Rehosting your applications in a multi-account architecture on AWS by using VPC interface endpoints

Dipin Jain and Saurabh Shankar, Amazon Web Services

February 2025 ([document history](#))

Many organizations rehost (lift and shift) their applications to AWS from isolated or semi-isolated network environments, including on-premises data centers and other cloud or hybrid infrastructures, by using [AWS Application Migration Service](#). These isolated networks typically do not allow any egress traffic to the public endpoints that are described in the [network requirements for Application Migration Service](#). You can address this limitation by using virtual private cloud (VPC) interface endpoints, as discussed in the AWS Prescriptive Guidance pattern [Connect to Application Migration Service data and control planes over a private network](#).

Many organizations also use a multi-account landing zone (MALZ) architecture for isolation, security, and per-account billing benefits. To enable lift-and-shift migration by using Application Migration Service over a secured network to multiple target AWS accounts, you must create VPC interface endpoints in every target AWS account. This adds to the cost and complexity of managing those resources.

This guide discusses options for centralizing VPC interface endpoints for rehosting your applications in a multi-account architecture on AWS. These options simplify the architecture and reduce costs for such use cases.

Targeted business outcomes

This guide provides solutions for three rehosting use cases. It focuses on reducing costs and operational overhead, and improving security and resource utilization.

Use cases:

- Your applications are mapped to different business units, and you want to migrate them to different AWS target accounts in the same AWS Region to simplify billing and isolation.

The [solution to this scenario](#) involves creating VPC endpoints in a central AWS networking account and using AWS Transit Gateway to connect to target application accounts.

- You want to migrate your applications to different AWS target accounts in multiple AWS Regions to keep your applications close to your users or to facilitate disaster recovery. This is an extension of the first use case.

The [solution to this scenario](#) involves creating VPC endpoints for each AWS Region in an AWS central networking account, and enabling cross-account access by using a peered transit gateway and Amazon Route 53.

- Your applications are mapped to different business units, and you want to migrate them to different AWS target accounts in the same AWS Region for billing and isolation purposes. You also want to use fewer VPCs for Application Migration Service staging, and you want to centrally manage routing for the staging VPCs to reduce costs and administrative overhead.

The [solution to this scenario](#) involves sharing VPC endpoints by using a shared staging area subnet, with AWS Organizations and AWS Resource Access Manager (AWS RAM).

Intended audience

This guide is for migration consultants, application architects, infrastructure architects, and application owners who are looking for solutions for these use cases.

Solution 1: Creating VPC endpoints in a central networking account for a single Region

Use case

Your applications are mapped to different business units and you want to migrate them to different AWS target accounts in the same AWS Region for billing and isolation purposes.

Challenges

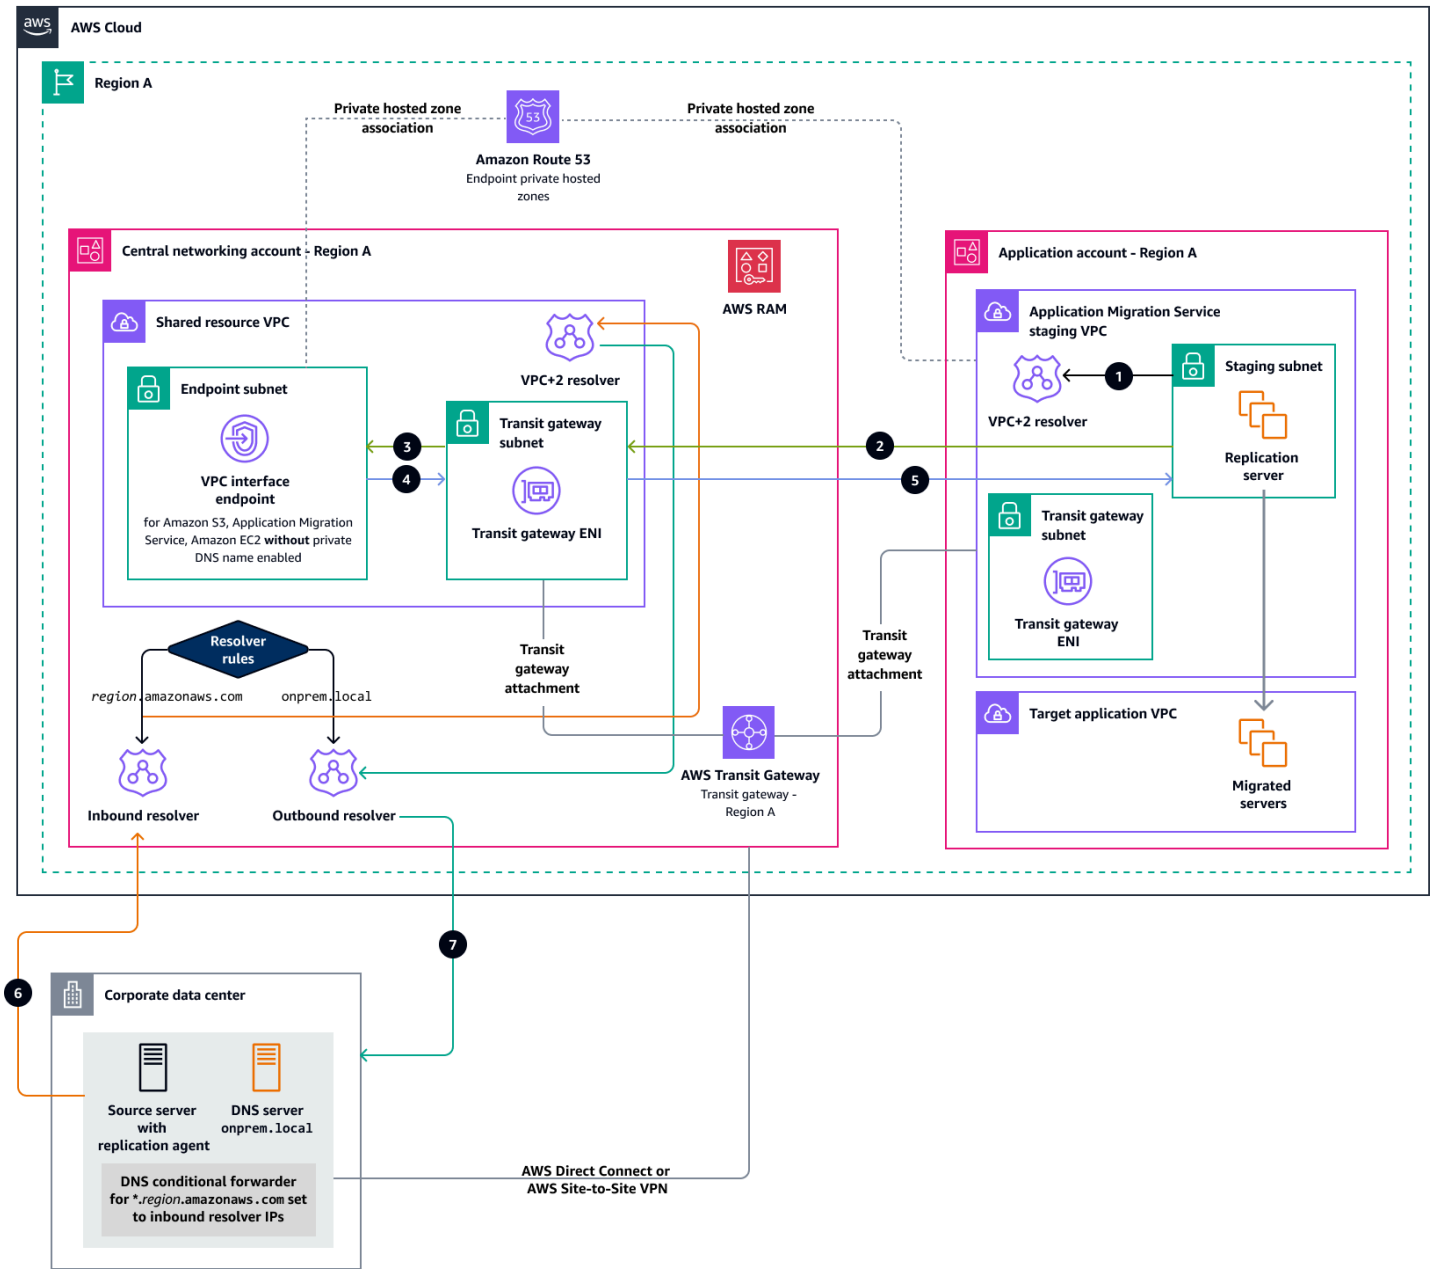

To achieve this over a private network, you would have to create multiple VPC interface endpoints in every target account. This adds to administrative overhead and costs for maintaining endpoints. (See [AWS PrivateLink pricing](#).)

Solution

Create VPC endpoints in a central AWS networking account and use Transit Gateway to connect to target application accounts.

Architecture

The following diagram illustrates the architecture for this solution.

In the diagram, the numbers represent the following traffic flow:

1. The Amazon Elastic Compute Cloud (Amazon EC2) instance or Application Migration Service replication server that needs to connect to Amazon Simple Storage Service (Amazon S3), Application Migration Service, or Amazon EC2 through an interface endpoint that's located in the central networking account VPC first needs to resolve the domain name by querying the VPC+2 resolver. The endpoint private hosted zone is associated with the Application Migration Service staging VPC in the same Region to complete the domain resolution.

Note

For each private hosted zone that you associate with a VPC, the resolver creates a rule and associates it with the VPC. If you associate the private hosted zone with multiple VPCs, the resolver associates the rule with all the VPCs.

2. When the instance knows the private IP to connect to, it sends the traffic to the transit gateway ENI. The traffic is sent to the transit gateway and forwarded to the shared resource VPC, based on the transit gateway route table.
3. The transit gateway ENI in the shared resource VPC forwards the traffic to the corresponding interface endpoint.
4. The VPC endpoint sends the response back to the transit gateway ENI.
5. The traffic is forwarded to the transit gateway. As specified in the transit gateway route table, the traffic is sent to the spoke Application Migration Service staging VPC. The response is sent by the transit gateway ENI to the destination, that is, to the EC2 instance or Application Migration Service replication server.
6. A client application that's located in the corporate data center resolves a domain name in the form `<aws_service>.<aws_region>.amazonaws.com` (for example, `mgn.us-east-1.amazonaws.com`). It sends the query to its preconfigured DNS resolver. The DNS resolver in the corporate data center has a forwarding rule that points any DNS query for `amazonaws.com` domains to the Route 53 Resolver inbound endpoint. Transit Gateway forwards the query to the shared resource VPC, which forwards the DNS query at the Route 53 Resolver inbound endpoint.

The Route 53 Resolver inbound endpoint uses the VPC+2 resolver. The endpoint private hosted zone that's associated with the shared resource VPC holds the DNS records for `amazonaws.com`, so Route 53 Resolver can resolve the query.

7. The Route 53 Resolver outbound endpoint returns the DNS query response to the on-premises client application.

Implementation steps

To set up the architecture shown in the previous diagram, follow these steps:

1. Connect your corporate data center to the central networking account on AWS through AWS Direct Connect or AWS Site-to-Site VPN.
2. In the networking account, use Transit Gateway to provide connectivity between VPCs. The transit gateway is shared between AWS accounts by using AWS RAM, and further connected to the target application account staging subnet through a VPC attachment.

 **Note**

Target AWS accounts do not have to be part of the same AWS organization. For more information, see [Shareable resources](#) in the AWS RAM documentation.

3. Create VPC interface endpoints for Amazon EC2, Application Migration Service, and Amazon S3 in the central network account **without** enabling a private DNS name.

 **Note**

When you create a VPC endpoint to an AWS service, you can enable private DNS. When enabled, the setting creates a managed Route 53 private hosted zone for you. This managed zone resolves the DNS name within a VPC. However, it doesn't work outside the VPC. This is the reason for using private hosted zone sharing and Route 53 Resolver to help get unified name resolution for shared VPC endpoints.

4. Create a private hosted zone for each endpoint (Application Migration Service, Amazon EC2, Amazon S3). For example, for Application Migration Service in the us-east-1 Region:
 - Create a private hosted zone with the domain name `mgn.us-east-1.amazonaws.com`.
 - Create a host record of type A that points the domain name to endpoint IPs.
5. Create Route 53 Resolver inbound and outbound rules to facilitate hybrid DNS resolution, and share the rules with the required AWS account in the same Region.

Solution 2: Creating VPC endpoints in a central networking account for multiple Regions

Use case

You want to migrate your applications or servers to different AWS target accounts in multiple AWS Regions, to keep them close to your users or to enable business continuity in disaster recovery scenarios. This is an extension of the [first use case](#).

Challenges

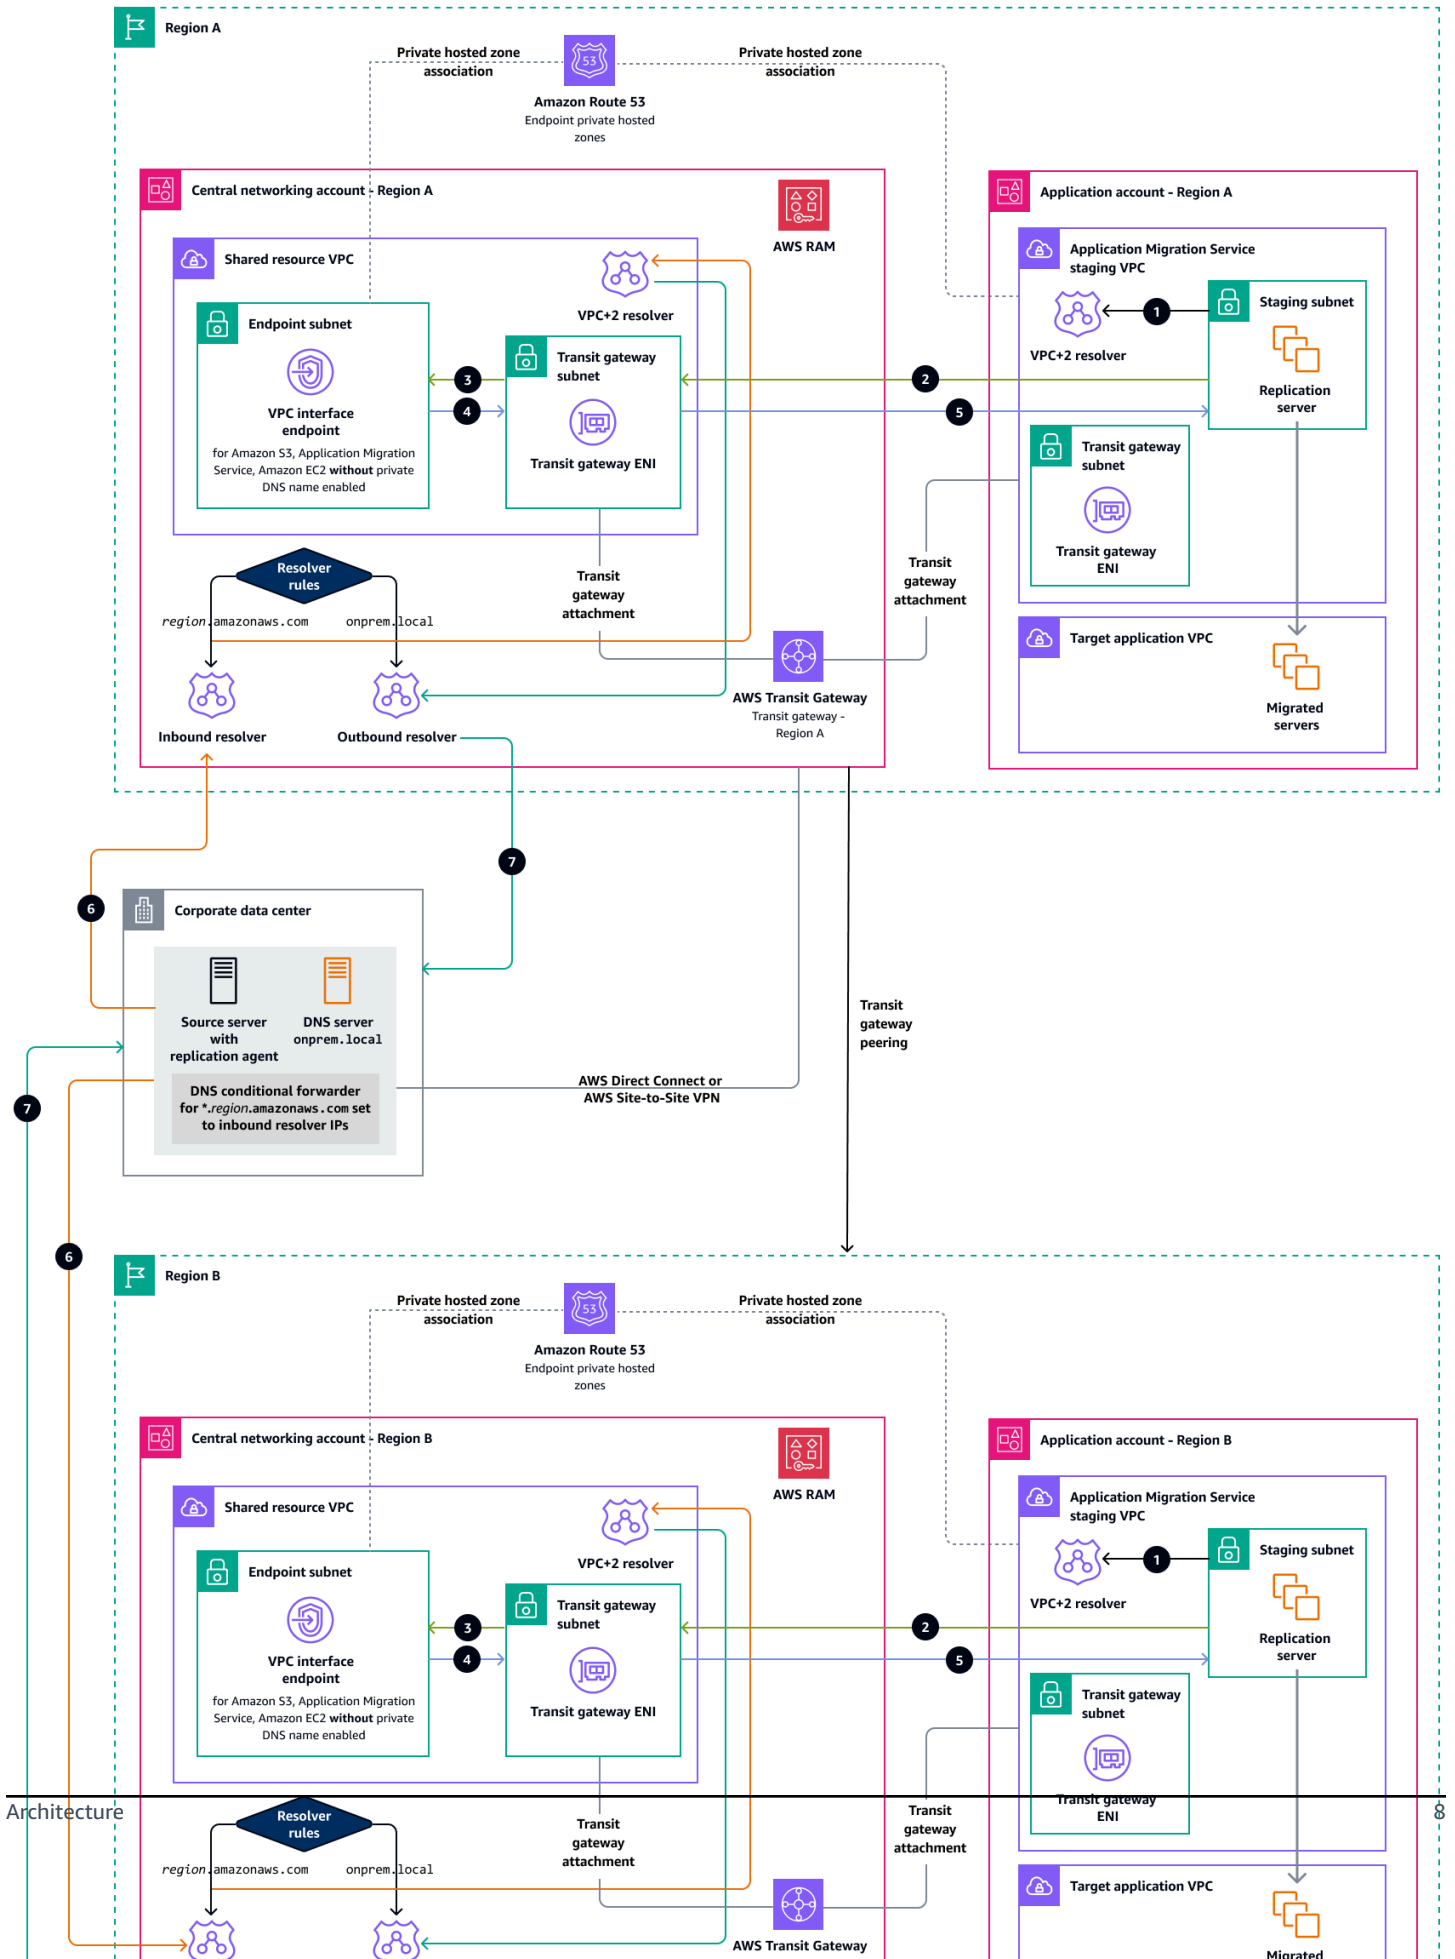

To achieve this over a private network, you would have to create multiple VPC interface endpoints in every target account. This gets even more complex in a multi-Region scenario and adds to administrative overhead and costs for maintaining multiple endpoints. (See [AWS PrivateLink pricing](#).)

Solution

Create VPC endpoints for each Region in a central networking account and enable cross-account access by using a peered transit gateway and Route 53.

Architecture

The following diagram illustrates the architecture for this solution.

The traffic flow is the same as in [solution 1](#), except that the accounts in the two Regions are connected by transit gateway peering.

Implementation steps

1. In the central networking account, create a VPC interface endpoint for each target AWS Region.
2. In the central networking account, create a private hosted zone for each endpoint in each Region, and associate the zone with the target application VPCs in the same Region.
3. In the central networking account, create a transit gateway for each target Region, and share the gateway with target accounts in same Region by using AWS RAM.
4. Connect transit gateways across Regions by using transit gateway peering, and update the transit gateway route tables as required.
5. In the central networking account, create resolver rules for each target Region, and share these rules with target accounts in the same Region by using AWS RAM.

Solution 3: Sharing VPC interface endpoints

Use case

Your applications are mapped to different business units, and you want to migrate them to different AWS target accounts in the same Region for billing and isolation purposes.

Challenges

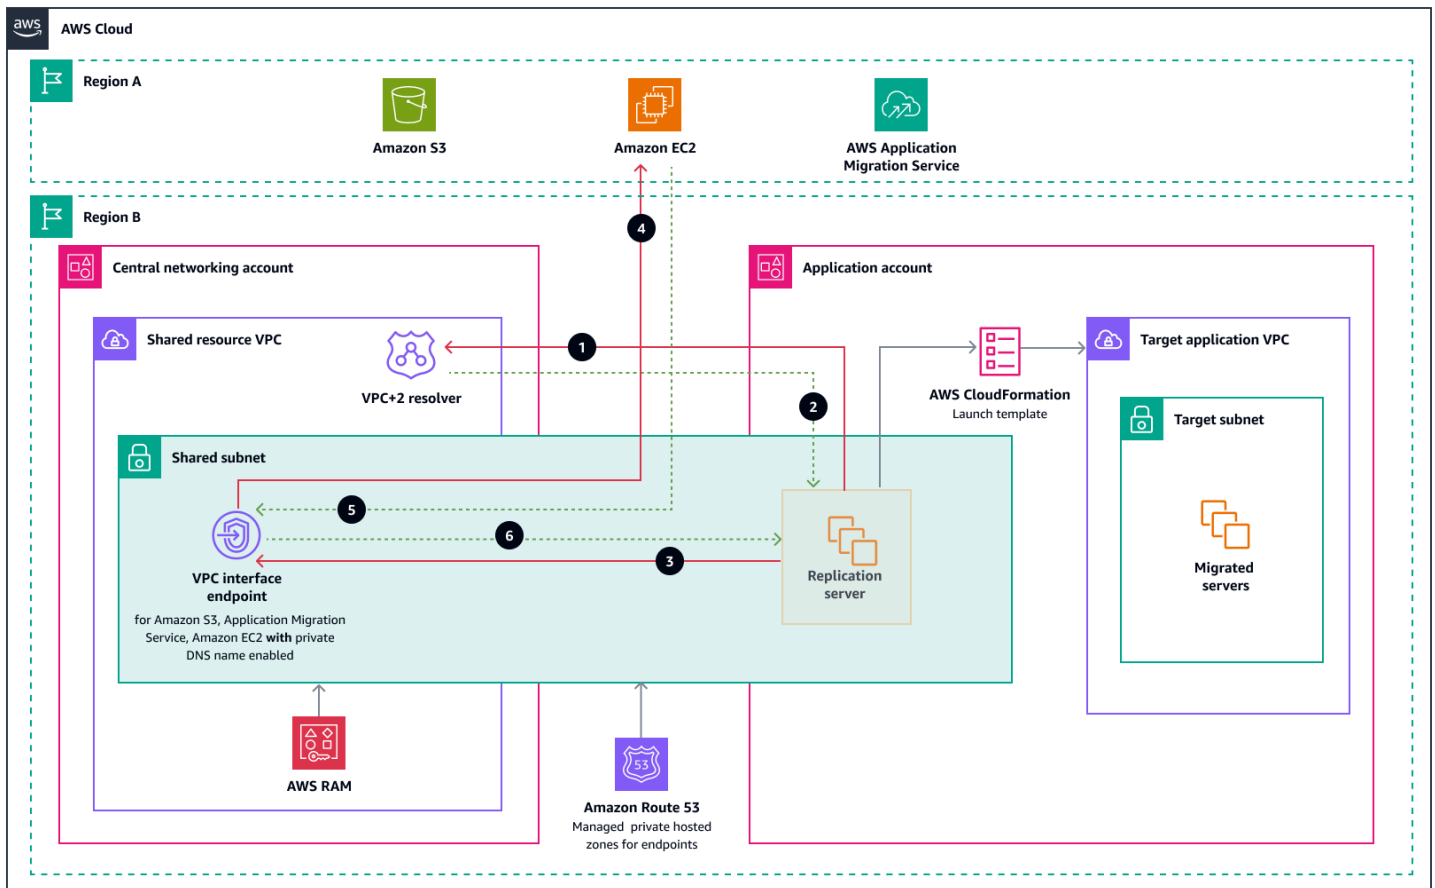

Multiple workload accounts increase both the administrative overhead and the cost of individual VPC interface endpoints in each account. Therefore, you might want to have fewer staging VPCs for Application Migration Service and centrally manage routing for the staging VPCs to reduce costs and administrative overhead.

Solution

Share VPC endpoints by using a shared staging area subnet, AWS Organizations, and AWS RAM. For more information about VPC sharing, see the [Amazon VPC documentation](#).

Architecture

The following diagram illustrates the architecture for this solution.

The diagram illustrates the following traffic flow:

1. The Application Migration Service replication server queries the VPC+2 DNS to resolve the API endpoint for Application Migration Service, Amazon EC2, or Amazon S3.
2. The VPC+2 DNS resolves the private IP of the endpoint with the help of AWS managed private hosted zones and responds to the Application Migration Service replication server.
- 3-6. The replication server uses that IP to connect to the AWS service API through the interface endpoint for the service.

Implementation steps

1. In the central networking account, create the staging VPC and subnet for Application Migration Service.
2. Create endpoints for Application Migration Service, Amazon EC2, or Amazon S3 with private DNS names enabled. This creates an AWS managed private hosted zone and associates it with the staging VPC.

3. Share the staging subnet with target application accounts in the same AWS organization and AWS Region.
4. For hybrid connectivity between AWS and your on-premises data center (not shown in the previous diagram) use Transit Gateway, AWS Direct Connect or AWS Site-to-Site VPN with Route 53 Resolver endpoints, as shown in [solution 1](#) and [solution 2](#).

Limitations

- The AWS accounts for the participant VPCs and the owner VPC have to be part of the same organization in AWS Organizations.
- For a list of shareable resources, see the [Amazon VPC documentation](#).
- For VPC sharing limitations, see the [Amazon VPC documentation](#).

Design considerations

- To reduce your operational overhead, create a resource once, and then use AWS RAM to share that resource with other accounts. This eliminates the need to provision duplicate resources in every account and reduces operational overhead.
- Simplify security management for your shared resources by using a single set of policies and permissions. If you create duplicate resources in your separate accounts, you have to implement identical policies and permissions and keep them synchronized across all accounts. Instead, you can manage all users who share an AWS RAM resource through a single set of policies and permissions. AWS RAM offers a consistent experience for sharing different types of AWS resources.
- Provide visibility and auditability. View the usage details for your shared resources by integrating AWS RAM with Amazon CloudWatch and AWS CloudTrail. For more information, see [Monitoring AWS RAM using EventBridge](#) and [Logging AWS RAM API calls with AWS CloudTrail](#) in the AWS RAM documentation.

FAQ

Q: Who can I share resources with?

A: You can share resources with any AWS account. If you are part of an organization in AWS Organizations and sharing within your organization is enabled, you can also share resources with organizational units (OUs) or with your entire organization. For supported resource types, you can also share resources with AWS Identity and Access Management (IAM) roles and IAM users. If you share resources with accounts that are outside your organization, those accounts receive an invitation to join the resource share. After they accept the invitation, they can start using the shared resources.

Q: Will I incur any charges for sharing my resources with other AWS accounts?

A: No. You can share resources at no additional cost.

Q: Can I stop sharing a resource?

A: Yes. To stop sharing a resource, remove it from the resource share or delete the resource share.

Q: How can I ensure security in AWS RAM?

A: Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud. For more information, see [Security in AWS RAM](#) in the AWS RAM documentation.

Best practices

- Avoid single points of failure. For VPC endpoints and Route 53 Resolver endpoints, use two or more Availability Zones for high availability.
- Do not use Route 53 Resolver endpoints to forward DNS queries between VPCs. We strongly recommend that you use the Amazon DNS Server (.2 resolver) as the DNS resolver for all instances inside Amazon EC2. This resolver provides the highest level of availability and scalability with the lowest latency.
- For additional best practices, see [Best practices for Resolver](#) in the Route 53 documentation.

The following are commonly used terms in strategies, guides, and patterns provided by AWS Prescriptive Guidance. To suggest entries, please use the **Provide feedback** link at the end of the glossary.

Numbers

7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- **Refactor/re-architect** – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.
- **Replatform (lift and reshape)** – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.
- **Repurchase (drop and shop)** – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.
- **Rehost (lift and shift)** – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.
- **Relocate (hypervisor-level lift and shift)** – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. You migrate servers from an on-premises platform to a cloud service for the same platform. Example: Migrate a Microsoft Hyper-V application to AWS.
- **Retain (revisit)** – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later time, and legacy applications that you want to retain, because there's no business justification for migrating them.

- Retire – Decommission or remove applications that are no longer needed in your source environment.

active-active migration

A database migration method in which the source and target databases are kept in sync (by using a bidirectional replication tool or dual write operations), and both databases handle transactions from connecting applications during migration. This method supports migration in small, controlled batches instead of requiring a one-time cutover. It's more flexible but requires more work than [active-passive migration](#).

A single CI/CD pipeline can use multiple repositories.

An information security approach in which a series of security mechanisms and controls are thoughtfully layered throughout a computer network to protect the confidentiality, integrity, and availability of the network and the data within. These controls are a second line of defense, alerting you to security events that bypassed the preventative controls in place. For more information, see [Detective controls](#) in *Implementing security controls on AWS*.

development value stream mapping (DVSM)

A process used to identify and prioritize constraints that adversely affect speed and quality in a software development lifecycle. DVSM extends the value stream mapping process originally designed for lean manufacturing practices. security response automation

A predefined and programmed action that is designed to automatically respond to or remediate a security event. These automations serve as [detective](#) or [responsive](#) security controls that help you implement AWS security best practices. Examples of automated response actions include modifying a VPC security group, patching an Amazon EC2 instance, or rotating credentials.

Encryption of data at its destination, by the AWS service that receives it.

service control policy (SCP)

A policy that provides centralized control over permissions for all accounts in an organization in AWS Organizations. SCPs define guardrails or set limits on actions that an administrator can delegate to users or roles. You can use SCPs as allow lists or deny lists, to specify which services or actions are permitted or prohibited. For more information, see [Service control policies](#) in the AWS Organizations documentation.

SLO

See [service-level objective](#).

split-and-seed model

A pattern for scaling and accelerating modernization projects. As new features and product releases are defined, the core team splits up to create new product teams. This helps scale your organization's capabilities and services, improves developer productivity, and supports rapid

innovation. For more information, see [Phased approach to modernizing applications in the AWS Cloud](#).

SPOF

See [single point of failure](#).

star schema

A database organizational structure that uses one large fact table to store transactional or measured data and uses one or more smaller dimensional tables to store data attributes. This structure is designed for use in a [data warehouse](#) or for business intelligence purposes.

strangler fig pattern

An approach to modernizing monolithic systems by incrementally rewriting and replacing system functionality until the legacy system can be decommissioned. This pattern uses the analogy of a fig vine that grows into an established tree and eventually overcomes and replaces its host. The pattern was [introduced by Martin Fowler](#) as a way to manage risk when rewriting monolithic systems. For an example of how to apply this pattern, see [Modernizing legacy Microsoft ASP.NET \(ASMX\) web services incrementally by using containers and Amazon API Gateway](#).

Testing a system in a way that simulates user interactions to detect potential issues or to monitor performance. You can use [Amazon CloudWatch Synthetics](#) to create these tests.

system prompt

A technique for providing context, instructions, or guidelines to an [LLM](#) to direct its behavior. System prompts help set context and establish rules for interactions with users.

T

tags

Key-value pairs that act as metadata for organizing your AWS resources. Tags can help you manage, identify, organize, search for, and filter resources. For more information, see [Tagging your AWS resources](#).

target variable

The value that you are trying to predict in supervised ML. This is also referred to as an *outcome variable*. For example, in a manufacturing setting the target variable could be a product defect.

task list

A tool that is used to track progress through a runbook. A task list contains an overview of the runbook and a list of general tasks to be completed. For each general task, it includes the estimated amount of time required, the owner, and the progress.

test environment

See [environment](#).

training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don't know the target.

transit gateway

A network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information, see [What is a transit gateway](#) in the AWS Transit Gateway documentation.

trunk-based workflow

An approach in which developers build and test features locally in a feature branch and then merge those changes into the main branch. The main branch is then built to the development, preproduction, and production environments, sequentially.

trusted access

Granting permissions to a service that you specify to perform tasks in your organization in AWS Organizations and in its accounts on your behalf. The trusted service creates a service-linked role in each account, when that role is needed, to perform management tasks for you. For more information, see [Using AWS Organizations with other AWS services](#) in the AWS Organizations documentation.

tuning

To change aspects of your training process to improve the ML model's accuracy. For example, you can train the ML model by generating a labeling set, adding labels, and then repeating these steps several times under different settings to optimize the model.

two-pizza team

A small DevOps team that you can feed with two pizzas. A two-pizza team size ensures the best possible opportunity for collaboration in software development.

U

uncertainty

A concept that refers to imprecise, incomplete, or unknown information that can undermine the reliability of predictive ML models. There are two types of uncertainty: *Epistemic uncertainty* is caused by limited, incomplete data, whereas *aleatoric uncertainty* is caused by the noise and randomness inherent in the data. For more information, see the [Quantifying uncertainty in deep learning systems](#) guide.

undifferentiated tasks

Also known as *heavy lifting*, work that is necessary to create and operate an application but that doesn't provide direct value to the end user or provide competitive advantage. Examples of undifferentiated tasks include procurement, maintenance, and capacity planning.

upper environments

See [environment](#).

V

vulnerability

A software or hardware flaw that compromises the security of the system.

W

warm cache

A buffer cache that contains current, relevant data that is frequently accessed. The database instance can read from the buffer cache, which is faster than reading from the main memory or disk.

warm data

Data that is infrequently accessed. When querying this kind of data, moderately slow queries are typically acceptable.

A collection of resources and code that delivers business value, such as a customer-facing application or backend process.

workstream

Functional groups in a migration project that are responsible for a specific set of tasks. Each workstream is independent but supports the other workstreams in the project. For example, the portfolio workstream is responsible for prioritizing applications, wave planning, and collecting migration metadata. The portfolio workstream delivers these assets to the migration workstream, which then migrates the servers and applications.

WORM

See [write once, read many](#).

WQF

See [AWS Workload Qualification Framework](#).

write once, read many (WORM)

A storage model that writes data a single time and prevents the data from being deleted or modified. Authorized users can read the data as many times as needed, but they cannot change it. This data storage infrastructure is considered [immutable](#).

Z

zero-day exploit

An attack, typically malware, that takes advantage of a [zero-day vulnerability](#).

zero-day vulnerability

An unmitigated flaw or vulnerability in a production system. Threat actors can use this type of vulnerability to attack the system. Developers frequently become aware of the vulnerability as a result of the attack.

zero-shot prompting

Providing an [LLM](#) with instructions for performing a task but no examples (*shots*) that can help guide it. The LLM must use its pre-trained knowledge to handle the task. The effectiveness of zero-shot prompting depends on the complexity of the task and the quality of the prompt. See also [few-shot prompting](#).

zombie application

An application that has an average CPU and memory usage below 5 percent. In a migration project, it is common to retire these applications.
