Extract sensor data and apply object detection with custom business logic

Publication date: *November 2023* (last update: [May 2024](#))

Scene Intelligence with Rosbag on AWS provides an end-to-end solution for extracting sensor data from [rosbag](#) files generated from autonomous driving use cases. This solution guides users through a sample use case to demonstrate how the processing occurs and where custom logic can be applied to the extracted data. You can use this solution to:

- Stage sample rosbag files
- Extract rosbag sensor data such as metadata and images
- Apply object detection ([YOLOv5](#)) and lane detection ([LaneDet](#)) models to extracted images
- Apply scene detection business logic and store the output in an indexable fashion, using [Amazon DynamoDB](#) and [Amazon OpenSearch Service](#)

This implementation guide provides an overview of the Scene Intelligence with Rosbag on AWS solution, its reference architecture and components, considerations for planning the deployment, and configuration steps for deploying the solution to the Amazon Web Services (AWS) Cloud.

The intended audience for using this solution's features and capabilities in their environment includes solution architects, business decision makers, DevOps engineers, data scientists, and cloud professionals.

Use this navigation table to quickly find answers to these questions:

If you want to . . .	Read . . .
Know the cost for running this solution. The estimated cost for running this solution in the US East (N. Virginia) Region is USD \$605.13 per month for AWS resources.	Cost
Understand the security considerations for this solution.	Security

If you want to . . .	Read . . .
Know how to plan for quotas for this solution.	Quotas
Know which AWS Regions support this solution.	Supported AWS Regions
View or download the AWS CloudFormation template included in this solution to automatically deploy the infrastructure resources (the "stack") for this solution.	AWS CloudFormation template
Access the source code and optionally use the AWS Cloud Development Kit (AWS CDK) to deploy the solution.	GitHub repository

Features and benefits

The solution provides the following features:

Extract rosbag data

You can use this solution to store rosbag files in [Amazon Simple Storage Service](#) (Amazon S3) and invoke [Directed Acyclic Graphs](#) (DAGs) with [Amazon Managed Workflows for Apache Airflow](#) (Amazon MWAA) to extract and process the data. With the data extracted and processed, you can more easily review and analyze your data.

Customizable end-to-end

You can determine which sensors to process, change the machine learning (ML) models used for processing, and bring your own DAGs for processing.

Indexable metadata

Business data output that the solution writes to DynamoDB and is automatically available in OpenSearch Service, ready to be queried without user management.

Integration with Service Catalog AppRegistry and Application Manager, a capability of AWS Systems Manager

This solution includes a [Service Catalog AppRegistry](#) resource to register the solution's CloudFormation template and its underlying resources as an application in both AppRegistry and [Application Manager](#). With this integration, you can centrally manage the solution's resources and enable application search, reporting, and management actions.

Use cases

Extract rosbag data

You can use this solution to extract the structured data (metadata) and unstructured data, such as images, from defined topics in Robot Operating System (ROS)1 rosbag files. The topics in this solution match the same that rosbag provides, and you can change them to fit your custom topics. The solution writes all topic data to Amazon S3, including images as .png files and metadata as Apache Parquet.

Apply business logic

You can apply custom business logic to the extracted data by using an Apache Spark script. Modify the processing DAG to match your rosbag, apply your own logic, or use the provided DAG and scripts.

Search for anomalies

The processing logic output applied to the extracted data is written to DynamoDB and OpenSearch Service. You can query the metadata output from an OpenSearch Service dashboard or with an OpenSearch service application programming interface (API) to locate a section of the rosbag file for inspection.

Concepts and definitions

This section describes key concepts and defines terminology specific to this solution:

AV/ADAS

Autonomous Vehicle/Advanced Driver-Assistance System. Developing and deploying AV/ADASs requires scalable compute, storage, networking, analytics, and deep learning frameworks.

DAG

Directed Acyclic Graph. Workflows in Amazon MWAA are authored as DAGs using Python.

drive

Logical grouping of data, such as Test Car 1 stores its rosbag file on Drive 1.

lane detection (LaneDet)

A specific object detection model to identify automotive roads within images.

object detection

Refers to identifying objects within an image pulled from the rosbag file. Based on the [COCO dataset](#) for object detection, this term implies the detection of recognized objects such as street lights, stop signs, and people.

ROS

Robot Operating System. The ROS is a set of software libraries and tools that help you build robot applications.

rosbag

A ROS archive file containing sensor data, meant for playback and logging.

scene detection

See **object detection**.

YOLO

You Only Look Once, a PyTorch object detection model.

Note

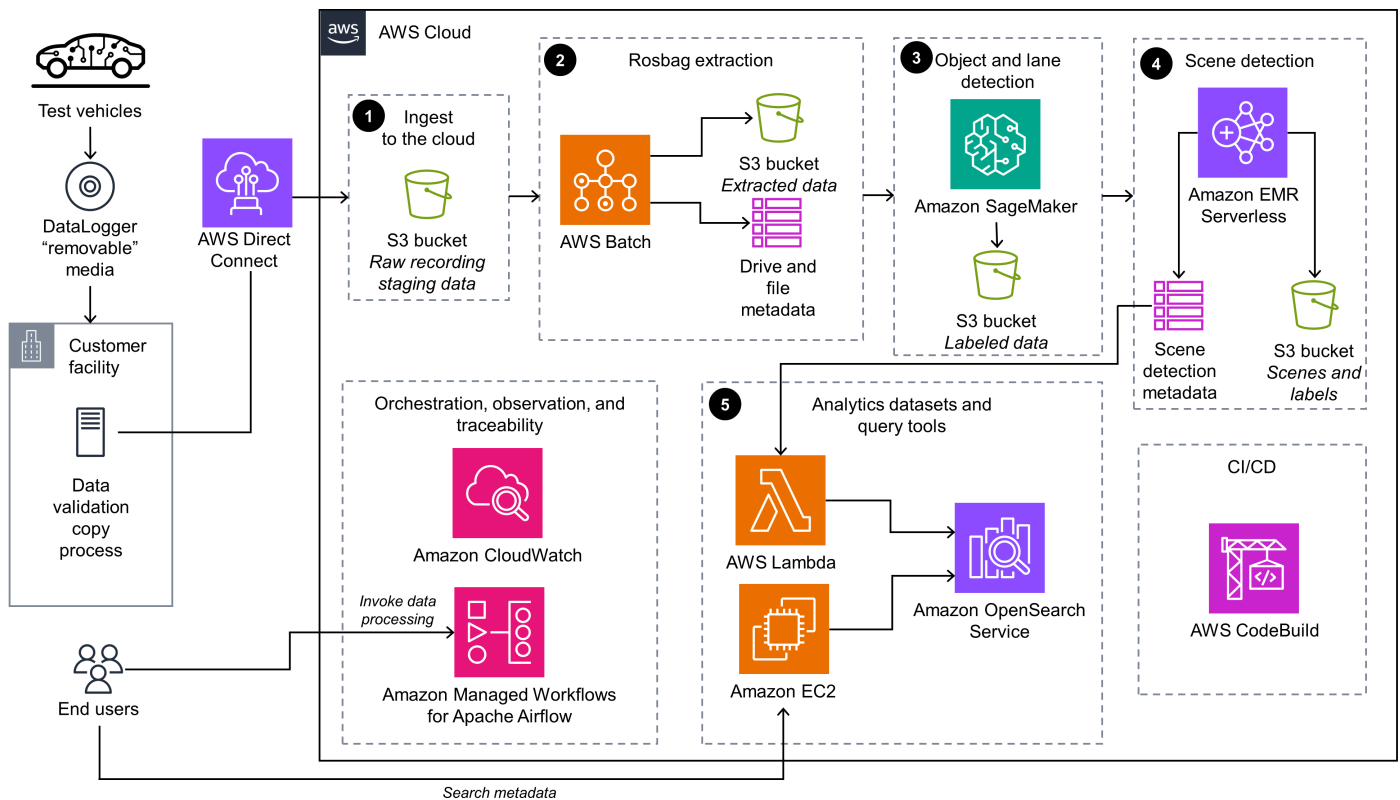

For a general reference of AWS terms, see the [AWS Glossary](#).

Architecture overview

This section provides a reference implementation architecture diagram for the components deployed with this solution.

Architecture diagram

Deploying this solution with the default parameters deploys the following components in your AWS account.

Scene Intelligence with Rosbag on AWS architecture

The high-level process flow for the solution components deployed with the CloudFormation template is as follows:

1. The AV uploads the rosbag file to [Amazon S3](#). The end user invokes the workflow to start processing through [Amazon MWAA](#) and a DAG. See [Invoke the DAG](#) for instructions on this process.
2. [AWS Batch](#) performs the following actions:

- a. Pulls the rosbag file from Amazon S3
 - b. Parses and extracts the sensor and image data
 - c. Writes this data to another S3 bucket
3. [Amazon SageMaker](#) applies object detection and LaneDet models to the extracted data. SageMaker then writes the data and labels to another S3 bucket.
 4. [Amazon EMR Serverless](#) (with an Apache Spark job) applies business logic to the data and labels in Amazon S3. This generates metadata related to the object detection and LaneDet. Amazon EMR Serverless then writes the metadata to [DynamoDB](#) and another S3 bucket.
 5. An [AWS Lambda](#) function publishes new incoming DynamoDB data (metadata) to the [OpenSearch Service](#) cluster. The end user accesses the OpenSearch Service cluster through a proxy on [Amazon Elastic Compute Cloud](#) (Amazon EC2) to submit queries against the metadata.

AWS Well-Architected design considerations

This solution uses the best practices from the [AWS Well-Architected Framework](#), which helps customers design and operate reliable, secure, efficient, and cost-effective workloads in the cloud.

This section describes how the design principles and best practices of the Well-Architected Framework benefit this solution.

Operational excellence

This section describes how we architected this solution using the principles and best practices of the [operational excellence pillar](#).

- All Lambda functions send logging output to [Amazon CloudWatch](#).
- Alarms from AWS services included in this solution are stored in CloudWatch to provide observability into the infrastructure.
- You can review past runtime outcomes for Amazon MWAA, AWS Batch, and EMR Serverless.

Security

This section describes how we architected this solution using the principles and best practices of the [security pillar](#).

- All inter-service communications use [AWS Identity and Access Management](#) (IAM) roles.

- All roles used by the solution follow least-privilege access. That is, they only contain the minimum permissions required so that the service can function properly.
- All S3 buckets have default encryption at rest activated.
- Access to data storage buckets is logged into a separate bucket.
- Database metadata is encrypted using [AWS Key Management Service](#) (AWS KMS) keys.

Reliability

This section describes how we architected this solution using the principles and best practices of the [reliability pillar](#).

- The solution uses AWS serverless services wherever possible to ensure high availability and recovery from service failure.
- All compute processing uses Lambda functions wherever possible.
- Data is stored in S3 buckets and DynamoDB tables, so it persists in multiple Availability Zones by default.
- The solution uses Amazon MWAA to orchestrate the workflow and provides the run history and ability to retry the failed process(es) and re-invoke the workflow.
- All custom code uses [AWS Software Development Kit](#) (AWS SDK) and benefits from automatic retries and back-off for API calls.

Performance efficiency

This section describes how we architected this solution using the principles and best practices of the [performance efficiency pillar](#).

- The solution uses serverless compute and data resources throughout the architecture.
- You can launch the solution in any Region that supports AWS services used in this solution, such as Amazon MWAA, Lambda, Amazon S3, SageMaker, EMR Serverless.
- The solution is automatically tested and deployed every day. The solution is also reviewed by solution architects and subject matter experts for areas to experiment and improve.

Cost optimization

This section describes how we architected this solution using the principles and best practices of the [cost optimization pillar](#).

- This solution uses Lambda functions, AWS Batch, EMR Serverless, and SageMaker processing jobs for most compute needs.
- You can choose to run the solution on-demand or at an interval that you choose.

Sustainability

This section describes how we architected this solution using the principles and best practices of the [sustainability pillar](#).

- This solution uses serverless resources for compute and data storage.
- Most data storage is maintained in an S3 bucket or DynamoDB table that you can remove easily.

Architecture details

This section describes the components and AWS services that make up this solution and the architecture details on how these components work together.

Store and stage data

This solution uses Amazon S3 to store the original raw rosbag data, also referred to as staged data. The solution processes the rosbag files and stores the extracted data, both structured and unstructured, in Amazon S3. The unstructured data is stored as .png images, and the structured data is stored as Apache Parquet data.

Extract rosbag data

The solution processes the rosbag files by using an Amazon MWAA DAG that invokes several AWS services for processing. The solution performs the following actions:

- Extracts rosbag data by using AWS Batch and custom docker images stored in private Amazon ECR repositories
- Opens the rosbag files and extracts their sensor data
- Writes the extracted data back to Amazon S3 as either images (.png files) or Apache Parquet data

Detect objects and label

The next phase of the Amazon MWAA DAG applies object detection and LaneDet ML processing to the extracted images by using SageMaker processing jobs. The processing jobs use custom Docker images stored in private Amazon ECR repositories. The solution writes the resulting output to Amazon S3.

Apply business logic to extracted data

The final stage of the Amazon MWAA DAG applies custom business logic to the extracted metadata (Apache Parquet) and the resulting output from the object detection and LaneDet processes. The business logic leverages Apache Spark and runs on Amazon EMR Serverless to process the data. The solution writes the resulting metadata output from the Apache Spark job to both Amazon

S3 and DynamoDB. When the solution writes the metadata to DynamoDB, it invokes a Lambda function that forwards the data to OpenSearch Service for indexing.

Search metadata output

After the solution writes the data to OpenSearch Service, you can query the data with [OpenSearch Dashboards](#). The solution provides an Amazon EC2 instance that acts as a proxy for secure communication. This proxy only allows [AWS Systems Manager](#) tunneling for port-forwarding to enable secure communication.

AWS services in this solution

AWS service	Description
AWS Batch	Core. The solution uses AWS Batch processing for extracting Apache Parquet and PNG files.
Amazon DynamoDB	Core. This solution creates a DynamoDB table for tracking the batch of rosbag files, and another DynamoDB table for tracking the metadata that is generated after identifying lanes and objects from drive files. This solution uses the second DynamoDB table for downstream consuming and querying purposes.
Amazon EMR Serverless	Core. The solution loads outputs from object detection and LaneDet into data frames and integration with the Parquet data by using Amazon EMR Serverless. This provides metadata for querying.
Amazon MWAA	Core. Amazon MWAA orchestrates the workflow of uploading the rosbag files, extracting images and lanes from the files using open source YOLO model, and writing the required metadata to DynamoDB table.

AWS service	Description
Amazon OpenSearch Service	Core. This solution creates an OpenSearch Service cluster for advanced querying purposes. This cluster uses the metadata from DynamoDB.
Amazon S3	Core. The solution stages all rosbag input files in a source S3 bucket for raw data, and the intermediate artifacts (such as Apache Parquet, PNG, and JSON files) in an intermediate S3 bucket for staged data.
Amazon SageMaker	Core. The solution runs object detection and LaneDet jobs by using SageMaker processing jobs.
AWS CodeBuild	Supporting. AWS CodeBuild manages module deployments for this solution.
Amazon EC2	Supporting. A micro Amazon EC2 instance acts as a secure proxy to the OpenSearch Dashboard.
Amazon ECR	Supporting. The solution builds and stores container images related to the <code>ros-parquet</code> , <code>ros-png</code> , <code>lane-detection</code> , and <code>object-detection</code> applications in internal Amazon ECR repositories.
AWS IAM	Supporting. This solution creates IAM roles for all the AWS services that require permissions to communicate with other AWS APIs. This solution uses least-privileged IAM policies.
AWS Lambda	Supporting. This solution uses a Lambda function to load the data from the DynamoDB table into an OpenSearch Service cluster.

AWS service	Description
AWS Systems Manager	Supporting. The solution allows Systems Manger tunneling for port forwarding to an Amazon EC2 instance in a private Amazon VPC subnet. This allows secure access to the OpenSearch Dashboard.

Plan your deployment

This section describes the [cost](#), [security](#), [Regions](#), and other considerations prior to deploying the solution.

Cost

You are responsible for the cost of the AWS services used while running this solution. As of this revision, the cost for running this solution with the default settings in the default US East (N. Virginia) Region is approximately **\$605.13 per month**.

See the pricing webpage for each AWS service used in this solution.

We recommend creating a [budget](#) through [AWS Cost Explorer](#) to help manage costs. Prices are subject to change. For full details, see the pricing webpage for each [AWS service used in this solution](#).

Sample cost table

The following table provides a sample cost breakdown for deploying this solution with the default parameters in the US East (N. Virginia) Region for one month.

AWS service	Dimensions	Cost [USD]
Amazon MWAA	31 days × 24 hours/day (1 worker, 2 schedulers)	\$355.00
Amazon EMR Serverless	2 vCPU × vCPU-hours rate (\$0.052624) × job runtime in hour (8 min/60 min) 4GB memory × GB-hours rate(\$0.0057785) × job runtime in hour (8 min/60 min)	\$0.016

AWS service	Dimensions	Cost [USD]
Amazon OpenSearch Service	31 days × 24 hours/day (1 node with 50 GB storage and no dedicated master)	\$128.00
Amazon EC2	Includes AWS Batch jobs processing (only when invoked) and Amazon EC2 proxy (31 days × 24 hours/day) for querying OpenSearch Service	\$49.00
AWS Lambda	AWS Free Tier	\$0.00
Systems Manager Parameter Store		\$0.05
AWS CodeBuild	Invoked during deploying and destroying the solution	\$25.00
Amazon CloudWatch		\$20.00
Amazon VPC		\$19.00
Amazon S3		\$6.20
Amazon ECR		\$1.60
AWS KMS		\$1.20
Amazon SageMaker	LaneDet and object detection	\$0.06
Amazon DynamoDB	AWS Free Tier	\$0.00
Total:		\$605.13 [USD] / month

Security

When you build systems on AWS infrastructure, security responsibilities are shared between you and AWS. This [shared responsibility model](#) reduces your operational burden because AWS operates, manages, and controls the components including the host operating system, the virtualization layer, and the physical security of the facilities in which the services operate. For more information about AWS security, visit [AWS Cloud Security](#).

IAM roles

IAM roles allow this solution to assign granular access policies and permissions to services and users on the AWS Cloud. This solution creates IAM roles that grant the solution's Lambda functions access to manage Regional resources.

VPC security groups

The solution creates security groups designed to control and isolate network traffic between the Lambda functions, Amazon EC2 instances, and remote virtual private network (VPN) endpoints. We recommend that you review the security groups and further restrict access as needed once the deployment is up and running.

Supported AWS Regions

This solution uses the Amazon MWAA service, which is not currently available in all AWS Regions. For the most current availability of AWS services by Region, see the [AWS Regional Services List](#).

Scene Intelligence with Rosbag on AWS is available in the following AWS Regions:

Region name	
US East (Ohio)	Europe (Frankfurt)
US East (N. Virginia)	Europe (Ireland)
US West (Oregon)	Europe (London)
Asia Pacific (Mumbai)	Europe (Paris)
Asia Pacific (Singapore)	Europe (Stockholm)

Region name	
Asia Pacific (Sydney)	South America (São Paulo)
Asia Pacific (Tokyo)	

Quotas

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account.

Quotas for AWS services in this solution

Make sure you have sufficient quota for each of the [services implemented in this solution](#). For more information, see [AWS service quotas](#).

Use the following links to go to the page for that service. To view the service quotas for all AWS services in the documentation without switching pages, view the information in the [Service endpoints and quotas](#) page in the PDF instead.

AWS CodeBuild quotas

AWS CodeBuild can have a quota limit set for concurrently running builds. This solution has a limit of five concurrently running builds to reduce the deployment time. If this limit isn't raised, it won't block the deployment, but you might experience delays. See [AWS CodeBuild quotas](#) for more information.

Deploy the solution

This solution uses [CloudFormation templates and stacks](#) to automate its deployment. The CloudFormation templates specify the AWS resources included in this solution and their properties. The CloudFormation stack provisions the resources that are described in the templates.

Deployment process overview

Follow the step-by-step instructions in this section to configure and deploy the solution into your account.

Before you launch the solution, review the [cost](#), [architecture](#), [network security](#), and other considerations discussed earlier in this guide.

Time to deploy: Approximately 100–120 minutes

AWS CloudFormation template for deployment

You can download the CloudFormation template for this solution before deploying it. This solution uses a separate CloudFormation template to handle the deployment workflow.

[View template](#)

scene-intelligence-with-rosvbag-on-aws-create.template - Use this template to launch the solution and all associated components. The default configuration deploys the core and supporting services found in the [AWS services in this solution](#) section orchestrated by an open source GitOps library called `seedfarmer`, but you can customize the template to meet your specific needs.

Note

CloudFormation resources are created from AWS Cloud Development Kit (AWS CDK) constructs.

Prerequisites for deployment

This AWS CloudFormation template deploys Scene Intelligence with Rosbag on AWS in the AWS Cloud. You must meet the following prerequisites before launching the stack:

- Administrative permissions, or permissions sufficient to create and configure the AWS services used by these stacks.

Launch the deployment stack

Follow the step-by-step instructions in this section to configure and deploy the solution into your account.

Time to deploy: Approximately 100–120 minutes

1. Sign in to the [AWS Management Console](#) and select the button to launch the scene-intelligence-with-rosvbag-on-aws-create.template CloudFormation template.

Launch solution

2. The template launches in the US East (N. Virginia) Region by default. To launch the solution in a different AWS Region, use the Region selector in the console navigation bar.

Note

This solution uses the Amazon MWAA service, which is not currently available in all AWS Regions. You must launch this solution in a Region where Amazon MWAA is available. For the most current availability by Region, see the [AWS Regional Services List](#).

3. On the **Create stack** page, verify that the correct template URL is in the **Amazon S3 URL** text box and choose **Next**.
4. On the **Specify stack details** page, assign a name to your solution stack. For information about naming character limitations, see [IAM and AWS STS quotas](#) in the *AWS Identity and Access Management User Guide*.
5. Select **Next**.
6. On the **Configure stack options** page, choose **Next** after reviewing the settings.
7. On the **Review and create** page, review and confirm the settings. Select the box acknowledging that the template will create IAM resources.
8. Choose **Submit** to deploy the stack.

You can view the status of the stack in the AWS CloudFormation console in the **Status** column. You should receive a CREATE_COMPLETE status in approximately 100–120 minutes.

Monitor the solution with AppRegistry

The solution includes a Service Catalog AppRegistry resource to register the CloudFormation template and underlying resources as an application in both Service Catalog AppRegistry and AWS Systems Manager Application Manager.

AWS Systems Manager Application Manager gives you an application-level view into this solution and its resources so that you can:

- Monitor its resources, costs for the deployed resources across stacks and AWS accounts, and logs associated with this solution from a central location.
- View operations data for the resources of this solution in the context of an application. For example, deployment status, CloudWatch alarms, resource configurations, and operational issues.

The following figure depicts an example of the application view for the solution stack in Application Manager.

The screenshot displays the AWS Systems Manager Application Manager console. On the left, a sidebar shows a list of components under 'Components (2)', including 'AWS-Systems-Manager-Application-Manager' and 'AWS-Systems-Manager-A'. The main content area is titled 'AWS-Systems-Manager-Application-Manager' and features a 'Start runbook' button. Below the title is the 'Application information' section, which includes a 'View in AppRegistry' link. The application type is 'AWS-AppRegistry', the name is 'AWS-Systems-Manager-Application-Manager', and application monitoring is 'Not enabled'. A description states: 'Service Catalog application to track and manage all your resources for the solution'. A navigation bar below the application information includes tabs for Overview, Resources, Instances, Compliance, Monitoring, OpsItems, Logs, Runbooks, and Cost. The 'Overview' tab is active, showing 'Insights and Alarms' and 'Cost' sections. The 'Insights and Alarms' section includes a 'View all' button and a note to monitor application health with Amazon CloudWatch. The 'Cost' section includes a 'View all' button and a note to view resource costs per application using AWS Cost Explorer. The cost is currently shown as '-'. The 'Cost (USD)' label is visible below the cost value.

Solution stack in Application Manager

Activate CloudWatch Application Insights

1. Sign in to the [Systems Manager console](#).

2. In the navigation pane, choose **Application Manager**.
3. In **Applications**, search for the application name for this solution and select it.

The application name will have **App Registry** in the **Application Source** column, and will have a combination of the solution name, Region, account ID, or stack name.

4. In the **Components** tree, choose the application stack you want to activate.
5. In the **Monitoring** tab, in **Application Insights**, select **Auto-configure Application Insights**.

The screenshot shows the AWS Application Insights interface. At the top, there is a navigation bar with tabs: Overview, Resources, Provisioning, Compliance, Monitoring (selected), OpsItems, Logs, Runbooks, and Cost. Below the navigation bar, the page title is "Application Insights (0) Info". There is a toggle for "View Ignored Problems" and an "Add an application" button. A search bar contains "Find problems". To the right of the search bar, there is a "Last 7 days" filter, a refresh button, and pagination controls showing "1" of 1 items. Below the search bar, there is a table header with columns: Problem su..., Status, Severity, Source, Start time, and Insights. The main content area displays a message: "Advanced monitoring is not enabled". Below this message, there is a paragraph explaining that a service-linked role (SLR) is created when an application is onboarded. At the bottom, there is a button labeled "Auto-configure Application Insights".

Monitoring for your applications is now activated and the following status box appears:

The screenshot shows the AWS Application Insights interface after successful activation. The navigation bar and top controls are the same as in the previous screenshot. The main content area now displays a green success message box: "Application monitoring has been successfully enabled. It will take some time to display any results. Please use the refresh button to view results." The rest of the interface, including the search bar and table header, remains the same.

Confirm cost tags associated with the solution

After you activate cost allocation tags associated with the solution, you must confirm the cost allocation tags to see the costs for this solution. To confirm cost allocation tags:

1. Sign in to the [Systems Manager console](#).
2. In the navigation pane, choose **Application Manager**.
3. In **Applications**, choose the application name for this solution and select it.

The application name will have **App Registry** in the **Application Source** column, and will have a combination of the solution name, Region, account ID, or stack name.

4. In the **Overview** tab, in **Cost**, select **Add user tag**.

5. On the **Add user tag** page, enter `confirm`, then select **Add user tag**.

The activation process can take up to 24 hours to complete and the tag data to appear.

Activate cost allocation tags associated with the solution

After you activate Cost Explorer, you must activate the cost allocation tags associated with this solution to see the costs for this solution. The cost allocation tags can only be activated from the management account for the organization. To activate cost allocation tags:

1. Sign in to the [AWS Billing and Cost Management and Cost Management console](#).
2. In the navigation pane, select **Cost Allocation Tags**.
3. On the **Cost allocation tags** page, filter for the AppManagerCFNStackKey tag, then select the tag from the results shown.
4. Choose **Activate**.

AWS Cost Explorer

You can see the overview of the costs associated with the application and application components within the Application Manager console through integration with AWS Cost Explorer, which must be first activated. Cost Explorer helps you manage costs by providing a view of your AWS resource costs and usage over time. To activate Cost Explorer for the solution:

1. Sign in to the [AWS Cost Management console](#).
2. In the navigation pane, select **Cost Explorer** to view the solution's costs and usage over time.

Update the solution

If you have previously deployed the solution, follow this procedure to update the solution's CloudFormation stack to get the latest version of the solution's framework.

1. Sign in to the [CloudFormation console](#), select your existing Scene Intelligence with Rosbag on AWS CloudFormation stack, and select **Update**.
2. Select **Replace current template**.
3. Under **Specify template**:
 - a. Select **Amazon S3 URL**.
 - b. Copy the link of the `scene-intelligence-with-rosbag-on-aws-create.template` [CloudFormation template](#).
 - c. Paste the link in the **Amazon S3 URL** box.
 - d. Verify that the correct template URL shows in the **Amazon S3 URL** text box, and choose **Next**. Choose **Next** again.
4. Under **Parameters**, review the parameters for the template and modify them as necessary. For details about the parameters, see [Launch the deployment stack](#).
5. Choose **Next**.
6. On the **Configure stack options** page, choose **Next**.
7. On the **Review** page, review and confirm the settings. Select the box acknowledging that the template will create IAM resources.
8. Choose **View change set** and verify the changes.
9. Choose **Update stack** to deploy the stack.

You can view the status of the stack in the AWS CloudFormation console in the **Status** column. You should receive a `UPDATE_COMPLETE` status in approximately 100–120 minutes.

Troubleshooting

This section provides known issue resolution when deploying the solution.

If these instructions don't address your issue, [Contact AWS Support](#) provides instructions for opening an AWS Support case for this solution.

Problem: Handling intermittent issues during solution deployment

You receive a **CREATE_FAILED** message for the single stack or the underlying module's CloudFormation stacks during the stack deployment.

Resolution

Complete the following steps to resolve this issue:

1. Sign in to the [CloudFormation console](#).
2. From the list of CloudFormation stacks, select any stack that is in **ROLLBACK_COMPLETE** state. This could be an underlying module's specific stack or the single-click scene-intelligence-with-rosbag-on-aws-create stack.
3. Delete the stack by following the instructions for [Deleting a stack on the AWS CloudFormation console](#) in the *AWS CloudFormation User Guide*.
4. Modify the scene-intelligence-with-rosbag-on-aws-create.template CloudFormation template by following these steps:
 - a. Download the [template](#).
 - b. Change the [wait condition](#) names. Wait condition names must be unique on every creation of a CloudFormation stack. The following is an example on how to modify the wait condition handler name from CodeBuildRunWaitConditionHandler01 to CodeBuildRunWaitConditionHandler02, and update the CallbackUrl to reflect the changed wait condition handler name under CodeBuildRun custom resource.

```
## Update WaitConditionHandle Logical Id  
  
CodeBuildRun:
```

```
Type: AWS::CloudFormation::CustomResource
Properties:
  ServiceToken: !GetAtt CodeBuildLambda.Arn
  BuildProjectName: ! Ref CreateUpdateCodeBuildProject
  CallbackUrl: !Ref CodeBuildRunWaitConditionHandler01 # Update Here
CodeBuildRunWaitConditionHandler01 # Update Here
  Type: AWS::CloudFormation::WaitConditionHandle

## Example of Updated Template Content

CodeBuildRun:
  Type: AWS::CloudFormation::CustomResource
  Properties:
    ServiceToken: !GetAtt CodeBuildLambda.Arn
    BuildProjectName: ! Ref CreateUpdateCodeBuildProject
    CallbackUrl: !Ref CodeBuildRunWaitConditionHandler02 # Update Here
CodeBuildRunWaitConditionHandler02 # Update Here
  Type: AWS::CloudFormation::WaitConditionHandle
```

5. Create a new deployment using the modified `scene-intelligence-with-rosvbag-on-aws-create.template` CloudFormation template by following the instructions in [Launch the stack](#).

Contact AWS Support

If you have [AWS Developer Support](#), [AWS Business Support](#), or [AWS Enterprise Support](#), you can use the Support Center to get expert assistance with this solution. The following sections provide instructions.

Create case

1. Sign in to [Support Center](#).
2. Choose **Create case**.

How can we help?

1. Choose **Technical**.
2. For **Service**, select **Solutions**.
3. For **Category**, select **Other Solutions**.
4. For **Severity**, select the option that best matches your use case.

5. When you enter the **Service**, **Category**, and **Severity**, the interface populates links to common troubleshooting questions. If you can't resolve your question with these links, choose **Next step: Additional information**.

Additional information

1. For **Subject**, enter text summarizing your question or issue.
2. For **Description**, describe the issue in detail.
3. Choose **Attach files**.
4. Attach the information that AWS Support needs to process the request.

Help us resolve your case faster

1. Enter the requested information.
2. Choose **Next step: Solve now or contact us**.

Solve now or contact us

1. Review the **Solve now** solutions.
2. If you can't resolve your issue with these solutions, choose **Contact us**, enter the requested information, and choose **Submit**.

Uninstall the solution

Follow the step-by-step instructions in this section to uninstall the solution into your account. You can use the AWS Management Console, AWS CLI, or [AWS CloudFormation](#).

Using the AWS Management Console

Complete the following steps to delete the `scene-intelligence-with-rosvbag-on-aws-create` and `scene-intelligence-with-rosvbag-on-aws-delete` stacks.

1. Sign in to the [CloudFormation console](#).
2. On the **Stacks** page, select this solution's stack.
3. Choose **Delete**.

Using AWS Command Line Interface

Determine whether the AWS Command Line Interface (AWS CLI) is available in your environment. For installation instructions, see [What Is the AWS Command Line Interface](#) in the *AWS CLI User Guide*. After confirming that the AWS CLI is available, run the following command.

```
$ aws cloudformation delete-stack --stack-name scene-intelligence-with-rosvbag-on-aws-  
create  
  
$ aws cloudformation wait stack-delete-complete --stack-name scene-intelligence-with-  
rosvbag-on-aws-create  
  
$ aws cloudformation delete-stack --stack-name scene-intelligence-with-rosvbag-on-aws-  
delete  
  
$ aws cloudformation wait stack-delete-complete --stack-name scene-intelligence-with-  
rosvbag-on-aws-delete
```

Using AWS CloudFormation

This solution uses a CloudFormation template to handle the uninstallation workflow.

Time to deploy: Approximately 100–120 minutes

AWS CloudFormation template for uninstallation

You can download the CloudFormation template for uninstalling this solution before deploying it.

[View template](#)

scene-intelligence-with-rosvbag-on-aws-delete.template - Use this template to destroy the modules related to the solution and all associated components orchestrated by an open source GitOps library called `seedfarmer`.

This CloudFormation template uninstalls the Scene Intelligence with Rosbag on AWS solution in the AWS Cloud.

Prerequisites for uninstallation

You must meet the following prerequisites before launching the uninstallation stack:

- Administrative permissions, or permissions sufficient to create and configure the AWS services used by these stacks.

Launch the uninstallation stack

Follow the step-by-step instructions in this section to uninstall the solution from your account.

Time to deploy: Approximately 100–120 minutes

1. Sign in to the [AWS Management Console](#) and select the button to launch the `scene-intelligence-with-rosvbag-on-aws-delete.template` AWS CloudFormation template.

[Launch solution](#)

2. The template launches in the US East (N. Virginia) Region by default. To launch the solution in a different AWS Region, use the Region selector in the console navigation bar.

Note

This solution uses the Amazon MWAA service, which is not currently available in all AWS Regions. You must launch this solution in a Region where Amazon MWAA is available. For the most current availability by Region, see the [AWS Regional Services List](#).

3. On the **Create stack** page, verify that the correct template URL is in the **Amazon S3 URL** text box and choose **Next**.
4. On the **Specify stack details** page, assign a name to your solution stack. For information about naming character limitations, see [IAM and AWS STS quotas](#) in the *AWS Identity and Access Management User Guide*.
5. Select **Next**.
6. On the **Configure stack options** page, choose **Next** after reviewing the settings.
7. On the **Review and create** page, review and confirm the settings. Select the box acknowledging that the template will create IAM resources.
8. Choose **Submit** to deploy the stack.

You can view the status of the stack in the AWS CloudFormation console in the **Status** column. You should receive a CREATE_COMPLETE status in approximately 100 - 120 minutes

After the stack reaches CREATE_COMPLETE status, the modules and the associated components related to Scene Intelligence with Rosbag on AWS solution will be destroyed. If the stack deployment fails, refer to [Troubleshooting](#).

You can then delete the CloudFormation stacks which deployed and destroyed the Scene Intelligence with Rosbag on AWS solution from the AWS Management Console or by using the AWS Command Line Interface.

Use the solution

This section provides a user guide for the solution.

Note

After the solution is deployed, you must [manually start the MWAA DAG](#) to process the files. After the DAG completes, all the rosbag data is available.

Verify the staged rosbag files

Complete the following steps to verify that the rosbag files are staged.

1. Sign in to the [Amazon S3 console](#).
2. Choose the bucket with a name similar to `addf-aws-solutions-raw-bucket-<hash>/rosbag-scene-detection/test-vehicle-01/072021/small11__2020-11-19-16-21-22_4.bag`.
3. There should be two `.bag` files in the bucket. These are the files we will pass to the DAG.

If the files aren't in the bucket, run the following CLI commands to stage the files. Replace *<hash>* with the unique numbering for the S3 bucket.

```
$ aws s3 cp s3://proserve-blocks-datasets-us-east-1/rosbag/test-vehicle-01/072021/small11__2020-11-19-16-21-22_4.bag \  
s3://addf-aws-solutions-raw-bucket-<hash>/rosbag-scene-detection/test-vehicle-01/072021/small11__2020-11-19-16-21-22_4.bag
```

```
$ aws s3 cp s3://proserve-blocks-datasets-us-east-1/rosbag/test-vehicle-01/072021/small12__2020-11-19-16-21-22_4.bag \  
s3://addf-aws-solutions-raw-bucket-<hash>/rosbag-scene-detection/test-vehicle-02/072021/small12__2020-11-19-16-21-22_4.bag
```

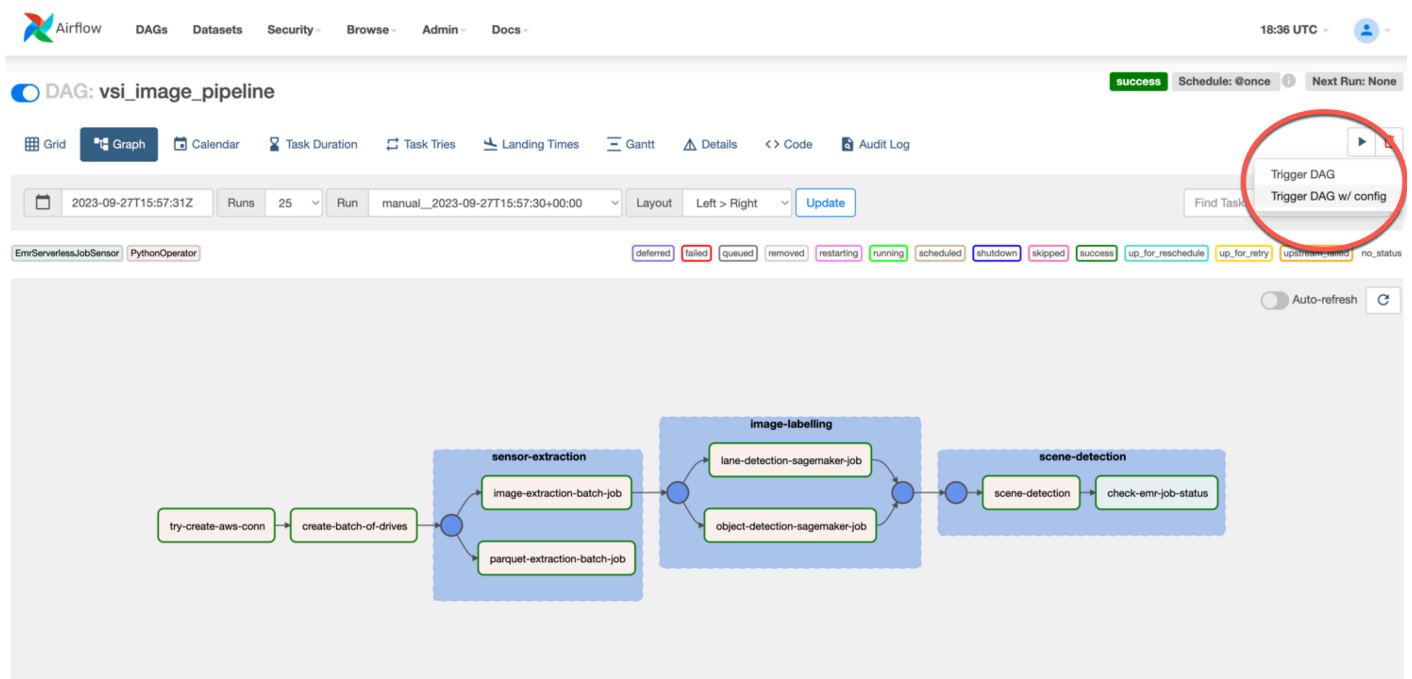

Invoke the DAG

Complete the following steps to invoke the DAG.

1. Sign in to the [Amazon MWA console](#).
2. Select **Environments** from the navigation menu.
3. Select `addf-aws-solutions-core-mwaa-environment` and choose **Open Airflow UI**. This opens a new window to the Airflow DAG.

4. Choose the `vsi-image-pipeline` DAG.
5. Choose **Play** and select **Trigger DAG w/ config**.

6. Provide the paths to the staged rosbag files. The following is an example, where you replace `<vehicle-name>` with the vehicle name, `<bucket>` with the S3 bucket name, and `<prefix-to-dag>` with your prefix:

```
{
  "drives_to_process": {
    "<vehicle-name>": {
      "bucket": "<bucket>",
```

```
    "prefix": "rosbag-scene-detection/test-vehicle-02/072021/ "
  },
  "<vehicle-name>": {
    "bucket": "<bucket>",
    "prefix": "<prefix-to-dag>"
  }
}
```

Note

The solution requires a minimum of two rosbag entries to invoke the DAG.

The following is an example with these fields completed, where the vehicle names are test-vehicle-01 and test-vehicle-02, the bucket name is addf-aws-solutions-raw-bucket-123456, and the prefix is rosbag-scene-detection/test-vehicle-01/072021/:

```
{
  "drives_to_process": {
    "test-vehicle-01": {
      "bucket": "addf-aws-solutions-raw-bucket-123456",
      "prefix": "rosbag-scene-detection/test-vehicle-01/072021/"
    },
    "test-vehicle-02": {
      "bucket": "addf-aws-solutions-raw-bucket-123456",
      "prefix": "rosbag-scene-detection/test-vehicle-02/072021/"
    }
  }
}
```

The following image shows the previous example code in the Airflow DAG window:

The screenshot shows the Airflow web interface for triggering a DAG named 'vsi_image_pipeline'. The interface includes the following elements:

- Logical date:** A date picker set to '2023-09-28T18:37:46+00'.
- Run id (Optional):** A text input field for 'Run ID'.
- Select Recent Configurations:** A dropdown menu currently showing 'Default parameters'.
- Configuration JSON (Optional, must be a dict object):** A code editor with the following JSON content:

```

1 {
2   "drives_to_process": {
3     "test-vehicle-01": {
4       "bucket": "addf-aws-solutions-raw-bucket-367e660c",
5       "prefix": "rosbag-scene-detection/test-vehicle-01/072021/"
6     },
7     "test-vehicle-02": {
8       "bucket": "addf-aws-solutions-raw-bucket-367e660c",
9       "prefix": "rosbag-scene-detection/test-vehicle-02/072021/"
10    }
11  }
12 }

```
- Help text:** 'To access configuration in your DAG use `{{ dag_run.conf }}`. As `core.dag_run_conf_overrides_params` is set to `False`, so passing any configuration here won't override task params.'
- Unpause DAG when triggered:** A radio button that is currently unselected.
- Buttons:** 'Trigger' and 'Cancel' buttons.

7. Choose **Trigger**. Wait for the DAG to complete running (approximately 20 minutes).

Inspect the DynamoDB table (optional)

After the DAG completes, the solution writes the application of the Spark code (business logic) to a DynamoDB table, and then forwards it OpenSearch Service.

Complete the following steps to inspect the DynamoDB table.

1. Sign in to the [Amazon DynamoDB console](#).
2. Choose **Tables** from the navigation menu.
3. Select the `addf-aws-solutions-core-metadata-storage-Rosbag-Scene-Metadata` table to see the output.

Access the OpenSearch Service dashboard

The solution sends the metadata to OpenSearch Service. The solution provides a proxy to access the OpenSearch Service dashboard. To access the proxy securely, the solution uses AWS Systems Manager and tunnel to the instance and leverage port-forwarding to the dashboard.

Note

To use this feature, you must have the [AWS Systems Manager CLI extension](#) installed.

Complete the following instructions to access the OpenSearch Service dashboard.

1. Obtain the proxy instance name, either by using the AWS Management Console or the AWS CLI.

Using the AWS Management Console:

- a. Sign in to the [Amazon EC2 console](#).
- b. Choose **Instances** from the navigation menu.
- c. Find and copy the instance name that starts with addf-aws-solutions.

Using the AWS CLI:

```
$ aws ec2 describe-instances \
  --filter "Name=tag:Name,Values=addf-aws-solutions-integration- opensearch-tunnel/
OSTunnel" \
```

```
--query "Reservations[].Instances[?State.Name == 'running'].InstanceId[]" \
--output text
```

2. Establish a tunnel by using the AWS CLI. This solution defaults the port to 3333.

The following is an example where you replace *<instance-name>* with the instance name:

```
$ aws ssm start-session --target <instance-name> \
--document-name AWS-StartPortForwardingSession \
--parameters '{"portNumber": ["3333"], "localPortNumber": ["3333"]}'
```

The following is an example where the instance name is i-123456789c45166cb:

```
$ aws ssm start-session --target i-123456789c45166cb \
--document-name AWS-StartPortForwardingSession \
--parameters '{"portNumber": ["3333"], "localPortNumber": ["3333"]}'
```

3. Use the following URL to open the dashboard: http://localhost:3333/_dashboards. This securely tunnels to the OpenSearch Service dashboard.

4. Add a new filter to discover your data. The partitions begin with rosbag, so we recommend selecting rosbag-* as a starting filter.

The screenshot shows the OpenSearch Dashboards interface. The search bar contains 'rosbag-*' and the results show 5 hits. The results are displayed in a table format with the following columns: scene_id, bag_file, start_time, end_time, topics_analyzed, bag_file_bucket, scene_length, _id, _type, and _score.

scene_id	bag_file	start_time	end_time	topics_analyzed	bag_file_bucket	scene_length	_id	_type	_score

Developer guide

This section provides the source code for the solution and additional customizations.

Source code

Visit our [GitHub repository](#) to download the source files for this solution and to share your customizations with others.

Customization guide

The DAG and Apache Spark code are located in the artifacts S3 bucket. The artifacts bucket has the naming pattern of `addf-aws-solutions-artifacts-bucket-<hash>`. The following is an example:

```
s3://addf-aws-solutions-artifacts-bucket-<hash>/dags/aws-solutions/analysis-rip/  
image_dags/*
```

In this location, the `detect_scenes.py` file houses the Apache Spark code that applies the business logic. You can access this file, modify it to suit your use case, upload it to same S3 bucket, and [re-run the DAG](#) in its entirety (rosgab extraction and object detection along with the Spark business logic).

Note

If you're only testing the Apache Spark changes, you can just [re-run the Amazon EMR Serverless job](#) in the application. A simple clone of a previously-run job runs your Apache Spark changes. Set the Apache Spark properties to include the `DynamoDB-Spark.jar` file. For instructions, see [Running jobs from the EMR Studio console](#).

Revisions

Date	Change
November 2023	Initial release.
November 2023	Documentation update: Added Confirm cost tags associated with the solution to the Monitoring the solution with AWS Service Catalog AppRegistry section.
February 2024	Release v1.0.1: Updated the Delete workflow to resolve intermittent failures when cleaning up the logs S3 bucket. Added instructions to update the solution . For more information, refer to the CHANGELOG.md file in the GitHub repository.
May 2024	Release v1.0.2: Updated the location for the rosbag files to a dedicated S3 bucket. For more information, refer to the CHANGELOG.md file in the GitHub repository.
