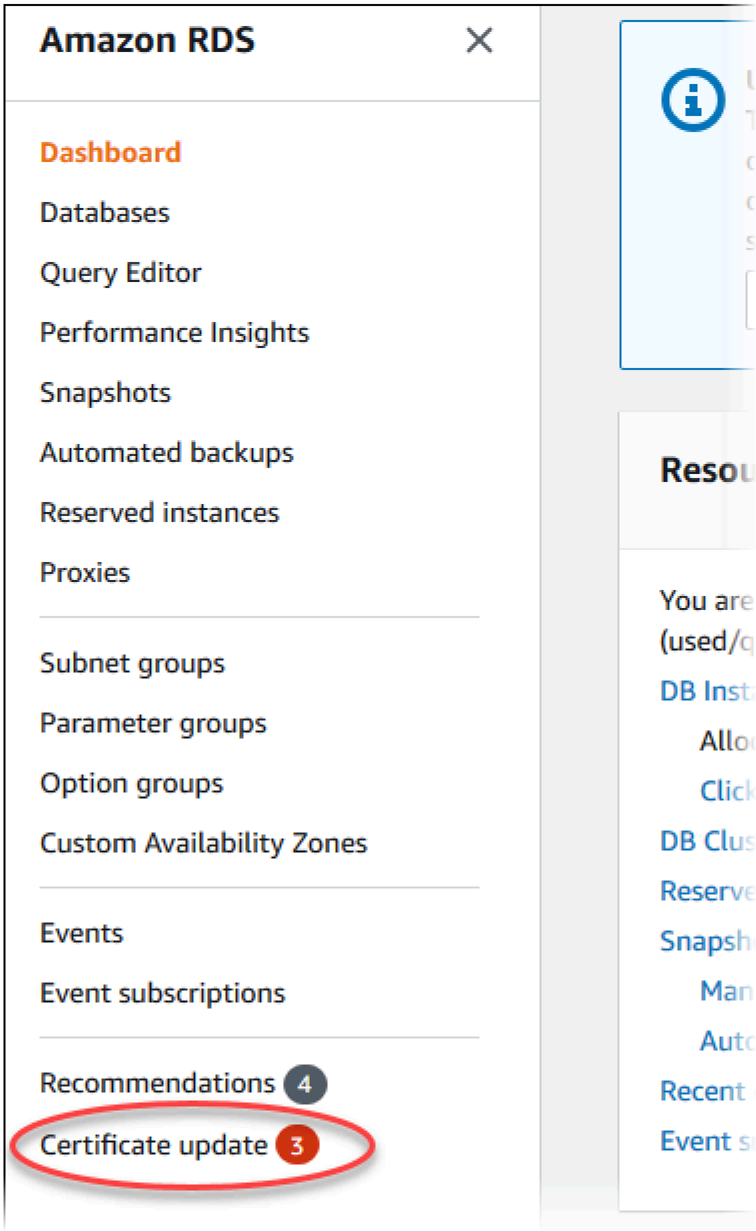
> **Note**
>
> If your instance requires reboot, you can use the modify-db-instance CLI command and specify the `--no-certificate-rotation-restart` option.

Updating your CA certificate by applying maintenance

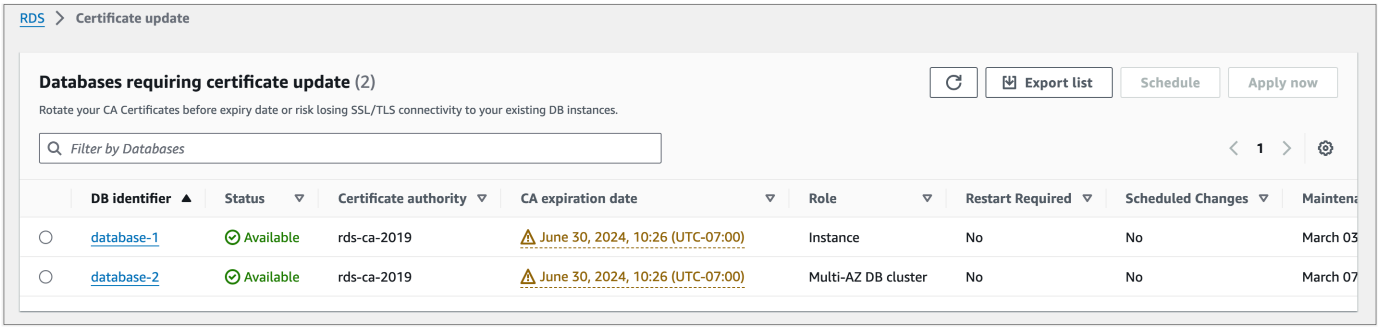
Perform the following steps to update your CA certificate by applying maintenance.

To update your CA certificate by applying maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Certificate update**.



The **Databases requiring certificate update** page appears.



Databases requiring certificate update (2)

Rotate your CA Certificates before expiry date or risk losing SSL/TLS connectivity to your existing DB instances.

	DB identifier ▲	Status	Certificate authority	CA expiration date	Role	Restart Required	Scheduled Changes	Maintena
○	database-1	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Instance	No	No	March 03
○	database-2	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Multi-AZ DB cluster	No	No	March 07

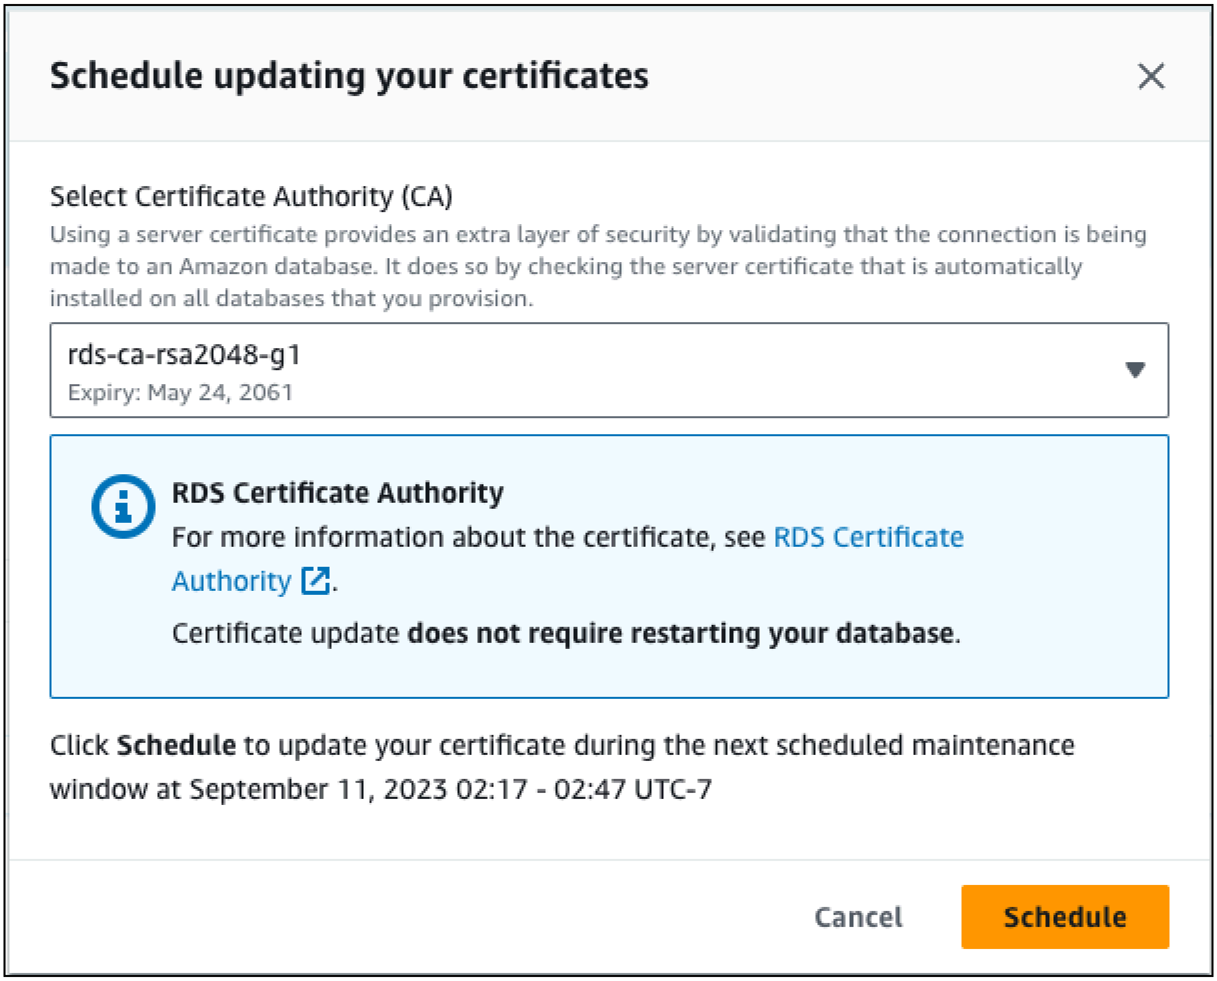
> **Note**
>
> This page only shows the DB instances for the current AWS Region. If you have databases in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance that you want to update.

   You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

> **Important**
>
> If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.



Schedule updating your certificates

Select Certificate Authority (CA)

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1
Expiry: May 24, 2061

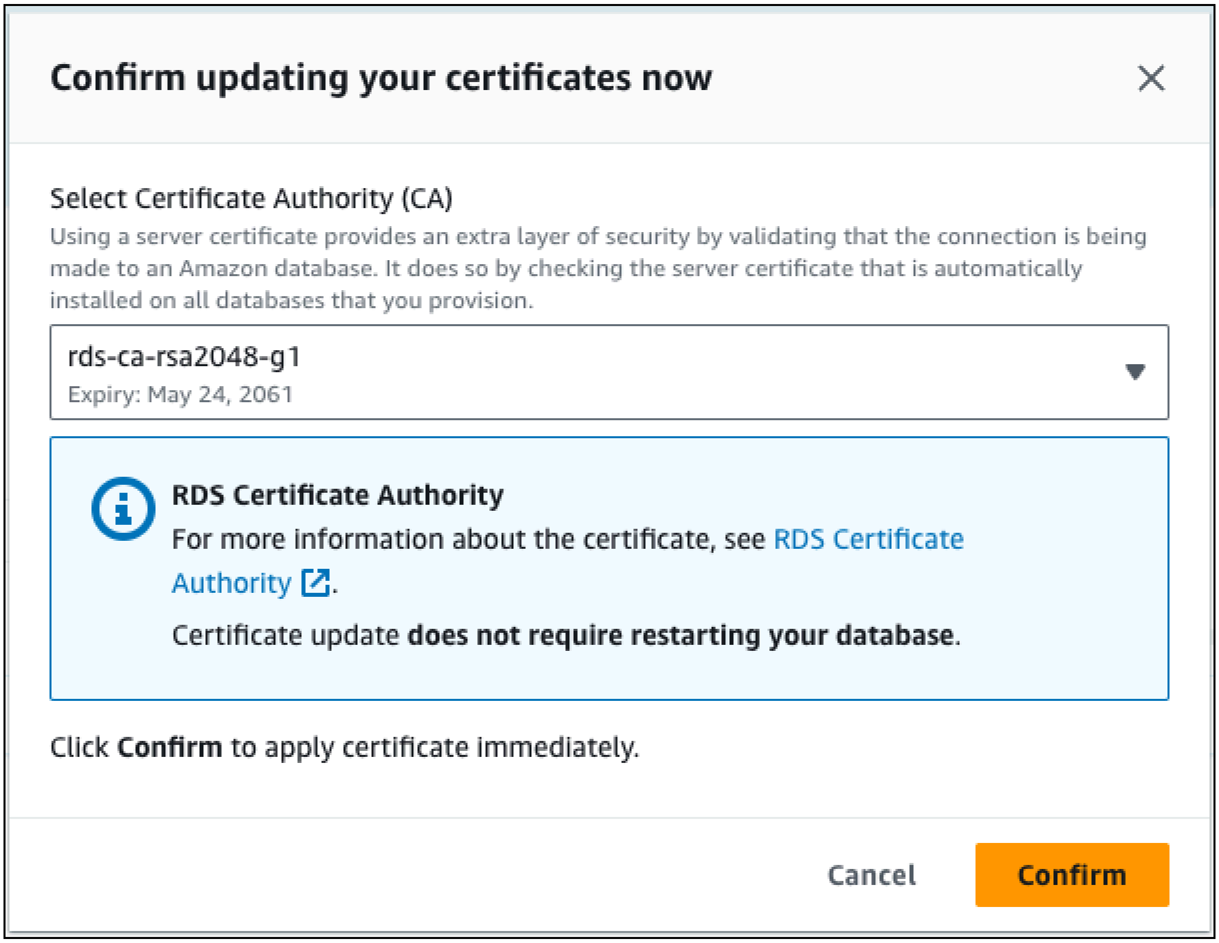
RDS Certificate Authority

For more information about the certificate, see RDS Certificate Authority.

Certificate update **does not require restarting your database**.

Click **Schedule** to update your certificate during the next scheduled maintenance window at September 11, 2023 02:17 - 02:47 UTC-7

b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.



Confirm updating your certificates now

Select Certificate Authority (CA)

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1
Expiry: May 24, 2061

RDS Certificate Authority

For more information about the certificate, see RDS Certificate Authority.

Certificate update **does not require restarting your database**.

Click **Confirm** to apply certificate immediately.

> **Important**
>
> Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance that you want to update.

Automatic server certificate rotation

If your CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities.

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database.

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Topics

Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
```

```
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
 ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}
{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
 s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore
 ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut
 -d " " -f3- | while read alias
do
   expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias
 "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
```

```
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
 ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
 s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore
 ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut
 -d " " -f3- | while read alias
do
   expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias
 "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?

- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon Aurora through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Identity and access management for Amazon Aurora

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

Service user – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see Troubleshooting Amazon Aurora identity and access.

Service administrator – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see How Amazon Aurora works with IAM.

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon Aurora.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the *AWS IAM Identity Center User Guide* and Using multi-factor authentication (MFA) in AWS in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account.

We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the *IAM User Guide*.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the *IAM User Guide*.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see IAM database authentication.

IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the *AWS IAM Identity Center User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the

principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

  - **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.
  - **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password.

To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon Aurora, see AWS managed policies for Amazon RDS.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon Aurora works with IAM

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

IAM features you can use with Amazon Aurora

IAM feature	Amazon Aurora support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes

IAM feature	Amazon Aurora support
ACLs	No
Attribute-based access control (ABAC) (tags in policies)	Yes
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how Amazon Aurora and other AWS services work with IAM, see AWS services that work with IAM in the *IAM User Guide*.

Topics

- Aurora identity-based policies
- Resource-based policies within Aurora
- Policy actions for Aurora
- Policy resources for Aurora
- Policy condition keys for Aurora
- Access control lists (ACLs) in Aurora
- Attribute-based access control (ABAC) in policies with Aurora tags
- Using temporary credentials with Aurora
- Forward access sessions for Aurora
- Service roles for Aurora
- Service-linked roles for Aurora

Aurora identity-based policies

Supports identity-based policies	Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see Identity-based policy examples for Amazon Aurora.

Resource-based policies within Aurora

Supports resource-based policies	No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Aurora

Supports policy actions	Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
      "rds:action1",
      "rds:action2"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Policy resources for Aurora

Supports policy resources	Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the `dbtest` DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
      "resource1",
      "resource2"
```

To see a list of Aurora resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

Policy condition keys for Aurora

Supports service-specific policy condition keys	Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see [Condition Keys for Amazon RDS]() in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS]().

Access control lists (ACLs) in Aurora

Supports access control lists (ACLs)	No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Aurora tags

Supports attribute-based access control (ABAC) tags in policies	Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element]() of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see What is ABAC? in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

For more information about tagging Aurora resources, see Specifying conditions: Using custom tags. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values.

Using temporary credentials with Aurora

Supports temporary credentials	Yes

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Forward access sessions for Aurora

Supports forward access sessions	Yes

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Aurora

Supports service roles	Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> ⚠ **Warning**
>
> Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

Service-linked roles for Aurora

Supports service-linked roles	Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see Using service-linked roles for Amazon Aurora.

Identity-based policy examples for Amazon Aurora

By default, permission sets and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the *IAM User Guide*.

Topics

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.

- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following AWS managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCreateDBInstanceOnly",
         "Effect": "Allow",
         "Action": [
            "rds:CreateDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:db:test*",
            "arn:aws:rds:*:123456789012:og:default*",
            "arn:aws:rds:*:123456789012:pg:default*",
            "arn:aws:rds:*:123456789012:subgrp:default"
         ],
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql",
               "rds:DatabaseClass": "db.t2.micro"
            }
         }
      }
   ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the user to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).
- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (* indicates any region in this example), the AWS account number (123456789012 is the account number in this example),

  and the type of resource. For more information about creating ARNs, see [Working with Amazon Resource Names (ARNs) in Amazon RDS]().

  The `Resource` element in the example specifies the following policy constraints on resources for the user:

  - The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
  - The option group for the new DB instance must begin with `default`.
  - The DB parameter group for the new DB instance must begin with `default`.
  - The subnet group for the new DB instance must be the `default` subnet group.

- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see [Policy condition keys for Aurora](). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the `Engine` parameter in [CreateDBInstance](). For information about the valid condition values for `rds:DatabaseClass`, see [Supported DB engines for DB instance classes]().

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see [Actions Defined by Amazon RDS]() in the *Service Authorization Reference*.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in [Managing access using policies]().

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root AWS account:

```
AmazonRDSFullAccess
```

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the `Resource` element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": [
            "arn:aws:rds:*:*:pg:mydbpg",
            "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
         ]
      }
   ]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:pg:*",
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
         ]
      },
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
         "Resource": "arn:aws:rds:us-west-2:123456789012:db:my-mysql-instance"
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
         "Resource": "arn:aws:rds:us-east-1:123456789012:db:mydb"
      }
   ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowMySQLCreate",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql"
            },
            "Bool": {
               "rds:MultiAz": false
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyLargeCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseClass": [
                  "db.r3.8xlarge",
                  "db.m4.10xlarge"
               ]
            }
         }
      },
      {
         "Sid": "DenyPIOPSCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "NumericNotEquals": {
               "rds:Piops": "0"
            }
         }
      }
   ]
}
```

Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource": "*",
         "Condition": {
            "streq": {
               "rds:req-tag/stage": [
                  "test",
                  "qa",
                  "production"
               ]
            }
         }
      }
   ]
}
```

Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

> **Note**
>
> Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
`db-tag`	DB instances, including read replicas
`snapshot-tag`	DB snapshots
`ri-tag`	Reserved DB instances
`og-tag`	DB option groups
`pg-tag`	DB parameter groups
`subgrp-tag`	DB subnet groups

RDS tag identifier	Applies to
`es-tag`	Event subscriptions
`cluster-tag`	DB clusters
`cluster-pg-tag`	DB cluster parameter groups
`cluster-snapshot-tag`	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":
["value"]} }
```

For example, the following `Condition` element applies to DB instances with a tag named `environment` and a tag value of `production`.

```
"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }
```

For information about creating tags, see Tagging Amazon RDS resources.

Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the `AddTagsToResource` and `RemoveTagsFromResource` actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyTagUpdates",
         "Effect":"Deny",
         "Action":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"*"
      }
   ]
}
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":" [
            "arn:aws:rds:*:123456789012:pg:*",
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
         ]
      },
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyProductionCreate",
         "Effect":"Deny",
         "Action":"rds:CreateDBInstance",
         "Resource":"arn:aws:rds:*:123456789012:pg:*",
         "Condition":{
            "StringEquals":{
               "rds:pg-tag/usage":"prod"
            }
         }
      }
   ]
}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
         "Condition":{
            "StringEqualsIfExists":{
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```

AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the *IAM User Guide*.

Topics

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `outposts` – Allows principals to get AWS Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.

- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (`dbqms`) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

Permissions details

This policy includes the following permission:

- `ds` – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon Aurora.

Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added a new permission to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role to allow RDS Custom for SQL Server to modify the underlying database host instance type. RDS also added the `ec2:DescribeInstanceTypes` permission to get instance type information for database host. For more information, see AWS managed policies for Amazon RDS.	April 8, 2024
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSCustom InstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see AWS	February 27, 2024

Change	Description	Date
	managed policies for Amazon RDS.	
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new statement IDs to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see Service-linked role permissions for Amazon Aurora.	January 19, 2024
AWS managed policies for Amazon RDS – Update to existing policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see AWS managed policy: AmazonRDSPerformanceInsightsReadOnly and AWS managed policy: AmazonRDSPerformanceInsightsFullAccess	October 23, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added new permissions to `AmazonRDSFullAccess` managed policy. The permissions allow you to generate, view, and delete the performance analysis report for a time period. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 17, 2023
AWS managed policies for Amazon RDS – New policy and update to existing policy	Amazon RDS added new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and a new managed policy named `AmazonRDSPerformanceInsightsFullAccess` . These permissions allow you to analyse the Performance Insights for a time period, view the analysis results along with the recommendations, and delete the reports. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 16, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace `ListMetrics` to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` . This namespace is required for Amazon RDS to list specific resource usage metrics. For more information, see Overview of managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.	April 4, 2023

Change	Description	Date
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role for integration with AWS Secrets Manager. RDS requires integration with Secrets Manager for managing master user passwords in Secrets Manager. The secret uses a reserved naming convention and restricts customer updates. For more information, see Password management with Amazon Aurora and AWS Secrets Manager.	December 22, 2022

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policies	Amazon RDS added a new permission to the `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` managed policies to allow you to turn on Amazon DevOps Guru in the RDS console. This permission is required to check whether DevOps Guru is turned on. For more information, see Configuring IAM access policies for DevOps Guru for RDS.	December 19, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSPreviewServiceRolePolicy` for `PutMetricData` . This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022

Change	Description	Date
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSBetaServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AWSServiceRoleForRDS` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	April 22, 2022

Change	Description	Date
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSPerformanceInsightsReadOnly` to allow Amazon RDS to call AWS services on behalf of your DB instances. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	March 10, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new Amazon CloudWatch namespaces to `AWSServiceRoleForRDS` for `PutMetricData` . These namespaces are required for Amazon DocumentDB (with MongoDB compatibility) and Amazon Neptune to publish CloudWatch metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	March 4, 2022
Amazon RDS started tracking changes	Amazon RDS started tracking changes for its AWS managed policies.	October 26, 2021

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- Granting permissions to publish notifications to an Amazon SNS topic
- Setting up access to an Amazon S3 bucket (PostgreSQL import)
- Setting up access to an Amazon S3 bucket (PostgreSQL export)

IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see Using SSL/TLS to encrypt a connection to a DB cluster.
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (AWS) JDBC Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) JDBC Driver GitHub repository.

The Amazon Web Services (AWS) Python Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) Python Driver GitHub repository.

Topics

- CLI and SDK support
- Limitations for IAM database authentication
- Recommendations for IAM database authentication
- Unsupported AWS global condition context keys
- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Connecting to your DB cluster using IAM authentication

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and IAM database authentication, see Supported Regions and Aurora DB engines for IAM database authentication.

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see Supported DB engines for DB instance classes.

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:

- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- IAM database authentication throttles connections in the following scenarios:
  - You exceed 20 connections per second using authentication tokens each signed by a different IAM identity.
  - You exceed 200 connections per second using different authentication tokens.

  Connections that use the same authentication token are not throttled. We recommend that you reuse authentication tokens when possible.
- Currently, IAM database authentication doesn't support all global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.
- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For Aurora PostgreSQL, you cannot use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

  The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See RDS Proxy pricing.

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see AWS global condition context keys in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see Creating an Amazon Aurora DB cluster.
- To modify a DB cluster to enable IAM database authentication, see Modifying an Amazon Aurora DB cluster.
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see Restoring from a DB cluster snapshot.
- To restore a DB cluster to a point in time with IAM database authentication enabled, see Restoring a DB cluster to a specified time.

Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to modify.

> **Note**
>
> You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify cluster**.

AWS CLI

To create a new DB cluster with IAM authentication by using the AWS CLI, use the `create-db-cluster` command. Specify the `--enable-iam-database-authentication` option.

To update an existing DB cluster to have or not have IAM authentication, use the AWS CLI command `modify-db-cluster`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

> **Note**
>
> You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

If you are restoring a DB cluster, use one of the following AWS CLI commands:

- `restore-db-cluster-to-point-in-time`
- `restore-db-cluster-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation `ModifyDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

If you are restoring a DB cluster, use one of the following API operations:

- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

Note

To learn more about IAM policies, see Identity and access management for Amazon Aurora.

The following example policy allows a user to connect to a DB cluster using IAM database authentication.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:1234567890:dbuser:cluster-ABCDEFGHIJKL01234/
db_user"
```

```
            ]
        }
    ]
}
```

Important

A user with administrator permissions can access DB clusters without explicit permissions in an IAM policy. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- `Effect` – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- `Action` – Specify `rds-db:connect` to allow connections to the DB cluster.
- `Resource` – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

  ```
  arn:aws:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
  ```

  In this format, replace the following:

  - *`region`* is the AWS Region for the DB cluster. In the example policy, the AWS Region is `us-east-2`.

- *account-id* is the AWS account number for the DB cluster. In the example policy, the account number is 1234567890. The user must be in the same account as the account for the DB cluster.

  To perform cross-account access, create an IAM role with the policy shown above in the account for the DB cluster and allow your other account to assume the role.
- *DbClusterResourceId* is the identifier for the DB cluster. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is cluster-ABCDEFGHIJKL01234.

  To find a DB cluster resource ID in the AWS Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

  Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB cluster in the current AWS Region, as shown following.

  ```
  aws rds describe-db-clusters --query "DBClusters[*].
  [DBClusterIdentifier,DbClusterResourceId]"
  ```

  > **Note**
  >
  > If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as prx-ABCDEFGHIJKL01234. For information about using IAM database authentication with RDS Proxy, see Connecting to a proxy using IAM authentication.
- *db-user-name* is the name of the database account to associate with IAM authentication. In the example policy, the database account is db_user.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

```
{
   "Version": "2012-10-17",
   "Statement": [
```

```
       {
          "Effect": "Allow",
          "Action": [
              "rds-db:connect"
          ],
          "Resource": [
              "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-ABCDEFGHIJKL01234/
jane_doe",
              "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-ABCDEFGHIJKL01234/
mary_roe"
          ]
       }
    ]
}
```

The following policy uses the "*" character to match all DB clusters and database accounts for a particular AWS account and AWS Region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:1234567890:dbuser:*/*"
            ]
        }
    ]
}
```

The following policy matches all of the DB clusters for a particular AWS account and AWS Region. However, the policy only grants access to DB clusters that have a `jane_doe` database account.

```
{
   "Version": "2012-10-17",
    "Statement": [
       {
          "Effect": "Allow",
          "Action": [
              "rds-db:connect"
          ],
          "Resource": [
              "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
          ]
       }
    ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named *dev*, and another database named *test*. If the database user `jane_doe` has access only to *dev*, any users or roles that access that DB cluster with the `jane_doe` user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon Aurora.

Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

> **Note**
>
> You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/
jane_doe
```

If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB cluster using the `jane_doe` database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

Note

The user name used for IAM authentication must match the case of the user name in the database.

Topics

- Using IAM authentication with Aurora MySQL
- Using IAM authentication with Aurora PostgreSQL

Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows Aurora MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for

IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

> **Note**
>
> If you see the following message, it means that the AWS-provided plugin is not available for the current DB cluster.
> `ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded`
> To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see Region and version availability and Enabling and disabling IAM database authentication.

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with Aurora PostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access. You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the `rds_ad` role. This also applies to nested memberships. For more information, see Step 7: Create PostgreSQL users for your Kerberos principals .

Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the *AWS General Reference.*) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Topics

- Connecting to your DB cluster using IAM authentication with the AWS drivers
- Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client
- Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client
- Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Go
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Java
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3)

Connecting to your DB cluster using IAM authentication with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the AWS drivers, see the corresponding language driver for your Aurora MySQL or Aurora PostgreSQL DB cluster.

Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the AWS CLI and `mysql` command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token
- Connecting to a DB cluster

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The AWS Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

  For more information, see Using TLS with Aurora MySQL DB clusters.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.
- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

  If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.
- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```

RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
```

```
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
| Variable_name | Value

                                                                         |
+---------------+-------------+
| ...           | ...
| Ssl_cipher    | AES256-SHA

                                                                         |
| ...           | ...
| Ssl_version   | TLSv1.1

                                                                         |
| ...           | ...
+-----------------------------+
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the AWS CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token
- Connecting to an Aurora PostgreSQL cluster

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The AWS Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to an Aurora PostgreSQL cluster

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
 sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName
 password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB cluster (cluster endpoint) that you want to access
- `port` – The port number used for connecting to your DB cluster
- `sslmode` – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `sslrootcert` – The full path to the SSL certificate file that contains the public key

  For more information, see Securing Aurora PostgreSQL data with SSL/TLS.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.
- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

> **Note**
>
> You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for .NET as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK.CORE and the AWSSDK.RDS packages are required. To connect to a DB cluster, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to an Aurora MySQL DB cluster. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB cluster that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB cluster
- `SslMode` – The SSL mode to use

  When you use `SslMode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `SslCa` – The full path to the SSL certificate for Amazon Aurora

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
  class Program
  {
    static void Main(string[] args)
    {
      var pwd =
 Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
 "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
```

```
      // for debug only Console.Write("{0}\n", pwd);  //this verifies the token is
 generated

      MySqlConnection conn = new
 MySqlConnection($"server=mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
      conn.Open();

      // Define a query
      MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

      // Execute a query
      MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

      // Read all rows and output the first column in each row
      while (mysqlDataRdr.Read())
        Console.WriteLine(mysqlDataRdr[0]);

      mysqlDataRdr.Close();
      // Close connection
      conn.Close();
    }
  }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB cluster that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB cluster
- `SSL Mode` – The SSL mode to use

  When you use `SSL Mode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `Root Certificate` – The full path to the SSL certificate for Amazon Aurora

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
 RDSAuthTokenGenerator.GenerateAuthToken("postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com", 5432, "jane_doe");
// for debug only Console.Write("{0}\n", pwd);  //this verifies the token is generated

            NpgsqlConnection conn = new
 NpgsqlConnection($"Server=postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL
 Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
                   NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
 pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.Write("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
}
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB cluster using IAM authentication and the AWS SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB cluster that you want to access

> **Note**
>
> You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB cluster
- `region` – The AWS Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

`creds := credentials.NewEnvCredentials()`

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

`sess := session.Must(session.NewSession())`

`creds := sess.Config.Credentials`

If you make this change, make sure you add the following import:

`"github.com/aws/aws-sdk-go/aws/session"`

- Connecting using IAM authentication and the AWS SDK for Go V1.

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```
package main

import (
     "context"
     "database/sql"
     "fmt"

     "github.com/aws/aws-sdk-go-v2/config"
     "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
     _ "github.com/go-sql-driver/mysql"
)

func main() {
     var dbName string = "DatabaseName"
     var dbUser string = "DatabaseUser"
     var dbHost string = "mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com"
     var dbPort int = 3306
     var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
     var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
     panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
     context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
     panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB cluster using IAM authentication and the AWS SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Set up the AWS SDK for Java

For examples on how to use the SDK for Java 2.x, see Amazon RDS examples using SDK for Java 2.x.

Topics

- Generating an IAM authentication token
- Manually constructing an IAM authentication token
- Connecting to a DB cluster

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for users.

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

     String region = "us-west-2";
     String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
     String port = "3306";
     String username = "jane_doe";

     System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
 username) {

     RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
      .credentials(new DefaultAWSCredentialsProviderChain())
      .region(region)
      .build();

     String authToken = generator.getAuthToken(
      GetIamAuthTokenRequest.builder()
      .hostname(hostName)
      .port(Integer.parseInt(port))
      .userName(username)
      .build());

     return authToken;
    }

}
```

Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the *AWS General Reference.*

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
```

```
   public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
   public static String payload = StringUtils.EMPTY;
   public static String signedHeader = "host";
   public static String algorithm = "AWS4-HMAC-SHA256";

        }
    }
}
```

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon Aurora that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB cluster.) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.

- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB cluster that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB cluster.
  - REGION_NAME – The AWS Region where the DB cluster is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon Aurora that is specific to an AWS Region.

    To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB cluster. Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

Note

Specify a password for DEFAULT_KEY_STORE_PASSWORD other than the prompt shown here as a security best practice.

            KeyStore ks = KeyStore.getInstance(KEY_STORE_TYPE, KEY_STORE_PROVIDER);
            ks.load(null);
            ks.setCertificateEntry("rootCaCertificate", rootX509Certificate);
            ks.store(fos, DEFAULT_KEY_STORE_PASSWORD.toCharArray());
        }
        return keyStoreFile;
    }

    /**
     * This method clears the SSL properties.
     * @throws Exception
     */
    private static void clearSslProperties() throws Exception {
           System.clearProperty("javax.net.ssl.trustStore");
           System.clearProperty("javax.net.ssl.trustStoreType");
           System.clearProperty("javax.net.ssl.trustStorePassword");
    }

}
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- `ENDPOINT` – The endpoint of the DB cluster that you want to access
- `PORT` – The port number used for connecting to your DB cluster
- `USER` – The database account that you want to access
- `REGION` – The AWS Region where the DB cluster is running
- `DBNAME` – The database that you want to access
- `SSLCERTIFICATE` – The full path to the SSL certificate for Amazon Aurora

  For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

This code connects to an Aurora MySQL DB cluster.

Before running this code, install the PyMySQL driver by following the instructions in the Python Package Index.

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn =  pymysql.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT,
 database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
 password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication.

Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

Topics

- [I'm not authorized to perform an action in Aurora]
- [I'm not authorized to perform iam:PassRole]
- [I want to allow people outside of my AWS account to access my Aurora resources]

I'm not authorized to perform an action in Aurora

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a *`widget`* but does not have `rds:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *`my-example-widget`* resource using the `rds:`*`GetWidget`* action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Aurora.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I want to allow people outside of my AWS account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see How Amazon Aurora works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

Amazon CloudWatch Alarms

> Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon Aurora API calls in AWS CloudTrail.

Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora.

Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon Aurora log files.

Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see Viewing and responding to Amazon Aurora recommendations.

Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see Trusted Advisor best practices (checks).

Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see Monitoring Amazon Aurora with Database Activity Streams.

For more information about monitoring Aurora see Monitoring metrics in an Amazon Aurora cluster.

Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and compliance quick start guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- AWS compliance resources – This collection of workbooks and guides that might apply to your industry and location.
- AWS Config – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.

Resilience in Amazon Aurora

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see Backing up and restoring an Amazon Aurora DB cluster.

Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the

Availability Zones that a DB cluster spans within an AWS Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see Replication with Amazon Aurora.

Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see High availability for Amazon Aurora.

Infrastructure security in Amazon Aurora

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well‐Architected Framework*.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Aurora offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see Controlling access with security groups.

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see Hiding a DB cluster in a VPC from the internet.

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the *Amazon EC2 User Guide.*

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the *Amazon VPC User Guide*. For more information about RDS API operations, see Amazon RDS API Reference.

You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see Scenarios for accessing a DB cluster in a VPC.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
   "Statement":[
      {
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBInstance",
            "rds:ModifyDBInstance",
            "rds:CreateDBSnapshot"
         ],
         "Resource":"*"
      }
   ]
}
```

Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account `123456789012` all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
     }
   ]
}
```

Security best practices for Amazon Aurora

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources. Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual user for each person who manages Amazon Aurora resources, including yourself. Don't use AWS root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see Rotating your AWS Secrets Manager secrets in the *AWS Secrets Manager User Guide*. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

For more information about Amazon Aurora security, see Security in Amazon Aurora. For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.

AWS Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see Amazon Relational Database Service controls in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see What is AWS Security Hub?.

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes various data sources, including Amazon RDS login activity. It uses threat intelligence feeds and machine learning to identify unexpected, potentially unauthorized, suspicious login behavior, and malicious activity within your AWS environment.

When Amazon GuardDuty RDS Protection detects a potentially suspicious or anomalous login attempt that indicates a threat to your database, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see Monitoring threats with Amazon GuardDuty RDS Protection.

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the Amazon EC2 API or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

> **Note**
>
> In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see Security groups in the *Amazon Virtual Private Cloud User Guide*.

Note

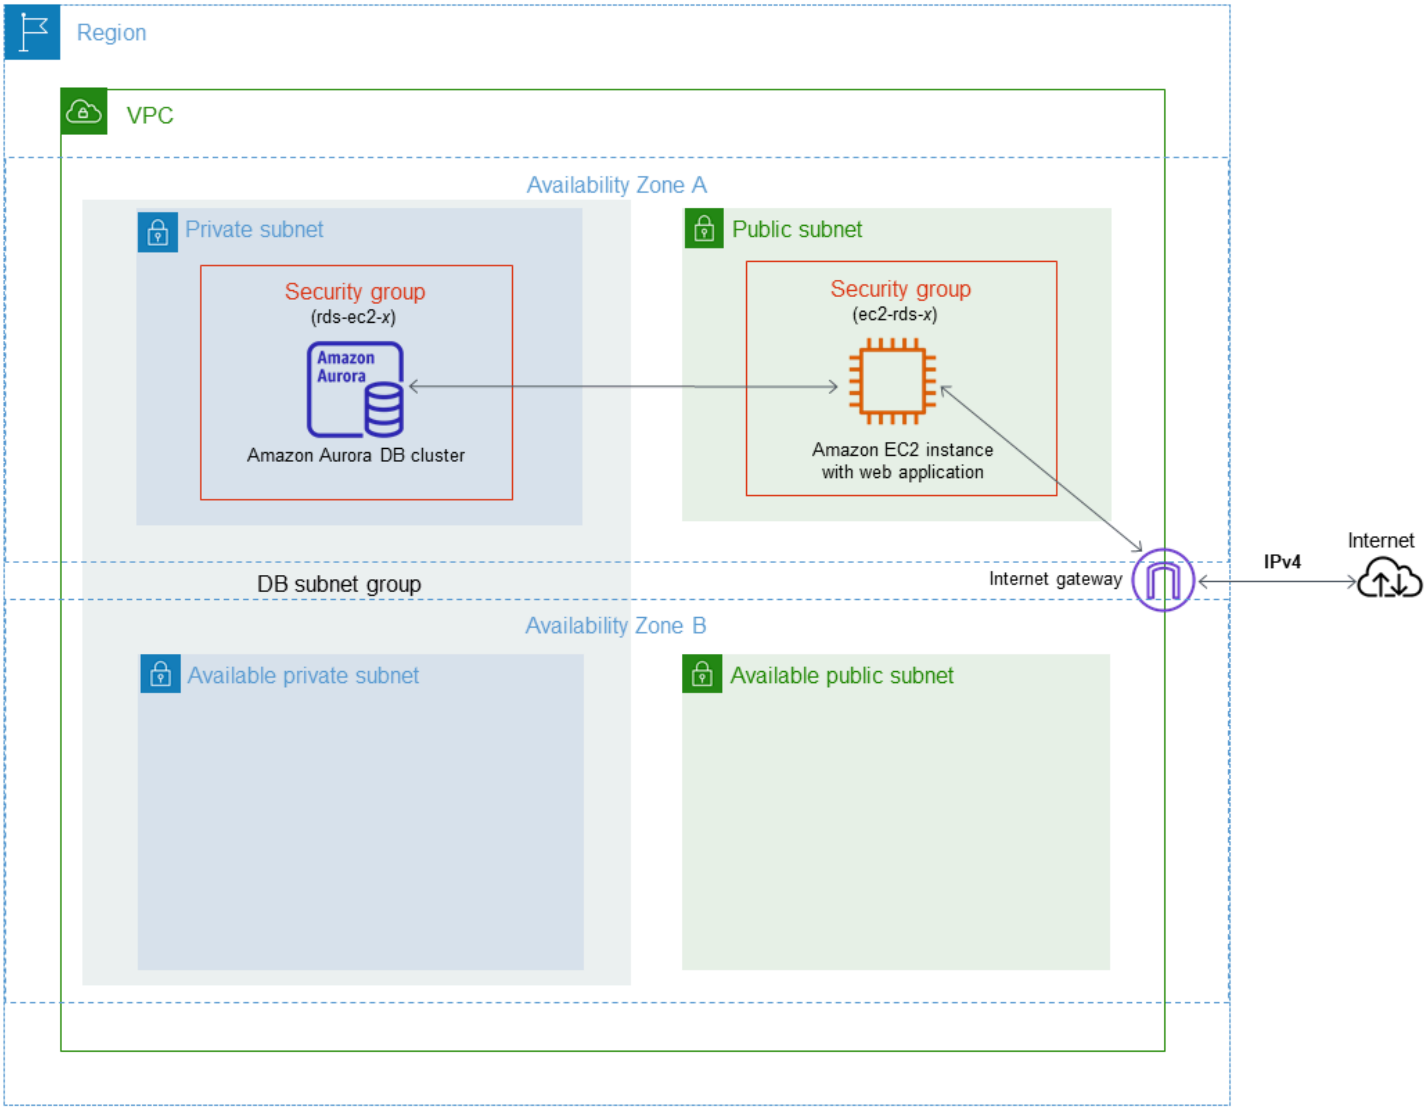
If your DB cluster is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB cluster and add the DB cluster to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.



For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only). For more information about using a VPC, see Amazon VPC VPCs and Amazon Aurora.

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to the DB cluster in the VPC by creating a security group and Security groups in the *Amazon Virtual Private Cloud User Guide*.

Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using **Modify cluster** on the RDS console, the `ModifyDBCluster` Amazon RDS API, or the `modify-db-cluster` AWS CLI command.

The following CLI example associates a specific VPC group and removes DB security groups from the DB cluster

```
aws rds modify-db-cluster --db-cluster-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

⚠ **Important**

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

ⓘ **Note**

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
Aurora MySQL	Version 2: ALTER, ALTER ROUTINE, CREATE, CREATE ROUTINE, CREATE TEMPORARY TABLES, CREATE USER, CREATE VIEW, DELETE, DROP, EVENT, EXECUTE, GRANT OPTION, INDEX, INSERT, LOAD FROM S3, LOCK TABLES, PROCESS, REFERENCES, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SELECT, SELECT INTO S3, SHOW DATABASES, SHOW VIEW, TRIGGER, UPDATE	—
	Version 3: ALTER, APPLICATION_PASSWORD_ADMIN, ALTER ROUTINE, CONNECTION_ADMIN, CREATE, CREATE ROLE, CREATE ROUTINE, CREATE TEMPORARY TABLES, CREATE USER, CREATE VIEW, DELETE, DROP, DROP ROLE, EVENT, EXECUTE, INDEX, INSERT, LOCK TABLES, PROCESS, REFERENCES, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, ROLE_ADMIN, SET_USER_ID, SELECT, SHOW DATABASES, SHOW_ROUTINE (Aurora MySQL version 3.04 and higher), SHOW VIEW, TRIGGER, UPDATE, XA_RECOVER_ADMIN	rds_superuser_role For more information about rds_superuser_role, see Role-based privilege model.
Aurora PostgreSQL	LOGIN, NOSUPERUSER, INHERIT, CREATEDB, CREATEROLE, NOREPLICATION, VALID UNTIL 'infinity'	RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions.

Using service-linked roles for Amazon Aurora

Amazon Aurora uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB clusters.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account. The role permissions policy allows Amazon Aurora to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

Important

If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether Amazon Aurora is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete *all* of your DB clusters.

Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

To delete a cluster (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the **Databases** list, choose the cluster that you want to delete.
3. For **Cluster Actions**, choose **Delete**.
4. Choose **Delete**.

To delete a cluster (CLI)

See `delete-db-cluster` in the *AWS CLI Command Reference*.

To delete a cluster (API)

See `DeleteDBCluster` in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Amazon VPC VPCs and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

Topics

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB cluster in a VPC

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC , see Scenarios for accessing a DB cluster in a VPC.

Topics

- Working with a DB cluster in a VPC
- Working with DB subnet groups
- Shared subnets
- Amazon Aurora IP addressing
- Hiding a DB cluster in a VPC from the internet
- Creating a DB cluster in a VPC

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- Tutorial: Create a VPC for use with a DB cluster (IPv4 only)
- Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB cluster. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

  For more information, see Scenarios for accessing a DB cluster in a VPC.
- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

  If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the *Amazon Elastic Compute Cloud User Guide*.

  For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

> **Note**
>
> When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn't guarantee that the DB cluster will run on a dedicated host.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon Aurora IP addressing and Migrating to IPv6 in the *Amazon VPC User Guide.*

When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

> **Note**
>
> For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

Shared subnets

You can create a DB cluster in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB cluster from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB cluster.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora supports both IPv4 and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the *Amazon VPC User Guide*.

Dual-stack mode

When a DB cluster can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB cluster over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

Topics

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (dual-stack mode).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB cluster.

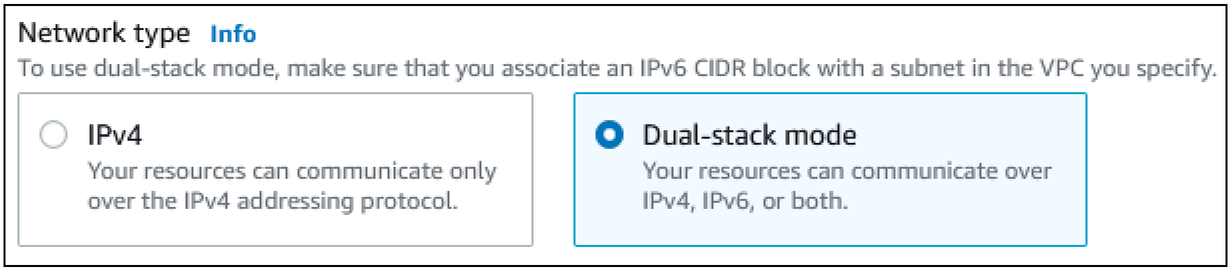
To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the describe-db-subnet-groups command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB cluster, you can specify dual-stack mode to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.



Network type Info

To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

○ IPv4
Your resources can communicate only over the IPv4 addressing protocol.

● Dual-stack mode
Your resources can communicate over IPv4, IPv6, or both.

When you use the AWS CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

To determine whether a DB cluster is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB cluster.

Modifying IPv4-only DB clusters to use dual-stack mode

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

It is recommended that you change the network type of your Amazon Aurora DB clusters during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-cluster` command.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. Modifying the DB subnet group of a DB cluster can cause downtime.

If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.

We recommend that you run the modify-db-cluster API with only the `--network-type` parameter with value `DUAL` to change the network of an Amazon Aurora cluster to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime.

If you can't connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

    a. Associate an IPv6 CIDR block with your VPC.

    For instructions, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.

  b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

     For instructions, see [Add an IPv6 CIDR block to your subnet](#) in the *Amazon VPC User Guide*.

  c. Confirm that the DB subnet group supports dual-stack mode.

     If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

     If you are using the AWS CLI, run the [describe-db-subnet-groups](#) command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.

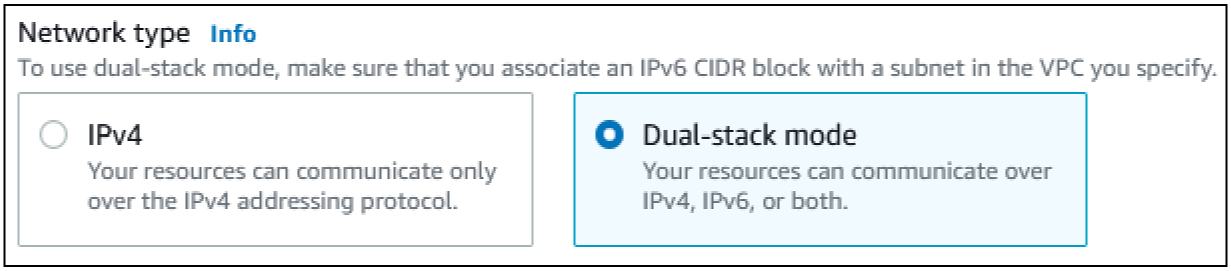
2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see [Security group rules](#) in the *Amazon VPC User Guide*.

3. Modify the DB cluster to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

   If you are using the console, make sure that the following settings are correct:

   - **Network type – Dual-stack mode**



Network type Info

To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

○ IPv4
Your resources can communicate only over the IPv4 addressing protocol.

● Dual-stack mode
Your resources can communicate over IPv4, IPv6, or both.

   - **DB subnet group –** The DB subnet group that you configured in a previous step
   - **Security group –** The security that you configured in a previous step

   If you are using the AWS CLI, make sure that the following settings are correct:

   - `--network-type` – `dual`
   - `--db-subnet-group-name` – The DB subnet group that you configured in a previous step

- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-cluster --db-cluster-identifier my-cluster --network-type "DUAL"
```

4. Confirm that the DB cluster supports dual-stack mode.

   If you are using the console, choose the **Configuration** tab for the DB cluster. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

   If you are using the AWS CLI, run the describe-db-clusters command, and make sure that the `NetworkType` value for the DB cluster is `dual`.

   Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

   ```
   dig db-instance-endpoint AAAA
   ```

   Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

Availability of dual-stack network DB clusters

The following DB engine versions support dual-stack network DB clusters, except in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Canada West (Calgary), Europe (Spain), Europe (Zurich), Israel (Tel Aviv), and Middle East (UAE) Regions:

- Aurora MySQL versions:
  - 3.02 and higher 3 versions
  - 2.09.1 and higher 2 versions

  For more information about Aurora MySQL versions, see the *Release Notes for Aurora MySQL*.
- Aurora PostgreSQL versions:
  - 14.3 and higher 14 versions
  - 13.7 and higher 13 versions

For more information about Aurora PostgreSQL versions, see the *Release Notes for Aurora PostgreSQL*.

Limitations for dual-stack network DB clusters

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB clusters that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.r3 DB instance classes.
- You can't use RDS Proxy with dual-stack mode DB clusters.

Hiding a DB cluster in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet. In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see A DB cluster in a VPC accessed by an EC2 instance in the same VPC.

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance

You can modify a DB cluster to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

> **Note**
>
> If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group
- Step 4: Create a DB instance in the VPC

Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets, or see Create a VPC in the *Amazon VPC User Guide*.

Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

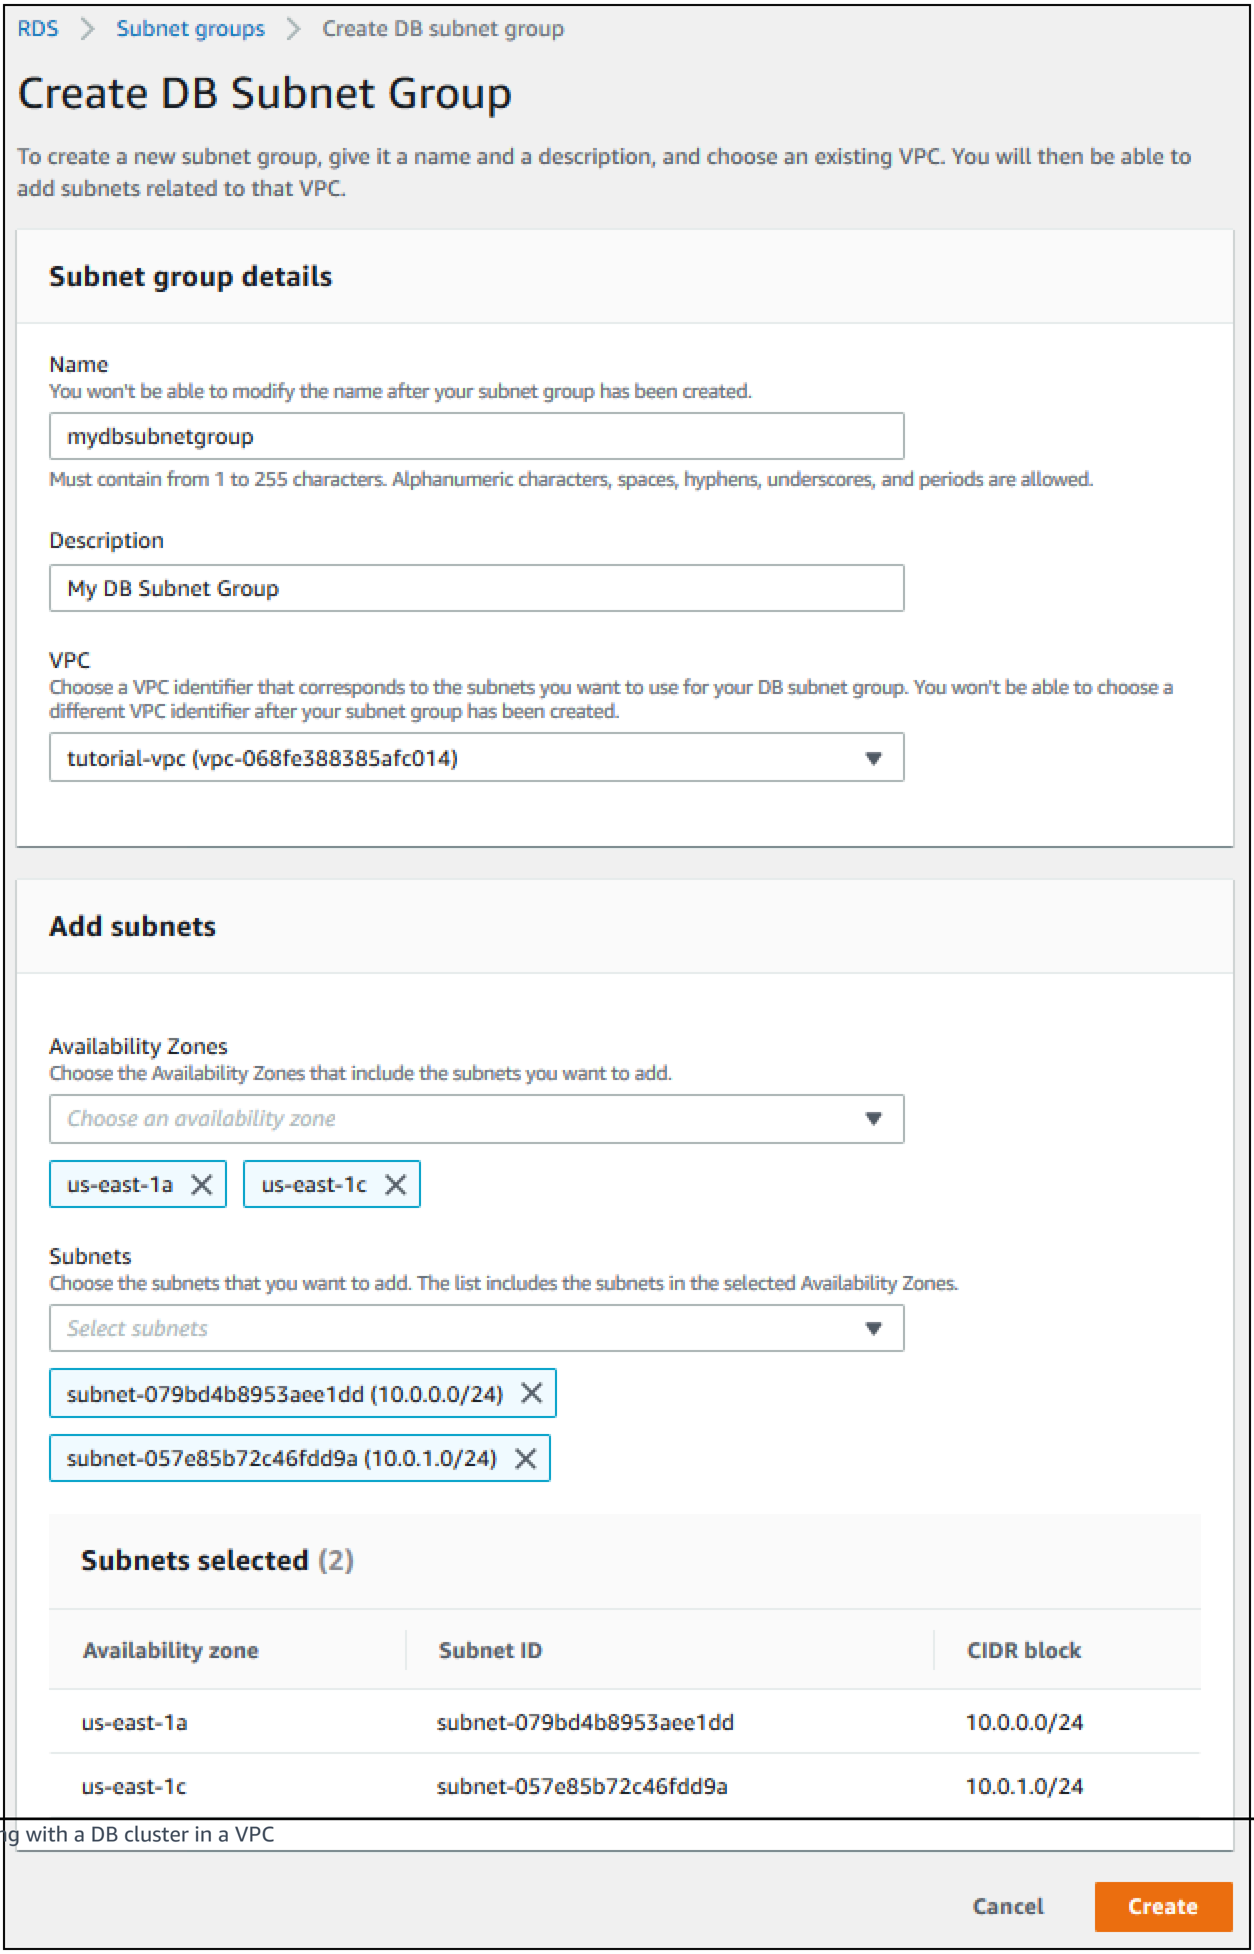
For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the *Amazon VPC User Guide*.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.



Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

Subnet group details

Name
You won't be able to modify the name after your subnet group has been created.
mydbsubnetgroup
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Description
My DB Subnet Group

VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

us-east-1c	subnet-057e85b72c46fdd9a	10.0.1.0/24

8. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see Create a VPC security group for a private DB cluster, or see Control traffic to resources using security groups in the *Amazon VPC User Guide*.

Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

> **Note**
>
> If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.

For details on how to create a DB cluster, see Creating an Amazon Aurora DB cluster.

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

> **Note**
>
> Updating VPCs isn't currently supported for Aurora DB clusters.

Scenarios for accessing a DB cluster in a VPC

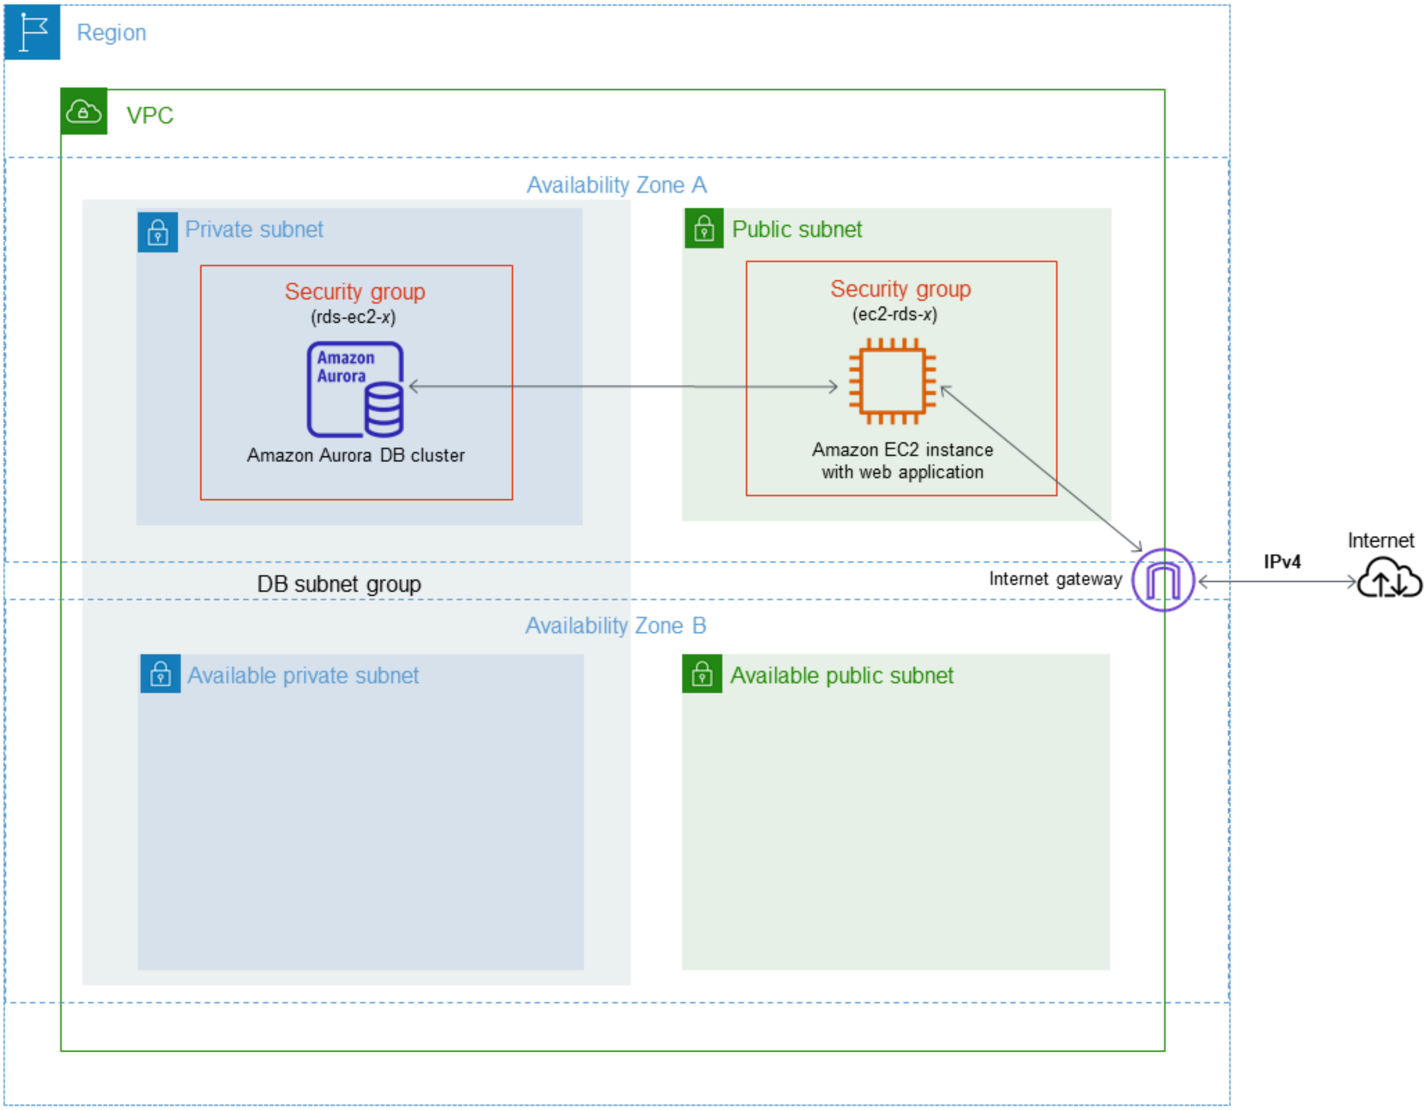
Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- An EC2 instance in the same VPC
- An EC2 instance in a different VPC
- A client application through the internet
- A private network

A DB cluster in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.



The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only).

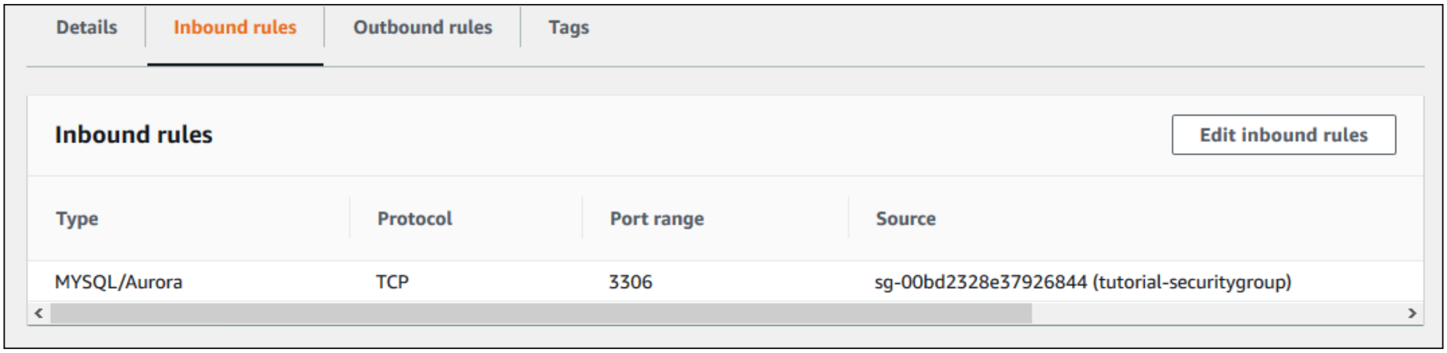
> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance .

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB cluster, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.



Inbound rules

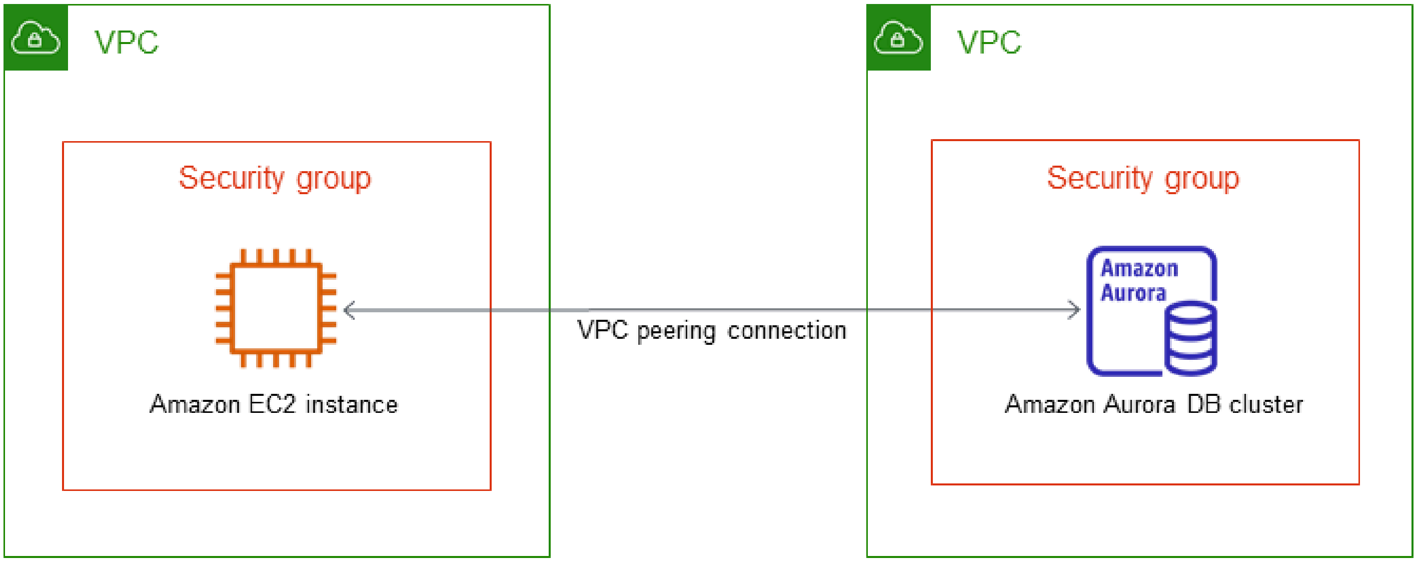
Type	Protocol	Port range	Source
MYSQL/Aurora	TCP	3306	sg-00bd2328e37926844 (tutorial-securitygroup)

For more information about connecting to the DB cluster from your EC2 instance, see Connecting to an Amazon Aurora DB cluster.

A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.

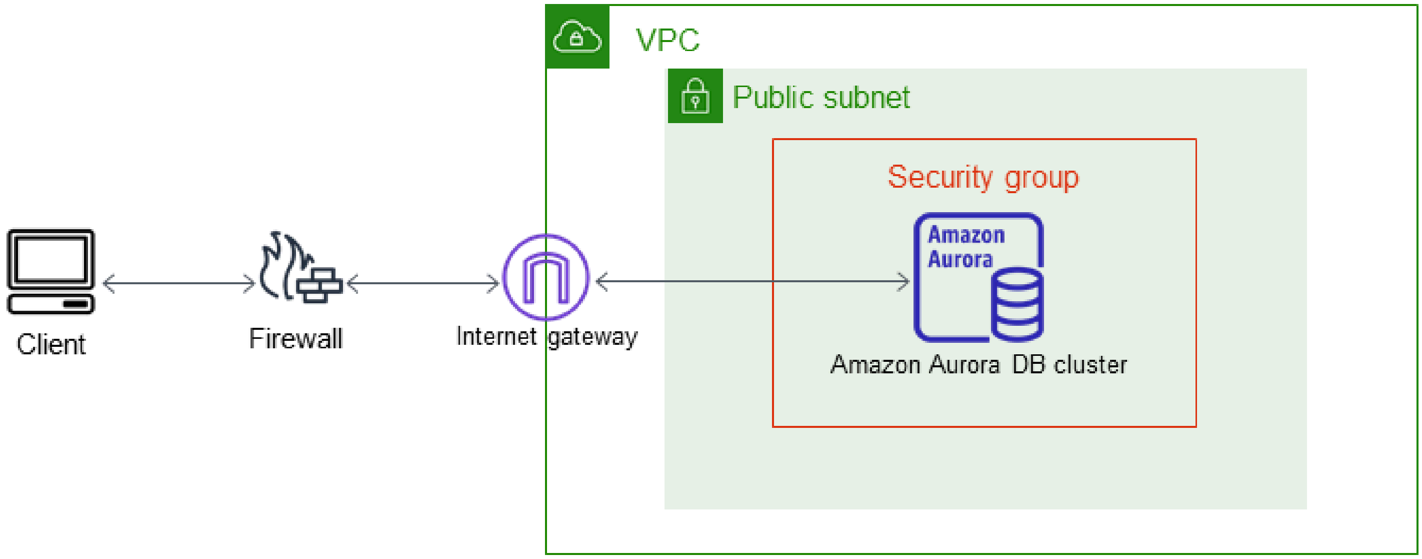


A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the *Amazon Virtual Private Cloud User Guide*.

A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.



We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.

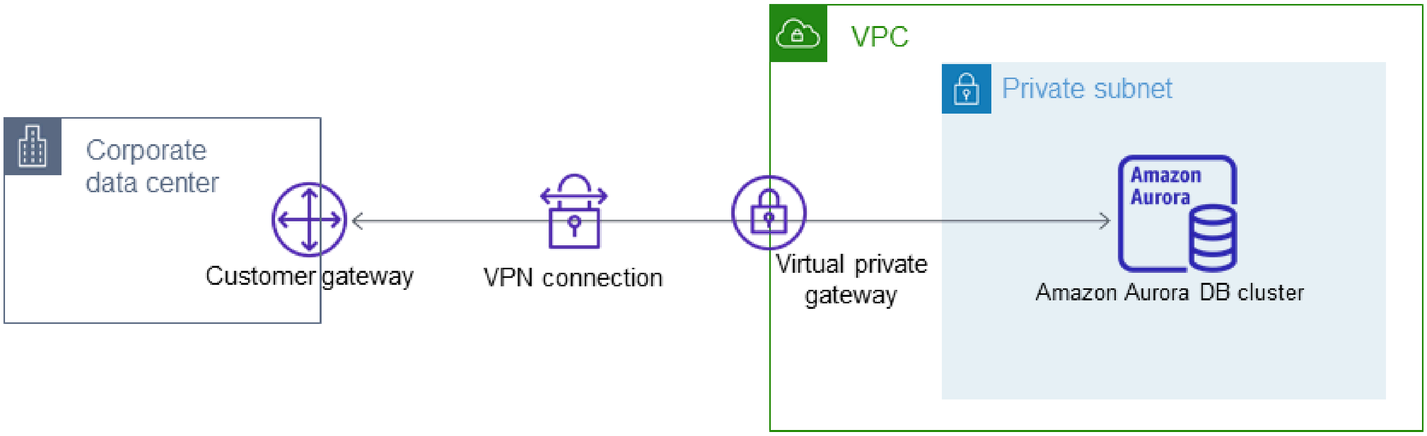
For information about creating a DB clusters in a VPC, see Creating a DB cluster in a VPC.

A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?
- An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

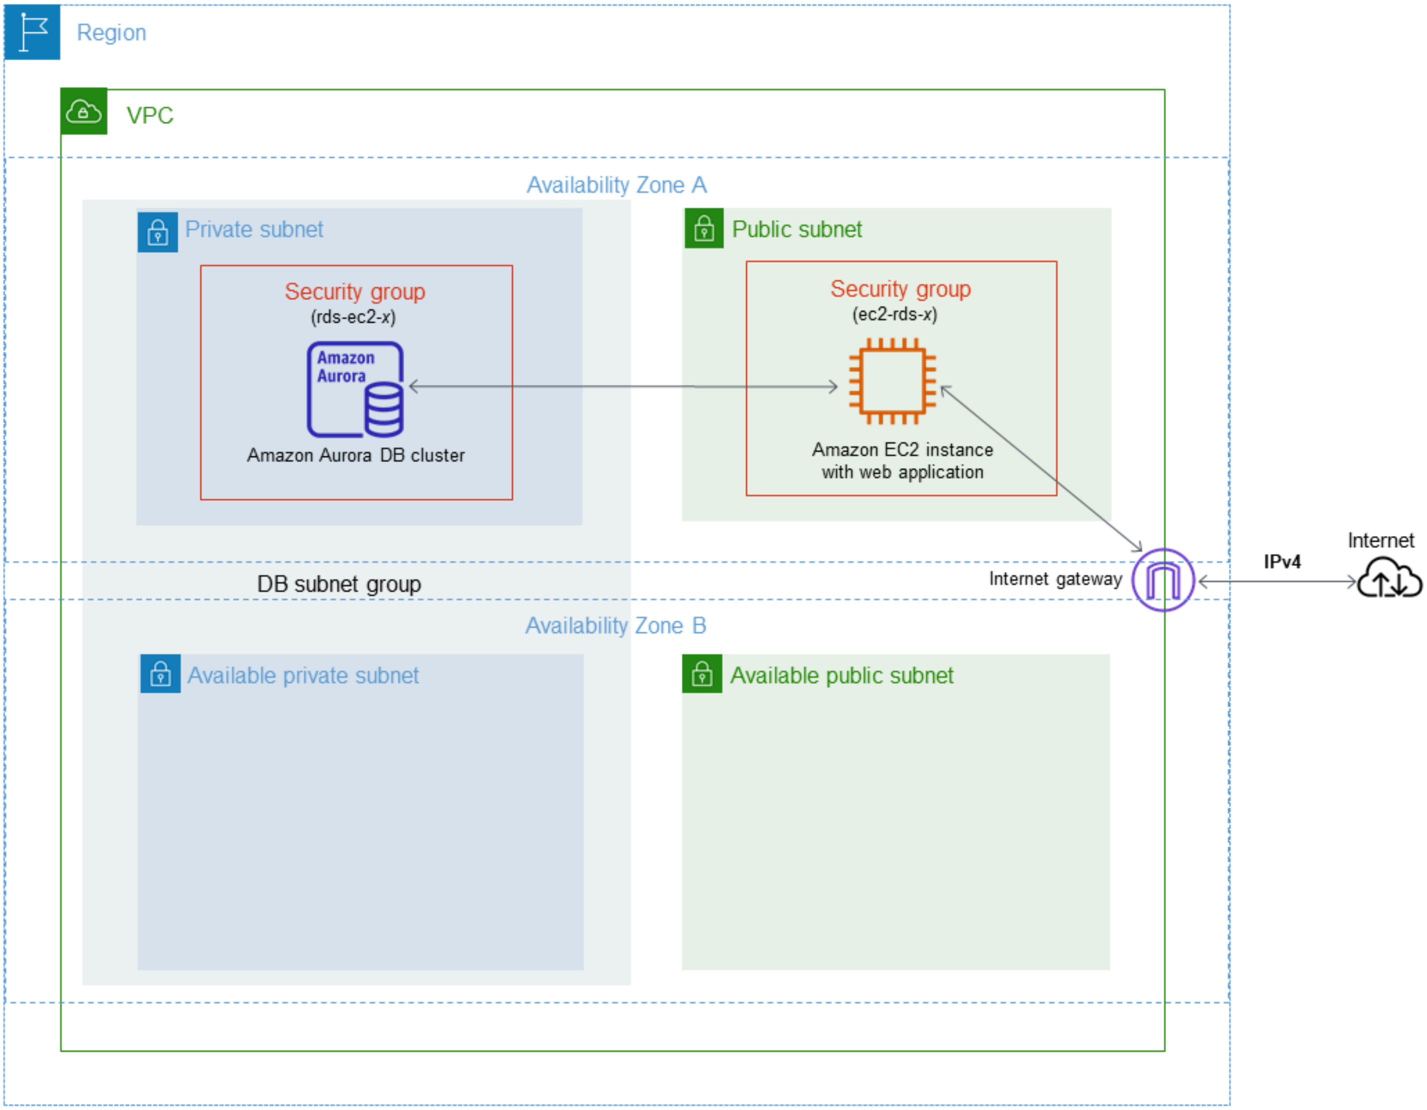


For more information, see Internetwork traffic privacy.

Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC.



Your DB cluster needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon Aurora DB cluster. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:

    - **Name tag auto-generation – `tutorial`**
    - **IPv4 CIDR block – `10.0.0.0/16`**
    - **IPv6 CIDR block – No IPv6 CIDR block**
    - **Tenancy – Default**
    - **Number of Availability Zones (AZs) – 2**
    - **Customize AZs –** Keep the default values.

- **Number of public subnet – 2**
- **Number of private subnets – 2**
- **Customize subnets CIDR blocks** – Keep the default values.
- **NAT gateways ($) – None**
- **VPC endpoints – None**
- **DNS options** – Keep the default values.

6. Choose **Create VPC**.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name:** **`tutorial-securitygroup`**
   - **Description:** **`Tutorial Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*`identifier`* (tutorial-vpc)**
4. Add inbound rules to the security group.

   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is `203.0.113.25/32`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> ⚠ **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

- **Type: SSH**
- **Source:** The IP address or range from Step a, for example: **`203.0.113.25/32`**.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

- **Type: HTTP**
- **Source: `0.0.0.0/0`**

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clustersin your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.

3. On the **Create security group** page, set these values:

   - **Security group name: `tutorial-db-securitygroup`**
   - **Description: `Tutorial DB Instance Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*`identifier`* (tutorial-vpc)**

4. Add inbound rules to the security group.

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster. By doing so, you can store and retrieve data from your web application to your database.

      - **Type: `MySQL/Aurora`**
      - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.

5. Choose **Create security group** to create the security group.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

      You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

   - **Name: `tutorial-db-subnet-group`**
   - **Description: `Tutorial DB Subnet Group`**
   - **VPC: tutorial-vpc (vpc-*`identifier`*)**
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

> **Note**
>
> If you created this VPC to complete Tutorial: Create a web server and an Amazon Aurora DB cluster, create the DB cluster by following the instructions in Create an Amazon Aurora DB cluster.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

> **Note**
>
> If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group.

   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   b. In the navigation pane, choose **Subnet groups**.

   c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.

   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. In the list, identify the VPC that you created, such as **tutorial-vpc**.

   d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Security Groups**.

   c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.

   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.

   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the VPC.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. Select the VPC you want to delete, such as **tutorial-vpc**.

   d. For **Actions**, choose **Delete VPC**.

   The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

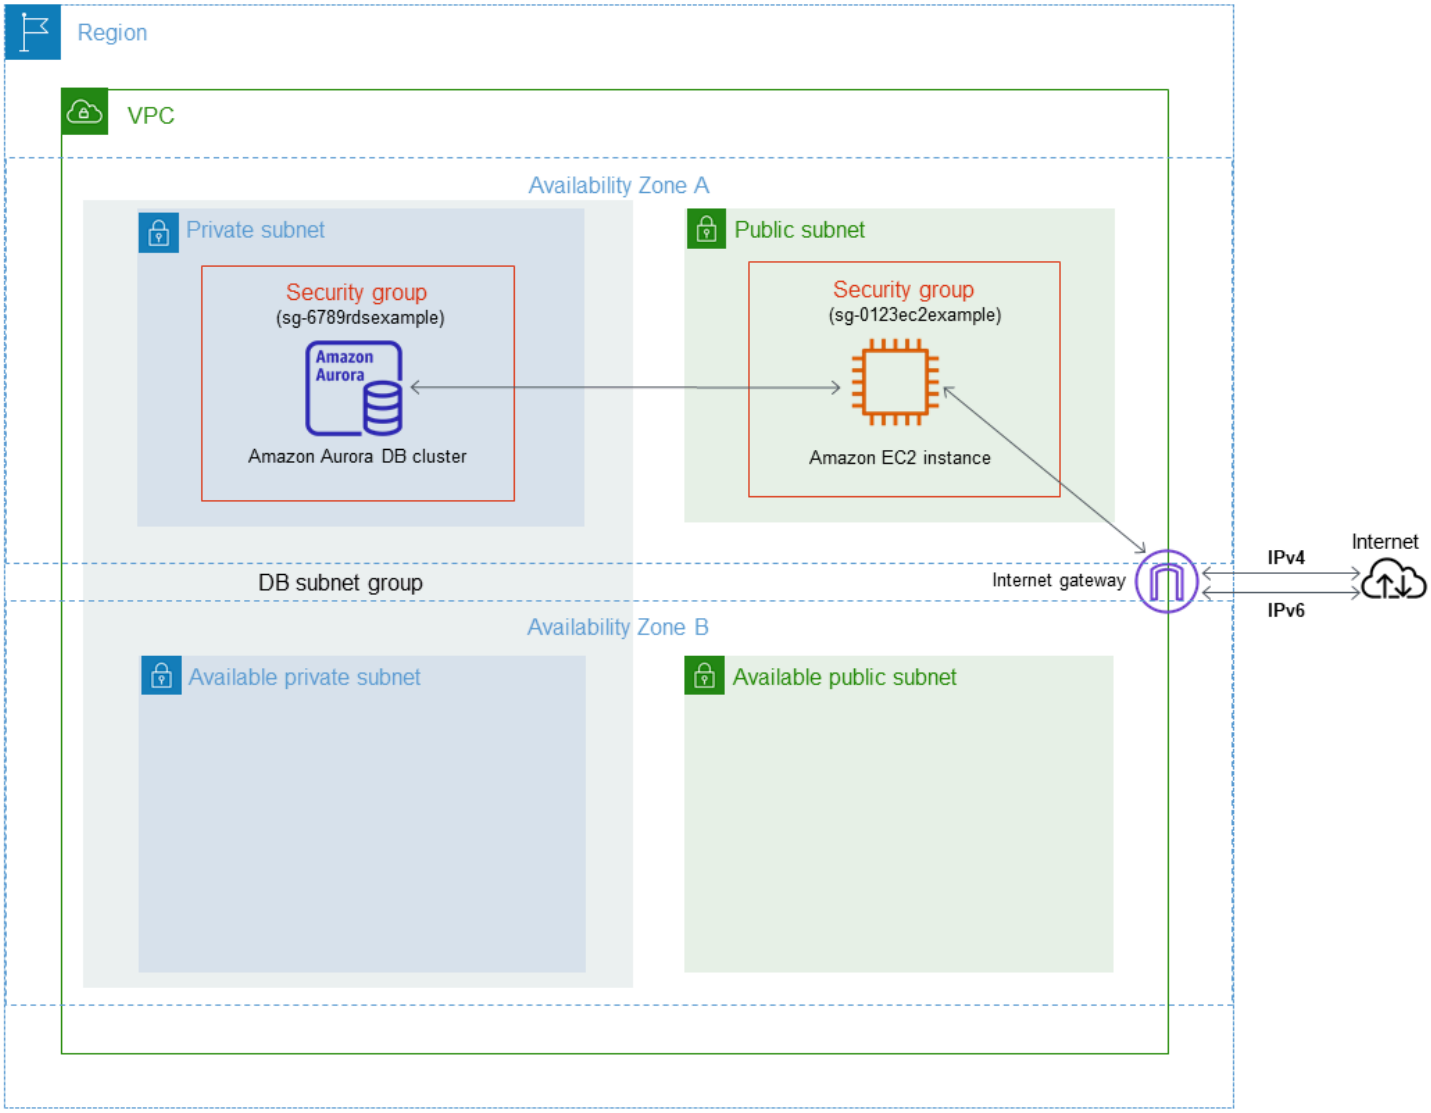
Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon Aurora IP addressing.

Dual-stack network clusters are supported in most regions. For more information see Availability of dual-stack network DB clusters. To see the limitations of dual-stack mode, see Limitations for dual-stack network DB clusters.

The following diagram shows this scenario.



For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC.

Your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:

   - **Name tag auto-generation – `tutorial-dual-stack`**
   - **IPv4 CIDR block – `10.0.0.0/16`**
   - **IPv6 CIDR block – Amazon-provided IPv6 CIDR block**
   - **Tenancy – Default**
   - **Number of Availability Zones (AZs) – 2**
   - **Customize AZs –** Keep the default values.
   - **Number of public subnet – 2**
   - **Number of private subnets – 2**
   - **Customize subnets CIDR blocks –** Keep the default values.
   - **NAT gateways ($) – None**
   - **Egress only internet gateway – No**
   - **VPC endpoints – None**
   - **DNS options –** Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-dual-stack-securitygroup`**
   - **Description: `Tutorial Dual-Stack Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*`identifier`* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group.

   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

      An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`. An example of an Internet Protocol version 6 (IPv6) address range is `2001:db8:1234:1a00::/64`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> ⚠ **Warning**
>
> If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

   b. In the **Inbound rules** section, choose **Add rule**.

   c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

   - **Type: SSH**
   - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **`203.0.113.25/32`**. An example of an IPv6 IP address is **`2001:DB8::/32`**.

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

   - **Security group name: `tutorial-dual-stack-db-securitygroup`**
   - **Description: `Tutorial Dual-Stack DB Instance Security Group`**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*`identifier`* (tutorial-dual-stack-vpc)**

4. Add inbound rules to the security group:

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB cluster. Doing this means that you can send data from your EC2 instance to your database.

      - **Type: MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.

5. To create the security group, choose **Create security group**.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is `DUAL` compatible, all subnets must be `DUAL` compatible. To be `DUAL` compatible, a subnet must have an IPv6 CIDR associated with it.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

   - **Name: `tutorial-dual-stack-db-subnet-group`**
   - **Description: `Tutorial Dual-Stack DB Subnet Group`**
   - **VPC: tutorial-dual-stack-vpc (vpc-*`identifier`*)**

6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*`identifier`*) created in Create a VPC with private and public subnets.
- **Subnet** – Choose an existing public subnet, such as **subnet-*`identifier`* | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in Create a VPC security group for a public Amazon EC2 instance.
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in Create a VPC security group for a public Amazon EC2 instance. Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.

     
     Network type Info

     To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

     ○ IPv4
     Your resources can communicate only over the IPv4 addressing protocol.

     ● Dual-stack mode
     Your resources can communicate over IPv4, IPv6, or both.

   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in [Create a VPC with private and public subnets](#).

     The VPC must have subnets in different Availability Zones.
   - **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in [Create a DB subnet group](#).
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in [Create a VPC security group for a private DB cluster](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for Aurora DB clusters.

Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in Connect to your Linux instance in the *Amazon EC2 User Guide*.

To connect to your Aurora MySQL DB cluster from the Amazon EC2 instance, follow the instructions in Connect to an Aurora MySQL DB cluster.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB clusters. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group:

   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.

   d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Security Groups**.

   c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.

   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.

   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.

   c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

   d. For **Actions**, choose **Delete NAT gateway**.

   e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

5. Delete the VPC:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.

   d. For **Actions**, choose **Delete VPC**.

   The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

   e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

6. Release the Elastic IP addresses:

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

   b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.

   c. Select the Elastic IP address that you want to release.

   d. For **Actions**, choose **Release Elastic IP addresses**.

   e. On the confirmation page, choose **Release**.

Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

Topics

- Quotas in Amazon Aurora
- Naming constraints in Amazon Aurora
- Amazon Aurora size limits

Quotas in Amazon Aurora

Each AWS account has quotas, for each AWS Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

Name	Default	Adjus e	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	No	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed

Name	Default	Adjustable	Description
			in this account in the current Region
DB instances	Each supported Region: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB subnet groups	Each supported Region: 50	Yes	The maximum number of DB subnet groups
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current AWS Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.

Name	Default	Adjustable	Description
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current AWS Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots

Name	Default	Adjuse	Description
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups
Parameter groups	Each supported Region: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current AWS Region
Read replicas per primary	Each supported Region: 15	Yes	The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.
Reserved DB instances	Each supported Region: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current AWS Region
Rules per security group	Each supported Region: 20	No	The maximum number of rules per DB security group
Security groups	Each supported Region: 25	Yes	The maximum number of DB security groups
Security groups (VPC)	Each supported Region: 5	No	The maximum number of DB security groups per Amazon VPC

Name	Default	Adjustable	Description
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group
Tags per resource	Each supported Region: 50	No	The maximum number of tags per Amazon RDS resource
Total storage for all DB instances	Each supported Region: 100,000 Gigabytes	Yes	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.
If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.
Backups managed by AWS Backup are considered manual DB clustersnapshots, but don't count toward the manual cluster snapshot quota. For information about AWS Backup, see the *AWS Backup Developer Guide*.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the Service Quotas console.
- From the AWS CLI, use the request-service-quota-increase AWS CLI command.

For more information, see the *Service Quotas User Guide*.

Naming constraints in Amazon Aurora

The following table describes naming constraints in Amazon Aurora.

Resource or item	Constraints
DB cluster identifier	Identifiers have these naming constraints: • Must contain 1–63 alphanumeric characters or hyphens. • First character must be a letter. • Can't end with a hyphen or contain two consecutive hyphens. • Must be unique for all DB instances per AWS account, per AWS Region.
Initial database name	Database name constraints differ between Aurora MySQL and PostgreSQL. For more information, see the available settings when creating each DB cluster.
Master user name	Master user name constraints differ for each database engine. For more information, see the available settings when creating each DB cluster.

Resource or item	Constraints
Master password	The password for the database master user can include any printable ASCII character except `/`, `'`, `"`, `@`, or a space. For Oracle, & is an additional character limitation. The password has the following number of printable ASCII characters depending on the DB engine: • Aurora MySQL: 8–41 • Aurora PostgreSQL: 8–99
DB parameter group name	These names have these constraints: • Must contain 1–255 alphanumeric characters. • First character must be a letter. • Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
DB subnet group name	These names have these constraints: • Must contain 1–255 characters. • Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Amazon Aurora size limits

Storage size limits

An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB) for the following engine versions:

- All available Aurora MySQL version 3 versions; Aurora MySQL version 2, versions 2.09 and higher
- All available Aurora PostgreSQL versions

For lower engine versions, the maximum size of an Aurora cluster volume is 64 TiB. For more information, see How Aurora storage automatically resizes.

To monitor the remaining storage space, you can use the `AuroraVolumeBytesLeftTotal` metric. For more information, see Cluster-level metrics for Amazon Aurora.

SQL table size limits

For an Aurora MySQL DB cluster, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

Table space ID limits

The maximum table space ID for Aurora MySQL is 2147483647. If you frequently create and drop tables, make sure to be aware of your table space IDs and plan to use logical dumps. For more information, see Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump.

Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Aurora.

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  > **Note**
  >
  > When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see Provide access to the DB cluster in the VPC by creating a security group.

> **Note**
>
> Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see Hiding a DB cluster in a VPC from the internet.
- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

  To configure an internet gateway for a subnet

  1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
  2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
  3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
  4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
  5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet

gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

   If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

      For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.
   c. Choose **Save routes**.

   Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see Working with a DB cluster in a VPC.

Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299

  Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/
vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

  Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
 open
  connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

> **Note**
>
> Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

Amazon RDS security issues

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your AWS account. For information about creating users in AWS IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges.

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance in a DB cluster, see Modifying a DB instance in a DB cluster.

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.

- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group.

Freeable memory issues in Amazon Aurora

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Overview of monitoring metrics in Amazon Aurora.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see Aurora DB instance classes.

You can also change the memory settings. For example, on Aurora MySQL , you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

For Aurora Serverless v2, `FreeableMemory` represents the amount of unused memory that's available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. You might have the instance scaled down to relatively low capacity, but it still reports a high value for `FreeableMemory`, because the instance can scale up. That memory isn't available right now, but you can get it if you need it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity, `FreeableMemory` increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of `0`, the DB instance has scaled up as much as it can. It's nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance. For more information, see Important Amazon CloudWatch metrics for Aurora Serverless v2.

For Aurora Serverless v1, you can change the capacity range to use more ACUs. For more information, see Modifying an Aurora Serverless v1 DB cluster.

Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

Topics

Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started.

During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `AuroraBinlogReplicaLag` metric.

The `AuroraBinlogReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MySQL `SHOW REPLICA STATUS` command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the `AuroraBinlogReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `AuroraBinlogReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL read replication failure. A `AuroraBinlogReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

Note

Previous versions of Aurora MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using Aurora MySQL version 1 or 2, then use `SHOW SLAVE STATUS`. Use `SHOW REPLICA STATUS` for Aurora MySQL version 3 and higher.

The `AuroraBinlogReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `AuroraBinlogReplicaLag` metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `AuroraBinlogReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type parameter` to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
- Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

  For Linux, macOS, or Unix:

  ```
  PROMPT> mysqldump \
      -h <endpoint> \
      --port=<port> \
      -u=<username> \
      -p <password> \
      database_name table1 table2 > /dev/null
  ```

  For Windows:

  ```
  PROMPT> mysqldump ^
      -h <endpoint> ^
      --port=<port> ^
      -u=<username> ^
      -p <password> ^
      database_name table1 table2 > /dev/null
  ```

Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `Error` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0057. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, check the error in the MySQL error message documentation.

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.
- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to *0* to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```
  alter table <schema>.<table_name> engine=innodb;
  ```
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error. Your Aurora MySQL DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see mysql_rds_skip_repl_error.
- If you encounter a binary log (binlog) position issue, you can change the replica replay position. You do so with the `mysql.rds_next_master_log` command for Aurora MySQL version 1 and 2. You do so with the `mysql.rds_next_source_log` command for Aurora MySQL version 3 and higher. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see mysql_rds_next_master_log.
- If you encounter a temporary performance issue due to high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. This way, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see Troubleshooting a MySQL read replica problem.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql_rds_set_configuration procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics

- Using the Query API
- Troubleshooting applications on Aurora

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the *Amazon EC2 API Reference.*

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.`*n* notation. Values of *n* are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- Retrieving errors
- Troubleshooting tips

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon Aurora.

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
    my $xp = XML::XPath->new(xml =>$response);
    if ( $xp->find("//Error") )
    {print "There was an error processing your request:\n", " Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", " ",
    $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking http://status.aws.amazon.com.
- Check the structure of your request.

  Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check AWS re:Post.

  Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to AWS re:Post.

Document history

Current API version: 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the *Amazon Relational Database Service User Guide*.

> **Note**
>
> Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see Document history in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the What's New with Database? page. For **Products**, choose **Amazon Aurora**. Then search using keywords such as **`global database`** or **`Serverless`**.

Change	Description	Date
AWS Python Driver generally available	The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more information, see Connecting to Aurora DB clusters with the AWS drivers.	May 23, 2024
Zero-ETL integrations available in China Regions	Zero-ETL integrations are now available in the AWS Regions China (Beijing) and China (Ningxia). For more informati	May 21, 2024

	on, see Zero-ETL integrations with Amazon Redshift.	
RDS Proxy is available in more Regions	RDS Proxy is now available in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary), and Europe (Zurich) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	May 21, 2024
Amazon RDS Extended Support	Creating or restoring an Aurora MySQL version 2 or 3, or Aurora PostgreSQL version 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the Aurora end of standard support date for your database engine. For more information, see Using Amazon RDS Extended Support.	March 21, 2024

Data filtering for zero-ETL integrations	Amazon RDS supports data filtering at the database and table level for zero-ETL integrations with Amazon Redshift. For more information, see Data filtering for Aurora zero-ETL integrations with Amazon Redshift.	March 20, 2024
Aurora MySQL integrations with Amazon Bedrock	You can now integrate Amazon Aurora MySQL databases with Amazon Bedrock to power generative AI applications. For more information, see Using Amazon Aurora machine learning with Aurora MySQL.	March 8, 2024
New AWS managed policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon RDS updates to AWS managed policies.	February 27, 2024

Amazon RDS support for AWS Secrets Manager in the Israel (Tel Aviv) Region	Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	February 21, 2024
Amazon RDS Extended Support	Amazon RDS now automatically enables Amazon RDS Extended Support when Aurora MySQL and Aurora PostgreSQL major engine versions in your DB clusters and global clusters reach the Aurora end of standard support date. For more information, see Using Amazon RDS Extended Support.	February 15, 2024
Aurora PostgreSQL 16.1 supports Babelfish for Aurora PostgreSQL 4.0.0	Aurora PostgreSQL 16.1 supports Babelfish 4.0.0. For a list of new features, see 16.1. For a list of features supported in each Babelfish release, see Supported functionality in Babelfish by version. For usage information, see Working with Babelfish for Aurora PostgreSQL.	January 31, 2024

Update to default CA Certificate	The default CA certificate is set to `rds-ca-rsa2048-g1`. For more information, see Using SSL/TLS to encrypt a connection to a DB cluster.	January 26, 2024
RDS Proxy is available in the Europe (Spain) Region	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 8, 2024
RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned	You can now use RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned DB clusters. With RDS Data API, you can access your Aurora clusters through a secure HTTP endpoint and run SQL statements without using database drivers or managing connections. For more information, see Using RDS Data API.	December 21, 2023
Aurora PostgreSQL integrations with Amazon Bedrock	You can now integrate Amazon Aurora PostgreSQL databases with Amazon Bedrock to power generative AI applications. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL.	December 21, 2023

Amazon Aurora is available in the Canada West (Calgary) Region	Amazon Aurora is now available in the Canada West (Calgary) Region. For more information, see Regions and Availability Zones.	December 20, 2023
Amazon RDS supports viewing and responding to recommendations	Amazon Aurora recommendations now includes threshold based proactive and machine learning based reactive recommendations. For more information, see Viewing and responding to Amazon Aurora recommendations.	December 19, 2023
Aurora PostgreSQL zero-ETL integrations with Amazon Redshift (preview)	You can now create zero-ETL integrations with Amazon Redshift using an Aurora PostgreSQL source DB cluster. For the preview release, you must create all integrations in the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-east-2) AWS Region. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	November 28, 2023
Amazon Aurora PostgreSQL supports global database write forwarding	You can now enable write forwarding on secondary clusters in an Aurora PostgreSQL-based global database. For more information, see Using write forwarding in an Aurora PostgreSQL global database.	November 9, 2023

Aurora PostgreSQL support for Optimized Reads	You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. For more information, see Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads.	November 8, 2023
Amazon RDS exports Performance Insights metrics to Amazon CloudWatch	Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see Exporting Performance Insights metrics to CloudWatch.	November 8, 2023
Aurora MySQL zero-ETL integrations with Amazon Redshift general availability	Zero-ETL integrations with Amazon Redshift are now generally available for Aurora MySQL. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	November 7, 2023

Aurora PostgreSQL support for RDS Blue/Green Deployments	You can now create a blue/green deployment from an Aurora PostgreSQL DB cluster. For more information, see Using Amazon RDS Blue/Gree n Deployments for database updates.	October 26, 2023
Aurora MySQL supports server-side encryption with AWS KMS keys (SSE-KMS)	In Aurora MySQL version 3.05 and higher, you can use SSE-KMS, including AWS managed keys and customer managed keys, for server-side encryption of data that you load from or save to Amazon S3. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket and Saving data from an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket.	October 25, 2023
Aurora MySQL optimizations reduce database restart time	In Aurora MySQL version 3.05 and higher, we've introduce d optimizations that reduce the database restart time. These optimizations provide up to 65% less downtime than without optimizations, and fewer disruptions to your database workloads, after a restart. For more information, see Optimizations to reduce database restart time.	October 25, 2023

Update to AWS managed policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see Amazon RDS updates to AWS managed policies.	October 23, 2023
Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch	The **DB_PERF_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see Creating CloudWatch alarms to monitor Amazon Aurora.	September 20, 2023
Amazon Aurora supports point-in-time recovery (PITR) with AWS Backup	You can now manage Aurora automated (continuous) backups in AWS Backup and restore to specified times from them. For more information, see Restoring a DB cluster to a specified time using AWS Backup.	September 7, 2023

Amazon RDS Extended Support	Amazon Aurora announces the upcoming ability to continue running Aurora MySQL and Aurora PostgreSQL major engine versions in your DB instances past the Aurora end of standard support date. For more information, see Using Amazon RDS Extended Support.	September 1, 2023
Amazon Aurora MySQL extends support for Percona XtraBackup	You can now perform physical migrations of MySQL 8.0 databases to Aurora MySQL version 3 DB clusters. For more information, see Physical migration from MySQL by using Percona XtraBackup and Amazon S3.	August 24, 2023

Aurora global database supports global database failover	Aurora global database now supports managed global failover, allowing you to more easily recover from a true Regional disaster or complete service-level outage. To learn more about this feature, see Performing managed failovers for Aurora global databases. The feature previously called "managed planned failover" is now called "switchover." For information about switchovers, see Performing switchovers for Amazon Aurora global databases.	August 21, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 17, 2023

Update to AWS managed policy permissions	The addition of new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and addition of new managed policy `AmazonRDSPerformanceInsightsFullAccess` allows you generate a DB load analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 16, 2023
Amazon RDS supports DB load time period analysis with Performance Insights	Performance Insights allows you to create performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see Analyzing DB load for a period of time.	August 16, 2023
Amazon Aurora supports retaining automated backups for DB clusters	You can now retain automated backups for deleted Aurora clusters and restore them to a specified point in time. For more information, see Retaining automated backups.	August 4, 2023

Amazon Aurora is available in the Israel (Tel Aviv) Region	Amazon Aurora is now available in the Israel (Tel Aviv) Region. For more information, see Regions and Availability Zones.	August 1, 2023
Amazon Aurora MySQL supports local (in-cluster) write forwarding	You can now forward write operations from a reader DB instance to a writer DB instance within an Aurora MySQL DB cluster. For more information, see Using write forwarding in an Amazon Aurora MySQL DB cluster.	July 31, 2023
Amazon Aurora supports Aurora Serverless v2 in an additional AWS Region	You can now create Aurora Serverless v2 DB clusters in the Asia Pacific (Melbourne) AWS Region. For information about Aurora Serverless v2, see Using Aurora Serverless v2.	June 28, 2023
Amazon Aurora introduces zero-ETL integrations with Amazon Redshift (preview)	Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an Aurora MySQL DB cluster. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	June 28, 2023

Amazon RDS provides combined Performance Insights and CloudWatch metrics view in the Performance Insights dashboard	Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. For more information, see Viewing combined metrics in the Amazon RDS console.	May 24, 2023
Amazon Aurora supports the db.r7g instance classes	You can now use the db.r7g instance classes to create Aurora DB clusters. For more information, see Aurora DB instance classes.	May 11, 2023
Amazon Aurora supports a new DB cluster storage configuration	With Aurora I/O-Optimized, you pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations. For more information, see Storage configurations for Amazon Aurora DB clusters.	May 11, 2023
Amazon Aurora supports Aurora Serverless v2 in additional AWS Regions	You can now create Aurora Serverless v2 DB clusters in the following AWS Regions: Asia Pacific (Hyderabad), Europe (Spain) Europe (Zurich), and Middle East (UAE). For information about Aurora Serverless v2, see Using Aurora Serverless v2.	May 4, 2023

Aurora Serverless v1 supports conversion to provisioned	You can convert an Aurora Serverless v1 DB cluster directly to a provisioned DB cluster. For more information, see Converting an Aurora Serverless v1 DB cluster to provisioned.	April 27, 2023
Aurora Serverless v1 supports Amazon Aurora PostgreSQL version 13	You can now create Aurora Serverless v1 DB clusters that run Aurora PostgreSQL version 13. For more information, see Aurora Serverless v1.	April 27, 2023
Amazon Aurora support for AWS Secrets Manager in the China Regions	Amazon Aurora supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see Password management with Amazon Aurora and AWS Secrets Manager.	April 20, 2023
Amazon Aurora supports publishing events with tags to topic subscribers	Amazon Aurora event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see Amazon RDS event notification tags and attributes.	April 17, 2023

Update to IAM service-linked role permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see Amazon RDS updates to AWS managed policies.	March 30, 2023
Amazon Aurora supports global databases in the Asia Pacific (Melbourne) Region	You can now create Aurora global databases in the Asia Pacific (Melbourne) Region. For information about Aurora global databases, see Using Amazon Aurora global databases.	March 22, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to Amazon CloudWatch. For more information, see Amazon RDS updates to AWS managed policies.	March 16, 2023
RDS Proxy is available in the China Regions	RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 15, 2023

Amazon Aurora supports Aurora Serverless v2 in the China Regions	Aurora Serverless v2 is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Aurora Serverless v2.	March 15, 2023
RDS Proxy is available in the Asia Pacific (Jakarta) Region	RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 8, 2023
Amazon Aurora MySQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB clusters. For more information, see Using Kerberos authentication for Aurora MySQL.	March 8, 2023
Amazon Aurora supports global databases in additional AWS Regions	You can now create Aurora global databases in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about Aurora global databases, see Using Amazon Aurora global databases.	March 6, 2023

Amazon Aurora supports copying DB cluster snapshots in additional AWS Regions	You can now copy DB cluster snapshots in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Asia Pacific (Melbourne), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about copying DB cluster snapshots , see Copying a DB cluster snapshot.	March 6, 2023
Amazon DevOps Guru for RDS supports proactive insights	Amazon DevOps Guru for RDS publishes proactive insights with recommendations to help you address issues in your Aurora databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works.	February 28, 2023
Amazon Aurora MySQL version 1 is deprecated	Aurora MySQL version 1 (compatible with MySQL 5.6) has been deprecated. For more information, see How long Amazon Aurora major versions remain available.	February 28, 2023

Aurora Serverless v1 supports setting the DB cluster maintenance window	You can now set the maintenance window for Aurora Serverless v1 DB clusters. For more information, see Adjusting the preferred DB cluster maintenance window.	February 27, 2023
Amazon Aurora supports Database Activity Streams in the Asia Pacific (Hyderabad), Europe (Spain), and Middle East (UAE) Regions.	For more information, see Database Activity Streams.	January 27, 2023
Amazon Aurora is available in the Asia Pacific (Melbourne) Region	Amazon Aurora is now available in the Asia Pacific (Melbourne) Region. For more information, see Regions and Availability Zones.	January 23, 2023
Specify certificate authority (CA) during DB cluster creation	You can now specify which CA to use for a DB cluster's server certificate during DB cluster creation. For more information, see Certificate authorities.	January 5, 2023

Aurora MySQL 3.* support for backtracking	Aurora MySQL 3.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see Backtracking an Aurora DB cluster.	January 4, 2023
Use Amazon RDS Blue/Green Deployments available in additional AWS Regions	The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	December 22, 2022
Update to IAM service-linked role permissions	The AmazonRDSServiceRolePolicy policy now grants additional permissions to AWS Secrets Manager. For more information, see Amazon RDS updates to AWS managed policies.	December 22, 2022

Amazon Aurora integrates with AWS Secrets Manager for password management	Aurora can manage the master user password for a DB cluster in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager.	December 22, 2022
Amazon Aurora supports Aurora Serverless v2 in additional AWS Regions	Aurora Serverless v2 is now available in the Africa (Cape Town) and Europe (Milan) Regions. For more information, see Aurora Serverless v2.	December 21, 2022
Aurora PostgreSQL supports RDS Proxy with PostgreSQL 14	You can now create an RDS Proxy with an Aurora PostgreSQL 14 DB cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	December 13, 2022
Amazon Aurora alerts you to recent anomalies detected by Amazon DevOps Guru	The database details page of the console alerts you both to current and anomalies that occurred in the past 24 hours. For more information, see How DevOps Guru for RDS works.	December 13, 2022
Amazon RDS Proxy supports global databases	You can now use RDS Proxy with Aurora global databases . For more information, see Using RDS Proxy with Aurora global databases.	December 7, 2022

Aurora PostgreSQL DB clusters support Trusted Language Extensions for PostgreSQL	Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. For more information, see Working with Trusted Language Extensions for PostgreSQL.	November 30, 2022
Amazon GuardDuty RDS Protection monitors for access threats	When you turn on GuardDuty RDS Protection, GuardDuty consumes RDS login events from your Aurora databases, monitors these events, and profiles them for potential insider threats or external actors. When GuardDuty RDS Protection detects a potential threat, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see Monitoring threats with GuardDuty RDS Protection.	November 30, 2022

Use Amazon RDS Blue/Green Deployments for database updates	You can make changes to a DB cluster in a staging environment and test the changes without affecting your production DB cluster. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	November 27, 2022
Amazon Aurora is available in the Asia Pacific (Hyderabad) Region	Amazon Aurora is now available in the Asia Pacific (Hyderabad) Region. For more information, see Regions and Availability Zones.	November 22, 2022
Amazon Aurora is available in the Europe (Spain) Region	Amazon Aurora is now available in the Europe (Spain) Region. For more information, see Regions and Availability Zones.	November 16, 2022
Amazon Aurora is available in the Europe (Zurich) Region	Amazon Aurora is now available in the Europe (Zurich) Region. For more information, see Regions and Availability Zones.	November 9, 2022

Amazon Aurora supports exporting data to Amazon S3 from DB clusters	You can now export Aurora cluster data directly to S3, without having to create a snapshot first. For more information, see Exporting DB cluster data to Amazon S3.	October 27, 2022
Amazon Aurora MySQL supports faster exports to Amazon S3	You can now see up to 10x faster performance for exporting DB cluster snapshot data to S3 for MySQL 5.7- and 8.0-compatible Aurora MySQL clusters. For more information, see Exporting DB cluster snapshot data to Amazon S3.	October 20, 2022
Amazon Aurora supports automatically setting up connectivity between an Aurora DB cluster and an EC2 instance	You can use the AWS Management Console to set up connectivity between an existing Aurora DB cluster and an EC2 instance. For more information, see Connecting an EC2 instance and an Aurora DB cluster automatically.	October 14, 2022
AWS JDBC Driver for PostgreSQL generally available	The AWS JDBC Driver for PostgreSQL is a client driver designed for Aurora PostgreSQL. The AWS JDBC Driver for PostgreSQL is now generally available. For more information, see Connecting with the AWS JDBC Driver for PostgreSQL.	October 6, 2022

Amazon Aurora supports in-place upgrade for MySQL 5.7-compatible Aurora MySQL	You can perform an in-place upgrade to change an existing MySQL 5.7-compatible Aurora MySQL cluster into a MySQL 8.0-compatible Aurora MySQL cluster. For more information, see Upgrading from Aurora MySQL 2.x to 3.x.	September 26, 2022
Performance Insights shows the top 25 SQL queries	In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see Overview of the Top SQL tab.	September 13, 2022
Aurora MySQL supports a new DB instance class	You can now use the db.r6i DB instance class for Aurora MySQL DB clusters. For more information, see DB instance classes.	September 13, 2022
Amazon Aurora is available in the Middle East (UAE) Region	Amazon Aurora is now available in the Middle East (UAE) Region. For more information, see Regions and Availability Zones.	August 30, 2022

Amazon Aurora supports automatically setting up connectivity with an EC2 instance	When you create an Aurora DB cluster, you can use the AWS Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance.	August 22, 2022
Amazon Aurora supports dual-stack mode	DB clusters can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB cluster over IPv4, IPv6, or both. For more information, see Amazon Aurora IP addressing.	August 17, 2022
Amazon Aurora supports in-place upgrade for PostgreSQL-compatible Aurora Serverless v1	You can perform an in-place upgrade for a PostgreSQL 10-compatible Aurora Serverless v1 cluster to change an existing cluster into a PostgreSQL 11-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see Modifying an Aurora Serverless v1 DB cluster.	August 8, 2022

Performance Insights supports the Asia Pacific (Jakarta) Region	Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more informati on, see AWS Region support for Performance Insights.	July 21, 2022
Amazon Aurora supports a new DB instance class	You can now use the db.r6i DB instance class for Aurora PostgreSQL DB clusters. For more information, see DB instance classes.	July 14, 2022
RDS Performance Insights supports additional retention periods	Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance data for longer than 7 days, you can specify from 1–24 months. For more informati on, see Pricing and data retention for Performance Insights.	July 1, 2022
Amazon Aurora supports in-place upgrade for MySQL-compatible Aurora Serverless v1	You can perform an in-place upgrade for a MySQL 5.6-compatible Aurora Serverles s v1 cluster to change an existing cluster into a MySQL 5.7-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure , see Modifying an Aurora Serverless v1 DB cluster.	June 16, 2022

Aurora supports turning on Amazon DevOps Guru in the RDS console	You can turn on DevOps Guru coverage for your Aurora databases from within the RDS console. For more information, see Setting up DevOps Guru for RDS.	June 9, 2022
Amazon Aurora supports publishing events to encrypted Amazon SNS topics	Amazon Aurora can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see Subscribing to Amazon RDS event notification.	June 1, 2022
Amazon RDS publishes usage metrics to Amazon CloudWatch	The `AWS/Usage` namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon Aurora.	April 28, 2022

Data API result sets in JSON format	An optional parameter for the `ExecuteStatement` function causes the query result set to be returned as a string in JSON format. The JSON result set is simple and convenient to transform into a data structure in your application's language. For more information, see Processing query results in JSON format.	April 27, 2022
Amazon Aurora Serverless v2 is now generally available	Amazon Aurora Serverless v2 is generally available for all users. For more information, see Using Aurora Serverless v2.	April 21, 2022
Aurora MySQL supports configurable cipher suites	With Aurora MySQL, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For more information, see Configuring cipher suites for connections to Aurora MySQL DB clusters.	April 15, 2022
Aurora PostgreSQL supports RDS Proxy with PostgreSQL 13	You can now create an RDS Proxy with an Aurora PostgreSQL 13 DB cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	April 4, 2022

Release Notes for Aurora PostgreSQL	There is now a separate guide for the Amazon Aurora PostgreSQL release notes. For more information, see *Release Notes for Aurora PostgreSQL*.	March 22, 2022
Release Notes for Aurora MySQL	There is now a separate guide for the Amazon Aurora MySQL release notes. For more information, see *Release Notes for Aurora MySQL*.	March 22, 2022
Aurora PostgreSQL supports multi-major version upgrades	You can now perform version upgrades of Aurora PostgreSQL DB clusters across multiple major versions. For more information, see How to perform a major version upgrade.	March 4, 2022
Aurora PostgreSQL supports configurable cipher suites	With Aurora PostgreSQL versions 11.8 and higher, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For information about using configurable cipher suites with Aurora PostgreSQL, see Configuring cipher suites for connections to Aurora PostgreSQL DB clusters.	March 4, 2022

AWS JDBC Driver for MySQL generally available	The AWS JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The AWS JDBC Driver for MySQL is now generally available. For more information, see Connecting with the Amazon Web Services JDBC Driver for MySQL.	March 2, 2022
Aurora PostgreSQL 13.5 supports Babelfish for Aurora PostgreSQL 1.1.0	Aurora PostgreSQL 13.5 supports Babelfish 1.1.0. For a list of new features, see 13.5. For a list of features supported in each Babelfish release, see Supported functionality in Babelfish by version. For usage information, see Working with Babelfish for Aurora PostgreSQL.	February 28, 2022
Amazon Aurora supports Database Activity Streams in the Asia Pacific (Jakarta) Region	For more information, see Support for AWS Regions for database activity streams.	February 16, 2022

Performance Insights supports new API operations	Performance Insights now supports the following API operations: `GetResourceMetadata` , `ListAvailableResourceDimensions` , and `ListAvailableResourceMetrics` . For more information, see Retrieving metrics with the Performance Insights API in this manual and the *Amazon RDS Performance Insights API Reference*.	January 12, 2022
Amazon RDS Proxy supports events	RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see Working with RDS Proxy events.	January 11, 2022
RDS Proxy available in additional AWS Regions	RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 5, 2022

Amazon Aurora is available in the Asia Pacific (Jakarta) Region	Amazon Aurora is now available in the Asia Pacific (Jakarta) Region. For more information, see Regions and Availability Zones.	December 13, 2021
DevOps Guru for Amazon RDS provides detailed insights and recommendations for Amazon Aurora	DevOps Guru for RDS mines Performance Insights for performance-related data. Using this data, the service analyzes the performance of your Amazon Aurora DB instances and can help you resolve performance issues. To learn more, see Analyzing performance anomalies with DevOps Guru for RDS in this guide and see Overview of DevOps Guru for RDS in the *Amazon DevOps Guru User Guide*.	December 1, 2021
Aurora PostgreSQL supports RDS Proxy with PostgreSQL 12	You can now create an RDS Proxy with an Aurora PostgreSQL 12 database cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	November 22, 2021
Aurora supports AWS Graviton2 instance classes for Database Activity Streams	You can use database activity streams with the db.r6g instance class for Aurora MySQL and Aurora PostgreSQ L. For more information, see Supported DB instance classes.	November 3, 2021

Amazon Aurora support for cross-account AWS KMS keys	You can use a KMS key from a different AWS account for encryption when exporting DB snapshots to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	November 3, 2021
Amazon Aurora supports Babelfish for Aurora PostgreSQL	Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see Working with Babelfish for Aurora PostgreSQL.	October 28, 2021
Aurora Serverless v1 can require SSL for connections	The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL are supported now for Aurora Serverless v1. For more information, see Using TLS/SSL with Aurora Serverless v1.	October 26, 2021
Amazon Aurora supports Performance Insights in additional AWS Regions	Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see AWS Region support for Performance Insights.	October 5, 2021

Configurable autoscaling timeout for Aurora Serverless v1	You can choose how long Aurora Serverless v1 waits to find an autoscaling point. If no autoscaling point is found during that period, Aurora Serverless v1 cancels the scaling event or forces the capacity change, depending on the timeout action that you selected. For more information, see Autoscaling for Aurora Serverless v1.	September 10, 2021
Aurora supports X2g and T4g instance classes	Both Aurora MySQL and Aurora PostgreSQL can now use X2g and T4g instance classes. The instance classes that you can use depend on the version of Aurora MySQL or Aurora PostgreSQ L. For information about supported instance types, see DB instance classes.	September 10, 2021
Amazon RDS supports RDS Proxy in a shared VPC	You can now create an RDS Proxy in a shared virtual private cloud (VPC). For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora User Guide.	August 6, 2021

Aurora version policy page	The *Amazon Aurora User Guide* now includes a section with general information about Aurora versions and associated policies. For details, see Amazon Aurora versions.	July 14, 2021
Exclude Data API events from an AWS CloudTrail trail	You can exclude Data API events from a CloudTrail trail. For more information, see Excluding Data API events from an AWS CloudTrail trail.	July 2, 2021
Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions	Newly supported extensions include pg_bigm, pg_cron, pg_partman, and pg_proctab. For more information, see Extension versions for Amazon Aurora PostgreSQL-Compatible Edition.	June 17, 2021
Cloning for Aurora Serverless clusters	You can now create cloned clusters that are Aurora Serverless. For information about cloning, see Cloning a volume for an Aurora DB cluster.	June 16, 2021
Aurora global databases available in China (Beijing) and China (Ningxia) Regions	You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see Working with Amazon Aurora global databases.	May 19, 2021

FIPS 140-2 support for Data API	The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see Data API availability.	May 14, 2021
AWS JDBC Driver for PostgreSQL (preview)	The AWS JDBC Driver for PostgreSQL, now available in preview, is a client driver designed for the high availability of Aurora PostgreSQL. For more information, see Connecting with the Amazon Web Services JDBC Driver for PostgreSQL (preview).	April 27, 2021
The Data API available in additional AWS Regions	The Data API is now available in the Asia Pacific (Seoul) and Canada (Central) Regions. For more information, see Availability of the Data API.	April 9, 2021
Amazon Aurora supports the Graviton2 DB instance classes	You can now use the Graviton2 DB instance classes db.r6g.x to create DB clusters running MySQL or PostgreSQL. For more information, see DB instance class types.	March 12, 2021

RDS Proxy endpoint enhancements	You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	March 8, 2021
Amazon Aurora is available in the Asia Pacific (Osaka) Region	Amazon Aurora is now available in the Asia Pacific (Osaka) Region. For more information, see Regions and Availability Zones.	March 1, 2021
Aurora PostgreSQL supports enabling both IAM and Kerberos authentication on the same DB cluster	Aurora PostgreSQL now supports enabling both IAM authentication and Kerberos authentication on the same DB cluster. For more information, see Database authentication with Amazon Aurora.	February 24, 2021

Aurora global database now supports managed planned failover	Aurora global database now supports managed planned failover, allowing you to more easily change the primary AWS Region of your Aurora global database. You can use managed planned failover with healthy Aurora global databases only. To learn more, see Disaster recovery and Amazon Aurora global databases. For reference information, see `FailoverGlobalCluster` in the *Amazon RDS API Reference*.	February 11, 2021
Data API for Aurora Serverless now supports more data types	With the Data API for Aurora Serverless, you can now use `UUID` and `JSON` data types as input to your database. Also with the Data API for Aurora Serverless, you can now have a `LONG` type value returned from your database as a `STRING` value. To learn more, see Calling the Data API. For reference information about supported data types, see `SqlParameter` in the *Amazon RDS Data Service API Reference*.	February 2, 2021

Aurora PostgreSQL supports major version upgrades to PostgreSQL 12	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 12. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	January 28, 2021
Aurora MySQL supports in-place upgrade	You can upgrade your Aurora MySQL 1.x cluster to Aurora MySQL 2.x, preserving the DB instances, endpoints, and so on of the original cluster. This in-place upgrade technique avoids the inconvenience of setting up a whole new cluster by restoring a snapshot. It also avoids the overhead of copying all your table data into a new cluster. For more information, see Upgrading the major version of an Aurora MySQL DB cluster from 1.x to 2.x.	January 11, 2021
AWS JDBC Driver for MySQL (preview)	The AWS JDBC Driver for MySQL, now available in preview, is a client driver designed for the high availability of Aurora MySQL. For more information, see Connecting with the Amazon Web Services JDBC Driver for MySQL (preview).	January 7, 2021

Aurora supports database activity streams on secondary clusters of a global database	You can start a database a database activity stream on a primary or secondary cluster of Aurora PostgreSQL or Aurora MySQL. For supported engine versions, see Limitations of Aurora global databases.	December 22, 2020
Multi-master clusters with 4 DB instances	The maximum number of DB instances in an Aurora MySQL multi-master cluster is now four. Formerly, the maximum was two DB instances. For more information, see Working with Aurora Multi-Master Clusters.	December 17, 2020
Aurora PostgreSQL supports AWS Lambda functions	You can now invoke AWS Lambda function for your Aurora PostgreSQL DB clusters. For more information, see Invoking a Lambda function from an Aurora PostgreSQL DB cluster.	December 11, 2020
Amazon Aurora supports the Graviton2 DB instance classes in preview	You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see DB instance class types.	December 11, 2020

Amazon Aurora Serverless v2 is now available in preview.	Amazon Aurora Serverless v2 is available in preview. To work with Amazon Aurora Serverless v2, apply for access. For more information, see the Aurora Serverless v2 page.	December 1, 2020

Aurora PostgreSQL is now available for Aurora Serverless in more AWS Regions.	Aurora PostgreSQL is now available for Aurora Serverless in more AWS Regions. You can now choose to run Aurora PostgreSQL Serverless v1 in the same AWS Regions that offer Aurora MySQL Serverless v1. Additional AWS Regions with Aurora Serverless support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless, see Supported Regions and Aurora DB engines for Aurora Serverless v1. Amazon RDS Data API for Aurora Serverless is also now available in these same AWS Regions. For a list of all Regions with support for the Data API for Aurora Serverless, see Data API with Aurora MySQL Serverless v1	November 24, 2020

Amazon RDS Performance Insights introduces new dimensions	You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.	November 24, 2020
Aurora Serverless supports Aurora PostgreSQL version 10.12	Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the AWS Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see Supported Regions and Aurora DB engines for Aurora Serverless v1.	November 4, 2020
The Data API now supports tag-based authorization	The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see Authorizing access to the Data API.	October 27, 2020

Amazon Aurora extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see Exporting DB snapshot data to Amazon S3.	October 22, 2020
Aurora global database supports cloning	You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the AWS Management Console and choosing the **Create clone** menu option. You can also use the AWS CLI and run the `restore-db-cluster-to-point-in-time` command with the `--restore-type copy-on-write` option. Using the AWS Management Console or the AWS CLI, you can also clone DB clusters from your Aurora global databases across AWS accounts. For more information about cloning, see Cloning an Aurora DB cluster volume.	October 19, 2020

Amazon Aurora supports dynamic resizing for the cluster volume	Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as `DROP TABLE`. To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see Managing Performance and Scaling for Aurora DB Clusters.	October 13, 2020
Amazon Aurora supports volume sizes up to 128 TiB	New and existing Aurora cluster volumes can now grow to a maximum size of 128 tebibytes (TiB). For more information, see How Aurora storage grows.	September 22, 2020
Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China (Ningxia) Region	You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see DB instance classes.	September 3, 2020

Aurora parallel query enhancements	Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature. Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the `DYNAMIC` row format. Parallel query clusters can use AWS Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the `READ COMMITTED` isolation	September 2, 2020

	level. You can also now create parallel query clusters in additional AWS Regions. For more information about the parallel query feature and these enhancements, see Working with parallel query for Aurora MySQL.	
Changes to Aurora MySQL parameter binlog_rows_query_log_events	You can now change the value of the Aurora MySQL configuration parameter `binlog_rows_query_log_events` . Formerly, this parameter wasn't modifiable.	August 26, 2020

Support for automatic minor version upgrades for Aurora MySQL	With Aurora MySQL, the setting **Enable auto minor version upgrade** now takes effect when you specify it for an Aurora MySQL DB cluster. When you enable auto minor version upgrade, Aurora automatically upgrades to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database. For Aurora MySQL, this feature applies only to Aurora MySQL version 2, which is compatible with MySQL 5.7. Initially, the automatic upgrade procedure brings Aurora MySQL DB clusters to version 2.07.2. For more information about how this feature works with Aurora MySQL, see Database Upgrades and Patches for Amazon Aurora MySQL.	August 3, 2020
Aurora PostgreSQL supports major version upgrades to PostgreSQL version 11	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 11. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	July 28, 2020

Amazon Aurora supports AWS PrivateLink	Amazon Aurora now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Aurora in the AWS network. For more information, see Amazon Aurora and interface VPC endpoints (AWS PrivateLink).	July 9, 2020
RDS Proxy generally available	RDS Proxy is now generally available. You can use RDS Proxy with RDS for MySQL, Aurora MySQL, RDS for PostgreSQL, and Aurora PostgreSQL for production workloads. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	June 30, 2020

Aurora global database write forwarding	You can now enable write capability on secondary clusters in a global database. With write forwarding, you issue DML statements on a secondary cluster, Aurora forwards the write to the primary cluster, and the updated data is replicated to all the secondary clusters. For more information, see Write forwarding for secondary AWS Regions with an Aurora global database.	June 18, 2020
Aurora supports integration with AWS Backup	You can use AWS Backup to manage backups of Aurora DB clusters. For more information, see Overview of backing up and restoring an Aurora DB cluster.	June 10, 2020
Aurora PostgreSQL supports db.t3.large DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.t3.large DB instance classes. For more information, see DB instance classes.	June 5, 2020

Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective (RPO)	You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see Cross-Region Disaster Recovery for Aurora global databases.	June 4, 2020
Aurora MySQL supports database monitoring with database activity streams	Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see Using database activity streams.	June 2, 2020
The query editor available in additional AWS Regions	The query editor for Aurora Serverless is now available in additional AWS Regions. For more information, see Availability of the query editor.	May 28, 2020
The Data API available in additional AWS Regions	The Data API is now available in additional AWS Regions. For more information, see Availability of the Data API.	May 28, 2020

RDS Proxy available in Canada (Central) Region	You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see Managing connections with Amazon RDS proxy (preview).	May 28, 2020
Aurora global database and cross-Region read replicas	For an Aurora global database, you can now create an Aurora MySQL cross-Region read replica from the primary cluster in the same region as a secondary cluster. For more information about Aurora Global Database and cross-Region read replicas, see Working with Amazon Aurora global database and Replicating Amazon Aurora MySQL DB.	May 18, 2020
RDS Proxy available in more AWS Regions	You can now use the RDS Proxy preview in the US West (N. California) Region, the Europe (London) Region, the Europe (Frankfurt) Region, the Asia Pacific (Seoul) Region, the Asia Pacific (Mumbai) Region, the Asia Pacific (Singapore) Region, and the Asia Pacific (Sydney) Region. For more information about RDS Proxy, see Managing connections with Amazon RDS proxy (preview).	May 13, 2020

Aurora PostgreSQL-Compatible Edition supports on-premises or self-hosted Microsoft active directory	You can now use an on-premises or self-hosted Active Directory for Kerberos authentication of users when they connect to your Aurora PostgreSQL DB clusters. For more information, see Using Kerberos authentication with Aurora PostgreSQL.	May 7, 2020
Aurora MySQL multi-master clusters available in more AWS Regions	You can now create Aurora multi-master clusters in the Asia Pacific (Seoul) Region, the Asia Pacific (Tokyo) Region, the Asia Pacific (Mumbai) Region, and the Europe (Frankfurt) Region. For more information about multi-master clusters, see Working with Aurora multi-master clusters.	May 7, 2020
Performance Insights supports analyzing statistics of running Aurora MySQL queries	You can now analyze statistics of running queries with Performance Insights for Aurora MySQL DB instances. For more information, see Analyzing statistics of running queries.	May 5, 2020

Java client library for Data API generally available	The Java client library for the Data API is now generally available. You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see Using the Java client library for Data API.	April 30, 2020
Amazon Aurora is available in the Europe (Milan) Region	Amazon Aurora is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 28, 2020
Amazon Aurora is available in the Europe (Milan) Region	Amazon Aurora is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 27, 2020
Amazon Aurora is available in the Africa (Cape Town) Region	Amazon Aurora is now available in the Africa (Cape Town) Region. For more information, see Regions and Availability Zones.	April 22, 2020

Aurora PostgreSQL now supports db.r5.16xlarge and db.r5.8xlarge DB instance classes	You can now create Aurora PostgreSQL DB clusters running PostgreSQL that use the db.r5.16xlarge and db.r5.8xlarge DB instance classes. For more information, see Hardware specifications for DB instance classes for Aurora.	April 8, 2020
Amazon RDS proxy for PostgreSQL	Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your cluster and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see Managing connections with Amazon RDS proxy (preview).	April 8, 2020
Aurora global databases now support Aurora PostgreSQL	You can now create Aurora global databases for the PostgreSQL database engine. An Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see Working with Amazon Aurora global database.	March 10, 2020

Support for major version upgrades for Aurora PostgreSQL	With Aurora PostgreSQL, you can now upgrade the DB engine to a major version. By doing so, you can skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	March 4, 2020
Aurora PostgreSQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Aurora PostgreSQL DB clusters. For more information, see Using Kerberos authentication with Aurora PostgreSQL.	February 28, 2020
The Data API supports AWS PrivateLink	The Data API now supports creating Amazon VPC endpoints for Data API calls to keep traffic between applications and the Data API in the AWS network. For more information, see Creating an Amazon VPC endpoint (AWS PrivateLink) for the Data API.	February 6, 2020

Aurora machine learning support in Aurora PostgreSQL	The aws_ml Aurora PostgreSQL extension provides functions you use in your database queries to call Amazon Comprehend for sentiment analysis and SageMaker to run your own machine learning models. For more information, see Using machine learning (ML) capabilities with Aurora.	February 5, 2020
Aurora PostgreSQL supports exporting data to Amazon S3	You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 b ucket. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.	February 5, 2020
Support for exporting DB snapshot data to Amazon S3	Amazon Aurora supports exporting DB snapshot data to Amazon S3 for MySQL and PostgreSQL. For more information, see Exporting DB snapshot data to Amazon S3.	January 9, 2020

Aurora MySQL release notes in document history	This section now includes history entries for Aurora MySQL-Compatible Edition release notes for versions released after August 31, 2018. For the full release notes for a specific version, choose the link in the first column of the history entry.	December 13, 2019
Amazon RDS proxy	You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the Aurora MySQL database engine. For more information, see Managing connections with Amazon RDS proxy (preview).	December 3, 2019

Data API for Aurora Serverless v1 supports data type mapping hints	You can now use a hint to instruct the Data API for Aurora Serverless v1 to send a `String` value to the database as a different type. For more information, see Calling the data API.	November 26, 2019
Data API for Aurora Serverless v1 supports a Java client library (preview)	You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see Using the Java client library for Data API.	November 26, 2019
Aurora PostgreSQL is FedRAMP HIGH eligible	Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see AWS services in scope by compliance program.	November 26, 2019

READ COMMITTED isolation level enabled for Amazon Aurora MySQL replicas	You can now enable the `READ COMMITTED` isolation level on Aurora MySQL Replicas. Doing so requires enabling the `aurora_read_replica_read_committed_isolation_enabled` configuration setting at the session level. Using the `READ COMMITTED` isolation level for long-running queries on OLTP clusters can help address issues with history list length. Before enabling this setting, be sure to understand how the isolation behavior on Aurora Replicas differs from the usual MySQL implementation of `READ COMMITTED`. For more information, see Aurora MySQL isolation levels.	November 25, 2019
Performance Insights supports analyzing statistics of running Aurora PostgreSQL queries	You can now analyze statistics of running queries with Performance Insights for Aurora PostgreSQL DB instances. For more information, see Analyzing statistics of running queries.	November 25, 2019

More clusters in an Aurora global database	You can now add multiple secondary regions to an Aurora global database. You can take advantage of low latency global reads and disaster recovery across a wider geographic area. For more information about Aurora global databases, see Working with Amazon Aurora global databases.	November 25, 2019
Aurora machine learning support in Aurora MySQL	In Aurora MySQL 2.07 and higher, you can call Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of machine learning algorithms. You use the results directly in your database application by embedding calls to stored functions in your queries. For more information, see Using machine learning (ML) capabilities with Aurora.	November 25, 2019

Aurora global database no longer requires engine mode setting	You no longer need to specify `--engine-mode=global` when creating a cluster that is intended to be part of an Aurora global database. All Aurora clusters that meet the compatibility requirements are eligible to be part of a global database. For example, the cluster currently must use Aurora MySQL version 1 with MySQL 5.6 compatibility. For information about Aurora global databases, see Working with Amazon Aurora global databases.	November 25, 2019
Aurora global database is available for Aurora MySQL version 2	Starting in Aurora MySQL 2.07, you can create an Aurora global database with MySQL 5.7 compatibility. You don't need to specify the `global` engine mode for the primary or secondary clusters. You can add any new provisioned cluster with Aurora MySQL 2.07 or higher to an Aurora Global Database. For information about Aurora Global Database, see Working with Amazon Aurora global database.	November 25, 2019

Aurora MySQL hot row contention optimization available without lab mode	The hot row contention optimization is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page. The improvement involves changing the lock release algorithm used by Aurora MySQL.	November 19, 2019
Aurora MySQL hash joins available without lab mode	The hash join feature is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information about using this feature, see Working with hash joins in Aurora MySQL.	November 19, 2019
Aurora MySQL 2.* support for more db.r5 instance classes	Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see Choosing the DB instance class.	November 19, 2019

Aurora MySQL 2.* support for backtracking	Aurora MySQL 2.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see Backtracking an Aurora DB cluster.	November 19, 2019
Billing tag support for Aurora	You can now use tags to keep track of cost allocation for resources such as Aurora clusters, DB instances within Aurora clusters, I/O, backups, snapshots, and so on. You can see costs associated with each tag using AWS Cost Explorer. For more information about using tags with Aurora, see Tagging Amazon RDS resources. For general information about tags and ways to use them for cost analysis, see Using cost allocation tags and User-defined cost allocation tags.	October 23, 2019

Data API for Aurora PostgreSQL	Aurora PostgreSQL now supports using the Data API with Amazon Aurora Serverless v1 DB clusters. For more information, see Using the Data API for Aurora Serverless v1.	September 23, 2019
Aurora PostgreSQL supports uploading database logs to CloudWatch logs	You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.	August 9, 2019
Multi-master clusters for Aurora MySQL	You can set up Aurora MySQL multi-master clusters. In these clusters, each DB instance has read/write capability. For more information, see Working with Aurora multi-master clusters.	August 8, 2019

Aurora PostgreSQL supports Aurora Serverless v1	You can now use Amazon Aurora Serverless v1 with Aurora PostgreSQL. An Aurora Serverless DB cluster automatically starts up, shuts down, and scales up or down its compute capacity based on your application's needs. For more information, see Using Amazon Aurora Serverless v1.	July 9, 2019
Cross-account cloning for Aurora MySQL	You can now clone the cluster volume for an Aurora MySQL DB cluster between AWS accounts. You authorize the sharing through AWS Resource Access Manager (AWS RAM). The cloned cluster volume uses a copy-on-write mechanism, which only requires additional storage for new or changed data. For more information about cloning for Aurora, see Cloning databases in an Aurora DB cluster.	July 2, 2019
Aurora PostgreSQL supports db.t3 DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.t3 DB instance classes. For more information, see DB instance class.	June 20, 2019

Support for importing data from Amazon S3 for Aurora PostgreSQL	You can now import data from an Amazon S3 file into a table in an Aurora PostgreSQL DB cluster. For more information, see Importing Amazon S3 data into an Aurora PostgreSQL DB cluster.	June 19, 2019
Aurora PostgreSQL now provides fast failover recovery with cluster cache management	Aurora PostgreSQL now provides cluster cache management to ensure fast recovery of the primary DB instance in the event of a failover. For more information, see Fast recovery after failover with cluster cache management.	June 11, 2019
Data API for Aurora Serverless v1 generally available	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see Using the Data API for Aurora Serverless v1.	May 30, 2019
Aurora PostgreSQL supports database monitoring with database activity streams	Aurora PostgreSQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see Using database activity streams.	May 30, 2019

Amazon Aurora recommendations	Amazon Aurora now provides automated recommendations for Aurora resources. For more information, see Using Amazon Aurora recommendations.	May 22, 2019
Performance Insights support for Aurora global database	You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see Using Amazon RDS performance insights. For information about Aurora global databases, see Working with Aurora global database.	May 13, 2019
Performance Insights is available for Aurora MySQL 5.7	Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see Using Amazon RDS performance insights.	May 3, 2019
Aurora global databases available in more AWS Regions	You can now create Aurora global databases in most AWS Regions where Aurora is available. For information about Aurora global databases, see Working with Amazon Aurora global databases.	April 30, 2019

Minimum capacity of 1 for Aurora Serverless v1	The minimum capacity setting you can use for an Aurora Serverless v1 cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see Setting the capacity of an Aurora Serverless v1 DB cluster.	April 29, 2019
Aurora Serverless v1 timeout action	You can now specify the action to take when an Aurora Serverless v1 capacity change times out. For more information, see Timeout action for capacity changes.	April 29, 2019
Per-second billing	Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see DB instance billing for Aurora.	April 25, 2019
Sharing Aurora Serverless v1 snapshots across AWS Regions	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across AWS Regions. For information about snapshots of Aurora Serverless v1 DB clusters, see Aurora Serverless v1 and snapshots.	April 17, 2019

Restore MySQL 5.7 backups from Amazon S3	You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.	April 17, 2019
Sharing Aurora Serverless v1 snapshots across regions	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless v1 DB clusters, see Aurora Serverless and snapshots.	April 16, 2019
Aurora proof-of-concept tutorial	You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see Performing an Aurora proof of concept.	April 16, 2019
Aurora Serverless v1 supports restoring from an Amazon S3 backup	You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see Migrating data from MySQL by using an Amazon S3 bucket.	April 16, 2019

New modifiable parameters for Aurora Serverless v1	You can now modify the following DB parameters for an Aurora Serverless v1 cluster: `innodb_file_format`, `innodb_file_per_table`, `innodb_large_prefix`, `innodb_lock_wait_timeout`, `innodb_monitor_disable`, `innodb_monitor_enable`, `innodb_monitor_reset`, `innodb_monitor_reset_all`, `innodb_print_all_deadlocks`, `log_warnings`, `net_read_timeout`, `net_retry_count`, `net_write_timeout`, `sql_mode`, and `tx_isolation`. For more information about configuration parameters for Aurora Serverless v1 clusters, see Aurora Serverless v1 and parameter groups.	April 4, 2019
Aurora PostgreSQL supports db.r5 DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see DB instance class.	April 4, 2019

Aurora PostgreSQL logical replication	You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see Using PostgreSQL logical replication.	March 28, 2019
GTID support for Aurora MySQL 2.04	You can now use replication with the global transaction ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication between Aurora MySQL and an external MySQL 5.7-compatible database. The replication can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see Using GTID-based replication for Aurora MySQL.	March 25, 2019

Uploading Aurora Serverless v1 logs to Amazon CloudWatch	You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless v1 cluster. For more information, see Viewing Aurora Serverless DB clusters. As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see Working with DB parameter groups and DB cluster parameter groups.	February 25, 2019
Aurora MySQL supports db.t3 DB instance classes	You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see DB instance class.	February 25, 2019
Aurora MySQL supports db.r5 DB instance classes	You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see DB instance class.	February 25, 2019

Performance Insights counters for Aurora MySQL	You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see Performance Insights dashboard components.	February 19, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Aurora MySQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora MySQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	February 6, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Aurora PostgreSQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora PostgreSQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	January 24, 2019

Aurora backup billing	You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled` , `SnapshotStorageUsed` , and `BackupRetentionPeriodStorageUsed` to monitor the space usage of your Aurora backups. For more information about how to use CloudWatch metrics, see Overview of monitoring. For more information about how to manage storage for backup data, see Understanding Aurora backup storage usage.	January 3, 2019
Performance Insights counters	You can now add performance counters to your Performance Insights charts. For more information, see Performance Insights dashboard components.	December 6, 2018
Aurora global database	You can now create Aurora global databases. An Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see Working with Amazon Aurora global database.	November 28, 2018

Query plan management in Aurora PostgreSQL	Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see Managing query execution plans for Aurora PostgreSQL.	November 20, 2018
Query editor for Aurora Serverless v1 (beta)	You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see Using the query editor for Aurora Serverless v1.	November 20, 2018
Data API for Aurora Serverless v1 (beta)	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see Using the Data API for Aurora Serverless.	November 20, 2018
TLS support for Aurora Serverless v1	Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see TLS/SSL for Aurora Serverless.	November 19, 2018

Custom endpoints	You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see Amazon Aurora connection management.	November 12, 2018
IAM authentication support in Aurora PostgreSQL	Aurora PostgreSQL now supports IAM authentication. For more information see IAM database authentication.	November 8, 2018
Custom parameter groups for restore and point in time recovery	You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see Restoring from a DB cluster snapshot and Restoring a DB cluster to a specified time.	October 15, 2018
Deletion protection for Aurora DB clusters	When you enable deletion protection for a DB cluster, the database cannot be deleted by any user. For more information, see Deleting a DB cluster.	September 26, 2018

Stop/Start feature Aurora	You can now stop or start an entire Aurora cluster with a single operation. For more information, see Stopping and starting an Aurora cluster.	September 24, 2018
Parallel query feature for Aurora MySQL	Aurora MySQL now offers an option to parallelize I/O work for queries across the Aurora storage infrastructure. This feature speeds up data-intensive analytic queries, which are often the most time-consuming operations in a workload. For more information, see Working with parallel query for Aurora MySQL.	September 20, 2018
New guide	This is the first release of the *Amazon Aurora User Guide.*	August 31, 2018

AWS Glossary

For the latest AWS terminology, see the AWS glossary in the *AWS Glossary Reference*.
