Success	13
Cleanup	13
Next steps	13
Setup	15
Setup overview	15
Set up authentication	16
Setup for single sign-on access for the SDK	16
Sign in using the AWS CLI	17
Install Java and a build tool	18
Additional authentication options	18
Set up an Apache Maven project	18
Prerequisites	18
Create a Maven project	19
Configure the Java compiler for Maven	19
Declare the SDK as a dependency	21
Set dependencies for SDK modules	21
Build your project	24
Set up a Gradle project	24
Set up a GraalVM Native Image project	31
Prerequisites	31
Create a project using the archetype	31
Build a native image	32
Use the SDK	34

Work with service clients	34
Create a service client	34
Default client configuration	35
Configure service clients	35
Close the service client	36
Make requests	36
Use requests to override client configuration	37
Handle responses	38
Handle exceptions	39
Use waiters	40
Set timeouts	40
Execution interceptors	41
Configure SDK authentication	42
Configure access to temporary credentials	42
Default credentials provider chain	44
Use a specific credentials provider	46
Use profiles	48
Load temporary credentials from an external process	51
Supply temporary credentials in code	56
Read IAM role credentials on Amazon EC2	59
Use AWS Regions	61
Explicitly configure an AWS Region	61
Determine Region from environment	62
Check for service availability	63
Choose a specific endpoint	63
Reduce SDK startup time for AWS Lambda	64
Use an AWS CRT-based HTTP client	64
Remove unused HTTP client dependencies	64
Configure service clients to shortcut lookups	65
Initialize the SDK client outside of the Lambda function handler	66
Minimize dependency injection	67
Use a Maven Archetype targeting AWS Lambda	67
Lambda SnapStart	67
Version 2.x changes that affect startup time	68
Additional resources	68
HTTP clients	68

Available clients	68
Client recommendations	69
Smart defaults	74
Configure the Apache-based HTTP client	75
Configure the URLConnection-based HTTP client	81
Configure the Netty-based HTTP client	87
Configure AWS CRT-based HTTP clients	93
Configure HTTP proxies	106

Developer Guide - AWS SDK for Java 2.x

The AWS SDK for Java provides a Java API for AWS services. Using the SDK, you can build Java applications that work with Amazon S3, Amazon EC2, DynamoDB, and more.

The AWS SDK for Java 2.x is a major rewrite of the version 1.x code base. It's built on top of Java 8+ and adds several frequently requested features. These include support for non-blocking I/O and the ability to plug in a different HTTP implementation at runtime.

We regularly add support for new services to the AWS SDK for Java. For a list of changes and features in a particular version, view the [change log](#).

Get started with the SDK

If you're ready to get hands-on with the SDK, follow the [Get started tutorial](#) tutorial.

To set up your development environment, see [Setup](#).

If you're currently using version 1.x of the SDK for Java, see [Migrate to version 2](#) for specific guidance.

For information on making requests to Amazon S3, DynamoDB, Amazon EC2 and other AWS services, see [Use the SDK for Java](#) and [Work with AWS services](#).

Develop mobile applications

If you're a mobile app developer, Amazon Web Services provides the [AWS Amplify](#) framework.

Maintenance and support for SDK major versions

For information about maintenance and support for SDK major versions and their underlying dependencies, see the following topics in the [AWS SDKs and Tools Reference Guide](#):

- [AWS SDKs and Tools Maintenance Policy](#)
- [AWS SDKs and Tools Version Support Matrix](#)

Additional resources

In addition to this guide, the following are valuable online resources for AWS SDK for Java developers:

- [AWS SDK for Java 2.x API Reference](#)
- [Java developer blog](#)
- [Java development topic in AWS re:Post](#)
- [SDK source](#) on GitHub
- [AWS SDK Code Examples library](#)
- [@awsforjava](#) (Twitter)

Contribute to the SDK

Developers can also contribute feedback through the following channels:

- Submit issues on GitHub:
 - [Submit Developer Guide documentation issues](#)
 - [Submit SDK issues](#)
- Join an informal chat about the SDK on the AWS SDK for Java 2.x [gitter channel](#)

Get started with the AWS SDK for Java 2.x

The AWS SDK for Java 2.x provides Java APIs for Amazon Web Services (AWS). Using the SDK, you can build Java applications that work with Amazon S3, Amazon EC2, DynamoDB, and more.

This tutorial shows you how to use [Apache Maven](#) to define dependencies for the SDK for Java 2.x and then write code that connects to Amazon S3 to upload a file.

Follow these steps to complete this tutorial:

- [Step 1: Set up for this tutorial](#)
- [Step 2: Create the project](#)
- [Step 3: Write the code](#)
- [Step 4: Build and run the application](#)

Step 1: Set up for this tutorial

Before you begin this tutorial, you need the following:

- Permission to access Amazon S3
- A Java development environment that is configured to access AWS services using single sign-on to the AWS IAM Identity Center

Use the instructions in [???](#) to get set up for this tutorial. After you have [configured your development environment with single sign-on access](#) for the Java SDK and you have an [active AWS access portal session](#), continue with Step 2 of this tutorial.

Step 2: Create the project

To create the project for this tutorial, you run a Maven command that prompts you for input on how to configure the project. After all input is entered and confirmed, Maven finishes building out the project by creating a `pom.xml` and creates stub Java files.

1. Open a terminal or command prompt window and navigate to a directory of your choice, for example, your Desktop or Home folder.

2. Enter the following command at the terminal and press Enter.

```
mvn archetype:generate \
  -DarchetypeGroupId=software.amazon.awssdk \
  -DarchetypeArtifactId=archetype-app-quickstart \
  -DarchetypeVersion=2.27.21
```

3. Enter the value listed in the second column for each prompt.

Prompt	Value to enter
Define value for property 'service':	s3
Define value for property 'httpClient' :	apache-client
Define value for property 'nativeImage' :	false
Define value for property 'credentialProvider'	identity-center
Define value for property 'groupId':	org.example
Define value for property 'artifactId':	getstarted
Define value for property 'version' 1.0-SNAPSHOT:	<Enter>
Define value for property 'package' org.example:	<Enter>

4. After the last value is entered, Maven lists the choices you made. Confirm by entering *Y* or re-enter values by entering *N*.

Maven creates the project folder named `getstarted` based on the `artifactId` value that you entered. Inside the `getstarted` folder, find a `README.md` file that you can review, a `pom.xml` file, and a `src` directory.

Maven builds the following directory tree.

```
getstarted
### README.md
### pom.xml
### src
### main
#   ### java
#   #   ### org
#   #       ### example
#   #           ### App.java
#   #           ### DependencyFactory.java
#   #           ### Handler.java
#   ### resources
#       ### simplelogger.properties
### test
### java
### org
### example
### HandlerTest.java

10 directories, 7 files
```

The following shows the contents of the `pom.xml` project file.

pom.xml

The `dependencyManagement` section contains a dependency to the AWS SDK for Java 2.x and the `dependencies` section has a dependency for Amazon S3. The project uses Java 1.8 because of the 1.8 value in the `maven.compiler.source` and `maven.compiler.target` properties.

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://
maven.apache.org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>org.example</groupId>
```

```

<build>
  <plugins>
    <plugin>
      <groupId>org.apache.maven.plugins</groupId>
      <artifactId>maven-compiler-plugin</artifactId>
      <version>${maven.compiler.plugin.version}</version>
    </plugin>
  </plugins>
</build>

</project>
```

Step 3: Write the code

The following code shows the `App` class created by Maven. The `main` method is the entry point into the application, which creates an instance of the `Handler` class and then calls its `sendRequest` method.

App class

```
package org.example;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class App {
    private static final Logger logger = LoggerFactory.getLogger(App.class);

    public static void main(String... args) {
        logger.info("Application starts");

        Handler handler = new Handler();
        handler.sendRequest();
    }
}
```

```
        logger.info("Application ends");
    }
}
```

The `DependencyFactory` class created by Maven contains the `s3Client` factory method that builds and returns an [S3Client](#) instance. The `S3Client` instance uses an instance of the Apache-based HTTP client. This is because you specified `apache-client` when Maven prompted you for which HTTP client to use.

The `DependencyFactory` is shown in the following code.

DependencyFactory class

```
package org.example;

import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;

/**
 * The module containing all dependencies required by the {@link Handler}.
 */
public class DependencyFactory {

    private DependencyFactory() {}

    /**
     * @return an instance of S3Client
     */
    public static S3Client s3Client() {
        return S3Client.builder()
            .httpClientBuilder(ApacheHttpClient.builder())
            .build();
    }
}
```

The `Handler` class contains the main logic of your program. When an instance of `Handler` is created in the `App` class, the `DependencyFactory` furnishes the `S3Client` service client. Your code uses the `S3Client` instance to call the Amazon S3 service.

Maven generates the following `Handler` class with a `TODO` comment. The next step in the tutorial replaces the `TODO` with code.

Handler class, Maven-generated

```
package org.example;

import software.amazon.awssdk.services.s3.S3Client;

public class Handler {
    private final S3Client s3Client;

    public Handler() {
        s3Client = DependencyFactory.s3Client();
    }

    public void sendRequest() {
        // TODO: invoking the api calls using s3Client.
    }
}
```

To fill in the logic, replace the entire contents of the `Handler` class with the following code. The `sendRequest` method is filled in and the necessary imports are added.

Handler class, implemented

The code first creates a new `S3` bucket with the last part of the name generated using `System.currentTimeMillis()` in order to make the bucket name unique.

After creating the bucket in the `createBucket()` method, the program uploads an object using the [putObject](#) method of `S3Client`. The contents of the object is a simple string created with the `RequestBody.fromString` method.

Finally, the program deletes the object followed by the bucket in the `cleanup` method.

```
package org.example;

import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
```

```
import software.amazon.awssdk.services.s3.model.S3Exception;

public class Handler {
    private final S3Client s3Client;

    public Handler() {
        s3Client = DependencyFactory.s3Client();
    }

    public void sendRequest() {
        String bucket = "bucket" + System.currentTimeMillis();
        String key = "key";

        createBucket(s3Client, bucket);

        System.out.println("Uploading object...");

        s3Client.putObject(PutObjectRequest.builder().bucket(bucket).key(key)
            .build(),
            RequestBody.fromString("Testing with the {sdk-java}"));

        System.out.println("Upload complete");
        System.out.printf("%n");

        cleanUp(s3Client, bucket, key);

        System.out.println("Closing the connection to {S3}");
        s3Client.close();
        System.out.println("Connection closed");
        System.out.println("Exiting...");
    }

    public static void createBucket(S3Client s3Client, String bucketName) {
        try {
            s3Client.createBucket(CreateBucketRequest
                .builder()
                .bucket(bucketName)
                .build());
            System.out.println("Creating bucket: " + bucketName);
            s3Client.waiter().waitUntilBucketExists(HeadBucketRequest.builder()
                .bucket(bucketName)
                .build());
            System.out.println(bucketName + " is ready.");
        }
    }
}
```

```
        System.out.printf("%n");
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

public static void cleanUp(S3Client s3Client, String bucketName, String keyName) {
    System.out.println("Cleaning up...");
    try {
        System.out.println("Deleting object: " + keyName);
        DeleteObjectRequest deleteObjectRequest =
DeleteObjectRequest.builder().bucket(bucketName).key(keyName).build();
        s3Client.deleteObject(deleteObjectRequest);
        System.out.println(keyName + " has been deleted.");
        System.out.println("Deleting bucket: " + bucketName);
        DeleteBucketRequest deleteBucketRequest =
DeleteBucketRequest.builder().bucket(bucketName).build();
        s3Client.deleteBucket(deleteBucketRequest);
        System.out.println(bucketName + " has been deleted.");
        System.out.printf("%n");
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    System.out.println("Cleanup complete");
    System.out.printf("%n");
}
}
```

Step 4: Build and run the application

After the project is created and contains the complete `Handler` class, build and run the application.

1. Make sure that you have an active IAM Identity Center session. To do so, run the AWS Command Line Interface command `aws sts get-caller-identity` and check the response. If you don't have an active session, see [this section](#) for instructions.
2. Open a terminal or command prompt window and navigate to your project directory `getstarted`.
3. Use the following command to build your project:

```
mvn clean package
```

4. Use the following command to run the application.

```
mvn exec:java -Dexec.mainClass="org.example.App"
```

To view the new bucket and object that the program creates, perform the following steps.

1. In `Handler.java`, comment out the line `cleanup(s3Client, bucket, key)` in the `sendRequest` method and save the file.
2. Rebuild the project by running `mvn clean package`.
3. Rerun `mvn exec:java -Dexec.mainClass="org.example.App"` to upload the text object once more.
4. Sign in to [the S3 console](#) to view the new object in the newly created bucket.

After you view the file, delete the object, and then delete the bucket.

Success

If your Maven project built and ran without error, then congratulations! You have successfully built your first Java application using the SDK for Java 2.x.

Cleanup

To clean up the resources you created during this tutorial, do the following:

- If you haven't done so already, in [the S3 console](#), delete any objects and any buckets created when you ran the application.
- Delete the project folder (`getstarted`).

Next steps

Now that you have the basics down, you can learn about the following:

- [Working with Amazon S3](#)

- [Working with other Amazon Web Services](#), such as [DynamoDB](#), [Amazon EC2](#), and [various database services](#)
- [Use the SDK](#)
- [Security for the AWS SDK for Java](#)

Set up the AWS SDK for Java 2.x

This section provides information about how to set up your development environment and projects to use the AWS SDK for Java 2.x.

Setup overview

To successfully develop applications that access AWS services using the AWS SDK for Java, the following conditions are required:

- The Java SDK must have access to credentials to [authenticate requests](#) on your behalf.
- The [permissions of the IAM role](#) configured for the SDK must allow access to the AWS services that your application requires. The permissions associated with the **PowerUserAccess** AWS managed policy are sufficient for most development needs.
- A development environment with the following elements:
 - [Shared configuration files](#) that are set up in at least one of the following ways:
 - The config file contains [IAM Identity Center single sign-on settings](#) so that the SDK can get AWS credentials.
 - The `credentials` file contains temporary credentials.
 - An [installation of Java 8](#) or later.
 - A [build automation tool](#) such as [Maven](#) or [Gradle](#).
 - A text editor to work with code.
 - (Optional, but recommended) An IDE (integrated development environment) such as [IntelliJ IDEA](#), [Eclipse](#), or [NetBeans](#).

When you use an IDE, you can also integrate AWS Toolkits to more easily work with AWS services. The [AWS Toolkit for IntelliJ](#) and [AWS Toolkit for Eclipse](#) are two toolkits that you can use for Java development.

- An active AWS access portal session when you are ready to run your application. You use the AWS Command Line Interface to [initiate the sign-in process](#) to IAM Identity Center's AWS access portal.

⚠ Important

The instructions in this setup section assume that you or organization uses IAM Identity Center. If your organization uses an external identity provider that works independently of IAM Identity Center, find out how you can get temporary credentials for the SDK for Java to use. Follow [these instructions](#) to add temporary credentials to the `~/.aws/credentials` file.

If your identity provider adds temporary credentials automatically to the `~/.aws/credentials` file, make sure that the profile name is `[default]` so that you do not need to provide a profile name to the SDK or AWS CLI.

Set up authentication

The [Authentication and access](#) topic in the AWS SDKs and Tools Reference Guide describes the different options to authenticate. We recommend that you follow the instructions to [set up access to the IAM Identity Center](#) so the SDK can acquire credentials. After following the instructions, [your system is set up](#) to allow the SDK to authenticate requests.

Setup for single sign-on access for the SDK

After you complete Step 2 in the [programmatic access section](#) so that the SDK can use IAM Identity Center authentication, your system should contain the following elements.

- The AWS CLI, which you use to start an [AWS access portal session](#) before you run your application.
- An `~/.aws/config` file that contains a [default profile](#). The SDK for Java uses the profile's SSO token provider configuration to acquire credentials before sending requests to AWS. The `sso_role_name` value, which is an IAM role connected to an IAM Identity Center permission set, should allow access to the AWS services used in your application.

The following sample `config` file shows a default profile set up with SSO token provider configuration. The profile's `sso_session` setting refers to the named `sso-session` section. The `sso-session` section contains settings to initiate an AWS access portal session.

```
[default]
sso_session = my-ss0
```

```
sso_account_id = 111122223333
sso_role_name = SampleRole
region = us-east-1
output = json

[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://provided-domain.awsapps.com/start
sso_registration_scopes = sso:account:access
```

For more details about the settings used in the SSO token provider configuration, see [SSO token provider configuration](#) in the AWS SDKs and Tools Reference Guide.

If your development environment is not set up for programmatic access as previously shown, follow [Step 2 in the SDKs Reference Guide](#).

Sign in using the AWS CLI

Before running an application that accesses AWS services, you need an active AWS access portal session in order for the SDK to use IAM Identity Center authentication to resolve credentials. Run the following command in the AWS CLI to sign in to the AWS access portal.

```
aws sso login
```

Since you have a default profile setup, you do not need to call the command with a `--profile` option. If your SSO token provider configuration is using a named profile, the command is `aws sso login --profile named-profile`.

To test if you already have an active session, run the following AWS CLI command.

```
aws sts get-caller-identity
```

The response to this command should report the IAM Identity Center account and permission set configured in the shared config file.

Note

If you already have an active AWS access portal session and run `aws sso login`, you will not be required to provide credentials.

However, you will see a dialog that requests permission for `botocore` to access your information. `botocore` is the foundation for the AWS CLI .
Select **Allow** to authorize access to your information for the AWS CLI and SDK for Java.

Install Java and a build tool

Your development environment needs the following:

- Java 8 or later. The AWS SDK for Java works with the [Oracle Java SE Development Kit](#) and with distributions of Open Java Development Kit (OpenJDK) such as [Amazon Corretto](#), [Red Hat OpenJDK](#), and [Adoptium](#).
- A build tool or IDE that supports Maven Central such as Apache Maven, Gradle, or IntelliJ.
 - For information about how to install and use Maven, see <https://maven.apache.org/>.
 - For information about how to install and use Gradle, see <https://gradle.org/>.
 - For information about how to install and use IntelliJ IDEA, see <https://www.jetbrains.com/idea/>.

Additional authentication options

For more options on authentication for the SDK, such as the use of profiles and environment variables, see the [configuration](#) chapter in the AWS SDKs and Tools Reference Guide.

Set up an Apache Maven project

You can use [Apache Maven](#) to set up and build AWS SDK for Java projects, or to [build the SDK itself](#).

Prerequisites

To use the AWS SDK for Java with Maven, you need the following:

- Java 8.0 or later. You can download the latest Java SE Development Kit software from <http://www.oracle.com/technetwork/java/javase/downloads/>. The AWS SDK for Java also works with [OpenJDK](#) and Amazon Corretto, a distribution of the Open Java Development Kit (OpenJDK). Download the latest OpenJDK version from <https://openjdk.java.net/install/index.html>. Download the latest Amazon Corretto 8 or Amazon Corretto 11 version from [the Corretto page](#).

- *Apache Maven*. If you need to install Maven, go to <http://maven.apache.org/> to download and install it.

Create a Maven project

To create a Maven project from the command line, run the following command from a terminal or command prompt window.

```
mvn -B archetype:generate \  
-DarchetypeGroupId=software.amazon.awssdk \  
-DarchetypeArtifactId=archetype-lambda -Dservice=s3 -Dregion=US_WEST_2 \  
-DarchetypeVersion=2.X.X \  
-DgroupId=com.example.myapp \  
-DartifactId=myapp
```

Note

Replace *com.example.myapp* with the full package namespace of your application. Also replace *myapp* with your project name. This becomes the name of the directory for your project.

To use the latest version of the archetype, replace *2.X.X* with the [latest from Maven central](#).

This command creates a Maven project using the archetype templating toolkit. The archetype generates the scaffolding for an AWS Lambda function handler project. This project archetype is preconfigured to compile with Java SE 8 and includes a dependency to the version of the SDK for Java 2.x specified with `-DarchetypeVersion`.

For more information about creating and configuring Maven projects, see the [Maven Getting Started Guide](#).

Configure the Java compiler for Maven

If you created your project using the AWS Lambda project archetype as described previously, the configuration of the Java compiler is already done for you.

To verify that this configuration is present, start by opening the `pom.xml` file from the project folder you created (for example, `myapp`) when you executed the previous command. Look on

lines 11 and 12 to see the Java compiler version setting for this Maven project, and the required inclusion of the Maven compiler plugin on lines 71-75.

```
<project>
  <properties>
    <maven.compiler.source>1.8</maven.compiler.source>
    <maven.compiler.target>1.8</maven.compiler.target>
  </properties>
  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-compiler-plugin</artifactId>
        <version>${maven.compiler.plugin.version}</version>
      </plugin>
    </plugins>
  </build>
</project>
```

If you create your project with a different archetype or by using another method, you must ensure that the Maven compiler plugin is part of the build and that its source and target properties are both set to **1.8** in the `pom.xml` file.

See the previous snippet for one way to configure these required settings.

Alternatively, you can configure the compiler configuration inline with the plugin declaration, as follows.

```
<project>
  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-compiler-plugin</artifactId>
        <configuration>
          <source>1.8</source>
          <target>1.8</target>
        </configuration>
      </plugin>
    </plugins>
  </build>
</project>
```

Declare the SDK as a dependency

To use the AWS SDK for Java in your project, you need to declare it as a dependency in your project's `pom.xml` file.

If you created your project using the project archetype as described previously, the latest version of the SDK is already configured as a dependency in your project.

The archetype generates a BOM (bill of materials) artifact dependency for the `software.amazon.awssdk` group id. With a BOM, you do not have to specify the maven version for individual artifact dependencies that share the same group id.

If you created your Maven project in a different way, configure the latest version of the SDK for your project by ensuring that the `pom.xml` file contains the following.

```
<project>
  <properties>
    <aws.java.sdk.version>2.X.X</aws.java.sdk.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.java.sdk.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
</project>
```

Note

Replace `2.X.X` in the `pom.xml` file with the [latest version of the AWS SDK for Java 2.x](#).

Set dependencies for SDK modules

Now that you have configured the SDK, you can add dependencies for one or more of the AWS SDK for Java modules to use in your project.

Although you can specify the version number for each component, you don't need to because you already declared the SDK version in the `dependencyManagement` section using the bill of materials artifact. To load a different version of a given module, specify a version number for its dependency.

If you created your project using the project archetype as described previously, your project is already configured with multiple dependencies. These include dependences for AWS Lambda function handlers and Amazon S3, as follows.

```
<project>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>s3</artifactId>
      <exclusions>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>netty-nio-client</artifactId>
        </exclusion>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>apache-client</artifactId>
        </exclusion>
      </exclusions>
    </dependency>

    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>url-connection-client</artifactId>
    </dependency>

    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-lambda-java-core</artifactId>
      <version>${aws.lambda.java.version}</version>
    </dependency>
  </dependencies>
</project>
```

Note

In the `pom.xml` example above, the dependencies are from different `groupId`s. The `s3` dependency is from `software.amazon.awssdk`, whereas the `aws-lambda-java-core` dependency is from `com.amazonaws`. The BOM dependency management configuration affects artifacts for `software.amazon.awssdk`, so a version is needed for the `aws-lambda-java-core` artifact.

For the development of *Lambda function handlers* using the SDK for Java 2.x, `aws-lambda-java-core` is the correct dependency. However, if your application needs to manage Lambda resources, using operations such as `listFunctions`, `deleteFunction`, `invokeFunction`, and `createFunction`, your application requires the following dependency.

```
<groupId>software.amazon.awssdk</groupId>
<artifactId>lambda</artifactId>
```

Note

The `s3` dependency excludes the `netty-nio-client` and `apache-client` transitive dependencies. In place of either of those HTTP clients, the archetype includes the `url-connection-client` dependency, which helps [reduce the startup latency for AWS Lambda functions](#).

Add the modules to your project for the AWS service and features you need for your project. The modules (dependencies) that are managed by the AWS SDK for Java BOM are listed on the [Maven central repository](#).

Note

You can look at the `pom.xml` file from a code example to determine which dependencies you need for your project. For example, if you're interested in the dependencies for the DynamoDB service, see [this example](#) from the [AWS Code Examples Repository](#) on GitHub. (Look for the `pom.xml` file under [/javav2/example_code/dynamodb](#).)

Build the entire SDK into your project

To optimize your application, we strongly recommend that you pull in only the components you need instead of the entire SDK. However, to build the entire AWS SDK for Java into your project, declare it in your `pom.xml` file, as follows.

```
<project>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-sdk-java</artifactId>
      <version>2.X.X</version>
    </dependency>
  </dependencies>
</project>
```

Build your project

After you configure the `pom.xml` file, you can use Maven to build your project.

To build your Maven project from the command line, open a terminal or command prompt window, navigate to your project directory (for example, `myapp`), enter or paste the following command, then press Enter or Return.

```
mvn package
```

This creates a single `.jar` file (JAR) in the `target` directory (for example, `myapp/target`). This JAR contains all of the SDK modules you specified as dependencies in your `pom.xml` file.

Set up a Gradle project

You can use [Gradle](#) to set up and build AWS SDK for Java projects.

The initial steps in the following example come from [Gradle's Getting Started guide](#) for version 8.4. If you use a different version, your results may differ slightly.

To create a Java application with Gradle (command line)

1. Create a directory to hold your project. In this example, `demo` is the directory name.

2. Inside the demo directory, execute the `gradle init` command and supply the values highlighted in red as shown in the following command line output. For the walk through, we choose Kotlin as the build script DSL language, but a complete example for Groovy is also shown at the end of this topic.

```
> gradle init
Starting a Gradle Daemon (subsequent builds will be faster)

Select type of project to generate:
1: basic
2: application
3: library
4: Gradle plugin
Enter selection (default: basic) [1..4] 2

Select implementation language:
1: C++
2: Groovy
3: Java
4: Kotlin
5: Scala
6: Swift
Enter selection (default: Java) [1..6] 3

Generate multiple subprojects for application? (default: no) [yes, no] no
Select build script DSL:
1: Kotlin
2: Groovy
Enter selection (default: Kotlin) [1..2] <Enter>

Select test framework:
1: JUnit 4
2: TestNG
3: Spock
4: JUnit Jupiter
Enter selection (default: JUnit Jupiter) [1..4] 4

Project name (default: demo): <Enter>
Source package (default: demo): <Enter>
Enter target version of Java (min. 7) (default: 11): <Enter>
Generate build using new APIs and behavior (some features may change in the next
minor release)? (default: no) [yes, no] <Enter>
```

```
> Task :init
To learn more about Gradle by exploring our Samples at https://docs.gradle.org/8.4/samples/sample\_building\_java\_applications.html

BUILD SUCCESSFUL in 3m 43s
2 actionable tasks: 2 executed
```

3. After the `init` task completes, the `demo` directory contains the following tree structure. We take a closer look at the main build file, `build.gradle.kts` (highlighted in red), in the next section.

```
### app
#   ### build.gradle.kts
#   ### src
#       ### main
#           #   ### java
#               #   #   ### demo
#                   #   #   ### App.java
#                       #   ### resources
#                   ### test
#                       ### java
#                           #   ### demo
#                               #   ### AppTest.java
#                                   ### resources
### gradle
#   ### wrapper
#       ### gradle-wrapper.jar
#       ### gradle-wrapper.properties
### gradlew
### gradlew.bat
### settings.gradle.kts
```

The `build.gradle.kts` file contains the following scaffolded content.

```
/*
 * This file was generated by the Gradle 'init' task.
 *
 * This generated file contains a sample Java application project to get you
 * started.
 * For more details on building Java & JVM projects, please refer to https://docs.gradle.org/8.4/userguide/building\_java\_projects.html in the Gradle
 * documentation.
```

```
*/

plugins {
    // Apply the application plugin to add support for building a CLI application
    in Java.
    application
}

repositories {
    // Use Maven Central for resolving dependencies.
    mavenCentral()
}

dependencies {
    // Use JUnit Jupiter for testing.
    testImplementation("org.junit.jupiter:junit-jupiter:5.9.3")

    testRuntimeOnly("org.junit.platform:junit-platform-launcher")

    // This dependency is used by the application.
    implementation("com.google.guava:guava:33.3.0-jre")
}

// Apply a specific Java toolchain to ease working on different environments.
java {
    toolchain {
        languageVersion.set(JavaLanguageVersion.of(11))
    }
}

application {
    // Define the main class for the application.
    mainClass.set("demo.App")
}

tasks.named<Test>("test") {
    // Use JUnit Platform for unit tests.
    useJUnitPlatform()
}
```

4. Use the scaffolded Gradle build file as the basis for your AWS project.

- a. To manage SDK dependencies for your Gradle project, add the Maven bill of materials (BOM) for the AWS SDK for Java 2.x to the dependencies section of the `build.gradle.kts` file.

```
...
dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.27.21"))
    // With the bom declared, you specify individual SDK dependencies without a
    // version.
    ...
}
...
```

 **Note**

In this example build file, replace `2.27.21` with the latest version of the SDK for Java 2.x. Find the latest version available in [Maven central repository](#).

- b. Specify the SDK modules your application needs in the dependencies section. As an example, the following adds a dependency on Amazon Simple Storage Service.

```
...
dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.27.21"))
    implementation("software.amazon.awssdk:s3")
    ...
}
...
```

Gradle automatically resolves the correct version of declared dependencies by using the information from the BOM.

The following examples show complete Gradle build files in both the Kotlin and Groovy DSLs. The build file contains dependencies for Amazon S3, authentication, logging, and testing. The source and target version of Java is version 11.

Kotlin DSL (build.gradle.kts)

```
/*
 * This file was generated by the Gradle 'init' task.
 *
 * This generated file contains a sample Java application project to get you
 * started.
 * For more details on building Java & JVM projects, please refer to https://docs.gradle.org/8.4/userguide/building\_java\_projects.html in the Gradle
 * documentation.
 */

plugins {
    // Apply the application plugin to add support for building a CLI application in
    // Java.
    application
}

repositories {
    // Use Maven Central for resolving dependencies.
    mavenCentral()
}

dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.20.56"))
    implementation("software.amazon.awssdk:s3")

Set up a GraalVM Native Image project for the AWS SDK for Java

With versions 2.16.1 and later, the AWS SDK for Java provides out-of-the-box support for GraalVM Native Image applications. Use the archetype-app-quickstart Maven archetype to set up a project with built-in native image support.

Prerequisites

- Complete the steps in [Setting up the AWS SDK for Java 2.x](#).
- Install [GraalVM Native Image](#).

Create a project using the archetype

To create a Maven project with built-in native image support, in a terminal or command prompt window, use the following command.

Note

Replace `com.example.mynativeimageapp` with the full package namespace of your application. Also replace `mynativeimageapp` with your project name. This becomes the name of the directory for your project.

```
mvn archetype:generate \  
  -DarchetypeGroupId=software.amazon.awssdk \  
  -DarchetypeArtifactId=archetype-app-quickstart \  
  -DarchetypeVersion=2.27.21\  
  -DnativeImage=true \  
  -DhttpClient=apache-client \  
  -Dservice=s3 \  
  -DgroupId=com.example.mynativeimageapp \  
  -DartifactId=mynativeimageapp \  
  -DinteractiveMode=false
```

This command creates a Maven project configured with dependencies for the AWS SDK for Java, Amazon S3, and the `ApacheHttpClient` HTTP client. It also includes a dependency for the [GraalVM Native Image Maven plugin](#), so that you can build native images using Maven.

To include dependencies for a different Amazon Web Services, set the value of the `-Dservice` parameter to the artifact ID of that service. Examples include `dynamodb`, `comprehend`, and `pinpoint`. For a complete list of artifact IDs, see the list of managed dependencies for [software.amazon.awssdk on Maven Central](#).

To use an asynchronous HTTP client, set the `-DhttpClient` parameter to `netty-nio-client`. To use `URLConnectionHttpClient` as the synchronous HTTP client instead of `apache-client`, set the `-DhttpClient` parameter to `url-connection-client`.

Build a native image

After you create the project, run the following command from your project directory, for example, `mynativeimageapp`:

```
mvn package -P native-image
```

This creates a native image application in the target directory, for example, `target/mynativeimageapp`.

Use the AWS SDK for Java 2.x

After completing the steps in [Setting up the SDK](#), you are ready to make requests to AWS services such as Amazon S3, DynamoDB, IAM, Amazon EC2, and more.

Work with service clients

Create a service client

To make a request to an AWS service, you must first instantiate a service client for that service by using the static factory method, `builder()`. The `builder()` method returns a `builder` object that allows you to customize the service client. The fluent setter methods return the `builder` object, so that you can chain the method calls for convenience and for more readable code. After you configure the properties you want, call the `build()` method to create the client.

As an example, the following code snippet instantiates an `Ec2Client` object as a service client for Amazon EC2.

```
Region region = Region.US_WEST_2;
Ec2Client ec2Client = Ec2Client.builder()
    .region(region)
    .build();
```

Note

Service clients in the SDK are thread-safe. For best performance, treat them as long-lived objects. Each client has its own connection pool resource that is released when the client is garbage collected.

A service client object is immutable, so you must create a new client for each service to which you make requests, or if you want to use a different configuration for making requests to the same service.

Specifying the `Region` in the service client builder is not required for all AWS services; however, it is a best practice to set the `Region` for the API calls you make in your applications. See [AWS region selection](#) for more information.

Default client configuration

The client builders have another factory method named `create()`. This method creates a service client with the default configuration. It uses the default provider chain to load credentials and the AWS Region. If credentials or the Region can't be determined from the environment that the application is running in, the call to `create` fails. See [Using credentials](#) and [Region selection](#) for more information about how the SDK determines the credentials and Region to use.

For example, the following code snippet instantiates a `DynamoDbClient` object as a service client for Amazon DynamoDB:

```
DynamoDbClient dynamoDbClient = DynamoDbClient.create();
```

Configure service clients

To customize the configuration of a service client, use the setters on the `builder()` factory method. For convenience and to create more readable code, chain the methods to set multiple configuration options.

The following example shows an `S3Client` that is configured with several custom settings.

```
ClientOverrideConfiguration clientOverrideConfiguration =
    ClientOverrideConfiguration.builder()
        .apiCallAttemptTimeout(Duration.ofSeconds(1))
        .retryPolicy(RetryPolicy.builder().numRetries(10).build())
        .addMetricPublisher(CloudWatchMetricPublisher.create())
        .build();

Region region = Region.US_WEST_2;
S3Client s3Client = S3Client.builder()
    .region(region)

    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .overrideConfiguration(clientOverrideConfiguration)
    .httpClientBuilder(ApacheHttpClient.builder())

    .proxyConfiguration(proxyConfig.build(ProxyConfiguration.builder()))
    .build();
```

Close the service client

As a best practice, you should use a service clients for multiple API service calls during the life of an application. However, if you need a service client for a one-time use or no longer need the service client, close it.

Call the `close()` method when the service client is no longer needed to free up resources.

```
ec2Client.close();
```

If you need a service client for one-time use, you can instantiate the service client as a resource in a `try-with-resources` statement. Service clients implement the [Autoclosable](#) interface, so the JDK automatically calls the `close()` method at the end of the statement.

The following example demonstrates how to use a service client for a one-off call. The `StsClient` that calls the AWS Security Token Service is closed after it returns the account ID.

```
import software.amazon.awssdk.services.sts.StsClient;

String getAccountID() {
    try (StsClient stsClient = StsClient.create()) {
        return stsClient.getCallerIdentity().account();
    }
}
```

Make requests

Use the service client to make requests to the corresponding AWS service.

For example, this code snippet shows how to create a `RunInstancesRequest` object to create a new Amazon EC2 instance:

```
// Create the request by using the fluid setter methods of the request builder.
RunInstancesRequest runInstancesRequest = RunInstancesRequest.builder()
    .imageId(amiId)
    .instanceType(InstanceType.T1_MICRO)
    .maxCount(1)
    .minCount(1)
    .build();
```

```
// Use the configured request with the service client.  
RunInstancesResponse response = ec2Client.runInstances(runInstancesRequest);
```

Rather than create a request and pass in the instance, the SDK provides a fluent API that you can use to create a request. With the fluent API you can use a Java lambda expressions to create the request 'in-line'.

The following example rewrites the previous example by using the version of the `runInstances` [method that uses a builder](#) to create the request.

```
// Create the request by using a lambda expression.  
RunInstancesResponse response = ec2.runInstances(r -> r  
    .imageId(amiId)  
    .instanceType(InstanceType.T1_MICRO)  
    .maxCount(1)  
    .minCount(1));
```

Use requests to override client configuration

Although a service client is immutable, you can override many of its settings at the request level. When you build a request, you can provide an [AwsRequestOverrideConfiguration](#) instance to provide the overridden settings. Some of the methods you can use to override client settings are:

- `apiCallAttemptTimeout`
- `apiCallTimeout`
- `credentialProvider`
- `compressionConfiguration`
- `putHeader`

For an example of overriding a client setting with a request, assume that you have the following S3 client that uses default settings.

```
S3Client s3Client = S3Client.create();
```

You want to download a large file and want to be sure the request doesn't timeout before the download finishes. To accomplish this, increase the timeout values for only a single `GetObject` request as shown in the following code.

Standard API

```
AwsRequestOverrideConfiguration overrideConfiguration =
    AwsRequestOverrideConfiguration.builder()
        .apiCallTimeout(Duration.ofSeconds(100L))
        .apiCallAttemptTimeout(Duration.ofSeconds(25L))
        .build();

GetObjectRequest request = GetObjectRequest.builder()
    .bucket("DOC-EXAMPLE-BUCKET")
    .key("DOC-EXAMPLE-KEY")
    .overrideConfiguration(overrideConfiguration)
    .build();

s3Client.getObject(request, myPath);
```

Fluent API

```
s3Client.getObject(b -> b
    .bucket("DOC-EXAMPLE-BUCKET")
    .key("DOC-EXAMPLE-KEY")
    .overrideConfiguration(c -> c
        .apiCallTimeout(Duration.ofSeconds(100L))
        .apiCallAttemptTimeout(Duration.ofSeconds(25L))),
    myPath);
```

Handle responses

The SDK returns a response object for most service operations. Your code can process the information in the response object according to your needs.

For example, the following code snippet prints out the first instance id returned with the [RunInstancesResponse](#) object from the previous request.

```
RunInstancesResponse runInstancesResponse =
    ec2Client.runInstances(runInstancesRequest);
System.out.println(runInstancesResponse.instances().get(0).instanceId());
```

Not all operations return a response object with service-specific data, however. In these situations, you can query the HTTP response status to learn if the operation was successful.

For example, the code in the following snippet checks the HTTP response to see if the [DeleteContactList](#) operation of Amazon Simple Email Service was successful.

```
SesV2Client sesv2Client = SesV2Client.create();

DeleteContactListRequest request = DeleteContactListRequest.builder()
    .contactListName("ExampleContactListName")
    .build();

DeleteContactListResponse response = sesv2Client.deleteContactList(request);
if (response.sdkHttpResponse().isSuccessful()) {
    System.out.println("Contact list deleted successfully");
} else {
    System.out.println("Failed to delete contact list. Status code: " +
        response.sdkHttpResponse().statusCode());
}
```

Handle exceptions

The SDK uses runtime (or unchecked) exceptions, providing you fine-grained control over error handling and ensuring that exception handling will scale with your application.

An [SdkServiceException](#), or one of its sub-classes, is the most common form of exception the SDK will throw. These exceptions represent responses from the AWS service. You can also handle an [SdkClientException](#), which occurs when there's a problem on the client side (i.e., in your development or application environment), such a network connection failure.

This code snippet demonstrates one way to handle service exceptions when you upload a file to Amazon S3. The example code catches both client and server exceptions, logs the details, and exists the application.

```
Region region = Region.US_WEST_2;
S3Client s3Client = S3Client.builder()
    .region(region)
    .build();

try {

    PutObjectRequest putObjectRequest = PutObjectRequest.builder()
        .bucket(bucketName)
```

```
        .key(key)
        .build();

    s3Client.putObject(putObjectRequest, RequestBody.fromString("SDK for Java test"));
} catch (S3Exception se) {
    System.err.println("Service exception thrown.");
    System.err.println(se.awsErrorDetails().errorMessage());
} catch (SdkClientException ce){
    System.err.println("Client exception thrown.");
    System.err.println(ce.getMessage());
} finally {
    System.exit(1);
}
```

See [Handling exceptions](#) for more information.

Use waiters

Some requests take time to process, such as creating a new table in DynamoDB or creating a new Amazon S3 bucket. To ensure the resource is ready before your code continues to run, use a *Waiter*.

For example, this code snippet creates a new table ("myTable") in DynamoDB, waits for the table to be in an ACTIVE status, and then prints out the response:

```
DynamoDbClient dynamoDbClient = DynamoDbClient.create();
DynamoDbWaiter dynamoDbWaiter = dynamoDbClient.waiter();

WaiterResponse<DescribeTableResponse> waiterResponse =
    dynamoDbWaiter.waitUntilTableExists(r -> r.tableName("myTable"));

waiterResponse.matched().response().ifPresent(System.out::println);
```

See [Using waiters](#) for more information.

Set timeouts

You can configure timeouts for each of your service clients using the [apiCallTimeout](#) and the [apiCallAttemptTimeout](#) setters of the [ClientOverrideConfiguration.Builder](#). The

`apiCallTimeout` setting is the amount of time to allow the client to complete the execution of an API call. The `apiCallAttemptTimeout` setting is the amount of time to wait for each HTTP request (retry) to complete before giving up.

The following example sets both timeouts for an S3 client.

```
S3Client s3Client = S3Client.builder()
    .overrideConfiguration(b -> b
        .apiCallTimeout(Duration.ofSeconds(105L))
        .apiCallAttemptTimeout(Duration.ofSeconds(25L)))
    .build();
```

You can also set timeouts at the request level by configuring an [AwsRequestOverrideConfiguration](#) and providing it to the request object with the `overrideConfiguration` method.

The following example uses the same timeout settings but at the request level for an S3 `PutObject` operation.

```
S3Client basicS3Client = S3Client.create(); // Client with default timeout settings.

AwsRequestOverrideConfiguration overrideConfiguration =
    AwsRequestOverrideConfiguration.builder()
        .apiCallTimeout(Duration.ofSeconds(105L))
        .apiCallAttemptTimeout(Duration.ofSeconds(25L))
        .build();

basicS3Client.putObject(b -> b
    .bucket("DOC-EXAMPLE-BUCKET")
    .key("DOC-EXAMPLE-KEY")
    .overrideConfiguration(overrideConfiguration),
    RequestBody.fromString("test"));
```

Execution interceptors

You can write code that intercepts the execution of your API requests and responses at different parts of the request/response lifecycle. This enables you to publish metrics, modify a request in-flight, debug request processing, view exceptions, and more. For more information, see [the ExecutionInterceptor interface](#) in the AWS SDK for Java API Reference.

Configure SDK authentication

Before making a request to Amazon Web Services using the AWS SDK for Java 2.x, the SDK cryptographically signs temporary credentials issued by AWS. To access temporary credentials, the SDK retrieves configuration values by checking several locations.

This topic discusses several ways that you enable the SDK to access temporary credentials.

Topics

- [Configure access to temporary credentials](#)
- [Default credentials provider chain](#)
- [Use a specific credentials provider](#)
- [Use profiles](#)
- [Load temporary credentials from an external process](#)
- [Supply temporary credentials in code](#)
- [Read IAM role credentials on Amazon EC2](#)

Configure access to temporary credentials

For increased security, AWS recommends that you configure the SDK for Java to [use temporary credentials](#) instead of long-lived credentials. Temporary credentials consist of access keys (access key id and secret access key) and a session token. We recommend that you [configure the SDK](#) to automatically get temporary credentials, since the token refresh process is automatic. You can, however, [provide the SDK with temporary credentials](#) directly.

IAM Identity Center configuration

When you configure the SDK to use IAM Identity Center single sign-on access as described in [???](#) in this guide, the SDK automatically uses temporary credentials.

The SDK uses the IAM Identity Center access token to gain access to the IAM role that is configured with the `sso_role_name` setting in your config file. The SDK assumes this IAM role and retrieves temporary credentials to use for AWS service requests.

For more details about how the SDK gets temporary credentials from the configuration, see the [Understanding IAM Identity Center authentication](#) section of the AWS SDKs and Tools Reference Guide.

Note

In addition to the configuration that you set in the `config` file that works for all projects, each individual Java project requires that the Maven `pom.xml` file contains the following dependencies:

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>sso</artifactId>
</dependency>
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>ssooidc</artifactId>
</dependency>
```

The `sso` and `ssooidc` dependencies provide the code that enables the SDK for Java 2.x to access temporary credentials.

Retrieve from AWS access portal

As an alternative to IAM Identity Center single sign-on configuration, you can copy and use temporary credentials available in the AWS access portal. You can use the temporary credentials in a profile or use them as values for system properties and environment variables.

Set up a local credentials file for temporary credentials

1. [Create a shared credentials file](#)
2. In the credentials file, paste the following placeholder text until you paste in working temporary credentials.

```
[default]
aws_access_key_id=<value from AWS access portal>
aws_secret_access_key=<value from AWS access portal>
aws_session_token=<value from AWS access portal>
```

3. Save the file. The file `~/.aws/credentials` should now exist on your local development system. This file contains the [\[default\] profile](#) that the SDK for Java uses if a specific named profile is not specified.

```
.region(region)
.build();
```

Credential settings retrieval order

The default credentials provider chain of the SDK for Java 2.x searches for configuration in your environment using a predefined sequence.

1. Java system properties

- The SDK uses the [SystemPropertyCredentialsProvider](#) class to load temporary credentials from the `aws.accessKeyId`, `aws.secretAccessKey`, and `aws.sessionToken` Java system properties.

Note

For information on how to set Java system properties, see the [System Properties](#) tutorial on the official *Java Tutorials* website.

2. Environment variables

- The SDK uses the [EnvironmentVariableCredentialsProvider](#) class to load temporary credentials from the `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN` environment variables.

3. Web identity token from AWS Security Token Service

- The SDK uses the [WebIdentityTokenFileCredentialsProvider](#) class to load temporary credentials from Java system properties or environment variables.

4. The shared credentials and config files

- The SDK uses the [ProfileCredentialsProvider](#) to load IAM Identity Center single sign-on settings or temporary credentials from the `[default]` profile in the shared credentials and config files.

The AWS SDKs and Tools Reference Guide has [detailed information](#) about how the SDK for Java works with the IAM Identity Center single sign-on token to get temporary credentials that the SDK uses to call AWS services.

Note

The credentials and config files are shared by various AWS SDKs and Tools. For more information, see [The .aws/credentials and .aws/config files](#) in the AWS SDKs and Tools Reference Guide.

5. Amazon ECS container credentials

- The SDK uses the [ContainerCredentialsProvider](#) class to load temporary credentials from the following environment variables:

AWS_CONTAINER_CREDENTIALS_RELATIVE_URI or
AWS_CONTAINER_CREDENTIALS_FULL_URI

AWS_CONTAINER_AUTHORIZATION_TOKEN_FILE or
AWS_CONTAINER_AUTHORIZATION_TOKEN

6. Amazon EC2 instance IAM role-provided credentials

- The SDK uses the [InstanceProfileCredentialsProvider](#) class to load temporary credentials from the Amazon EC2 metadata service.

Use a specific credentials provider

The SDK uses credentials providers to retrieve, manage, and supply authentication credentials (such as access keys and session tokens) that are needed to access AWS services.

Credential providers simplify retrieving credentials from various sources, implement security best practices, and support flexible authentication strategies across AWS environments.

Specify a credentials provider

To bypass the default credentials provider chain, specify which credentials provider a service client should use. When you supply a specific credentials provider, the SDK skips the process of checking various locations, which slightly reduces the time to create a service client.

For example, if you set your default configuration using environment variables, supply an [EnvironmentVariableCredentialsProvider](#) object to the `credentialsProvider` method on the service client builder, as shown the following code snippet:

```
Region region = Region.US_WEST_2;
```

```
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();
```

For a complete list of credential providers and provider chains, see **All Known Implementing Classes** in the API reference for [AwsCredentialsProvider](#).

Note

You can also use your own credentials provider or provider chains by implementing the `AwsCredentialsProvider` interface.

Configure a credentials provider

As an example of configuring a credentials provider implementation, you might want to have the SDK use a background thread to pre-fetch (retrieve in advance) credentials before they expire. That way you can avoid the blocking call that retrieves fresh credentials.

The following shows an example that creates an [StsAssumeRoleCredentialsProvider](#) that uses a background thread to pre-fetch credentials by setting the [asyncCredentialUpdateEnabled](#) property to true on the builder:

```
S3Client s3Client = S3Client.builder()
    .credentialsProvider(StsAssumeRoleCredentialsProvider.builder()
        .asyncCredentialUpdateEnabled(true)
        .stsClient(StsClient.create())
        .refreshRequest(r -> r
            .roleArn("arn:aws:iam::111122223333:role/S3-listbuckets-only-role")
            .roleSessionName("test-temp-session")
            .durationSeconds(900))
        .build())
    .build();
```

When you invoke an operation on `s3Client` for the first time, an [AssumeRoleRequest](#) is sent to the AWS Security Token Service (STS). STS returns temporary credentials that are valid for 15 minutes (900 seconds). The `s3Client` instance uses the cached credentials until it's time to refresh them before the 15 minutes elapse. By default, the SDK attempts to retrieve new credentials for

a new session between 5 minutes and 1 minute before the expiration time of the current session. The pre-fetch window is configurable by using the [prefetchTime](#) and [staleTime](#) properties.

You can configure the following session-based credentials providers similarly:

- `StsWebIdentityTokenFileCredentialsProvider`
- `StsGetSessionTokenCredentialsProvider`
- `StsGetFederationTokenCredentialsProvider`
- `StsAssumeRoleWithWebIdentityCredentialsProvider`
- `StsAssumeRoleWithSamlCredentialsProvider`
- `StsAssumeRoleCredentialsProvider`
- `DefaultCredentialsProvider` (when it delegates to credentials provider that uses sessions)
- `ProcessCredentialsProvider`
- `WebIdentityTokenFileCredentialsProvider`
- `ContainerCredentialsProvider`
- `InstanceProfileCredentialsProvider`

Use profiles

Using the shared config and credentials file, you can set up several profiles. This enables your application to use multiple sets of credentials configuration. The `[default]` profile was mentioned previously. The SDK uses the [ProfileCredentialsProvider](#) class to load settings from profiles defined in the shared credentials file.

The following code snippet demonstrates how to build a service client that uses the settings defined as part of the profile named `my_profile`.

```
Region region = Region.US_WEST_2;
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .credentialsProvider(ProfileCredentialsProvider.create("my_profile"))
    .build();
```

Set a different profile as the default

To set a profile other than the `[default]` profile as the default for your application, set the `AWS_PROFILE` environment variable to the name of your custom profile.

To set this variable on Linux, macOS, or Unix, use export:

```
export AWS_PROFILE="other_profile"
```

To set these variables on Windows, use set:

```
set AWS_PROFILE="other_profile"
```

Alternatively, set the `aws.profile` Java system property to the name of the profile.

Reload profile credentials

You can configure any credentials provider that has a `profileFile()` method on its builder to reload profile credentials. These credentials profile classes are: `ProfileCredentialsProvider`, `DefaultCredentialsProvider`, `InstanceProfileCredentialsProvider`, and `ProfileTokenProvider`.

Note

Profile credential reloading works only with the following settings in the profile file : `aws_access_key_id`, `aws_secret_access_key`, and `aws_session_token`. Settings such as `region`, `sso_session`, `sso_account_id`, and `source_profile` are ignored.

To configure a supported credentials provider to reload profile settings, provide an instance of [ProfileFileSupplier](#) to the `profileFile()` builder method. The following code example demonstrates a `ProfileCredentialsProvider` that reloads credential settings from the `[default]` profile.

```
ProfileCredentialsProvider provider = ProfileCredentialsProvider
    .builder()
    .profileFile(ProfileFileSupplier.defaultSupplier())
    .build();

// Set up a service client with the provider instance.
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(provider)
    .build();
```

```
/*  
    Before dynamoDbClient makes a request, it reloads the credentials settings  
    by calling provider.resolveCredentials().  
*/
```

When `ProfileCredentialsProvider.resolveCredentials()` is called, the SDK for Java reloads the settings. `ProfileFileSupplier.defaultSupplier()` is one of [several convenience implementations](#) of `ProfileFileSupplier` provided by the SDK. If your use case requires, you can provide your own implementation.

The following example shows the use of the `ProfileFileSupplier.reloadWhenModified()` convenience method. `reloadWhenModified()` takes a `Path` parameter, which gives you flexibility in designating the source file for the configuration rather than the standard `~/.aws/credentials` (or `config`) location.

The settings will be reloaded when `resolveCredentials()` is called only if SDK determines the file's content has been modified.

```
Path credentialsFilePath = ...  
  
ProfileCredentialsProvider provider = ProfileCredentialsProvider  
    .builder()  
    .profileFile(ProfileFileSupplier.reloadWhenModified(credentialsFilePath,  
ProfileFile.Type.CREDENTIALS))  
    .profileName("my-profile")  
    .build();  
/*  
    A service client configured with the provider instance calls  
    provider.resolveCredential()  
    before each request.  
*/
```

The `ProfileFileSupplier.aggregate()` method merges the contents of multiple configuration files. You decide whether a file is reloaded per call to `resolveCredentials()` or a file's settings are fixed at the time it was first read.

The following example shows a `DefaultCredentialsProvider` that merges the settings of two files that contain profile settings. The SDK reloads the settings in the file pointed to by the `credentialsFilePath` variable each time `resolveCredentials()` is called and the settings have changed. The settings from the `profileFile` object remain the same.

```
Path credentialsFilePath = ...;
ProfileFile profileFile = ...;

DefaultCredentialsProvider provider = DefaultCredentialsProvider
    .builder()
    .profileFile(ProfileFileSupplier.aggregate(
        ProfileFileSupplier.reloadWhenModified(credentialsFilePath,
ProfileFile.Type.CREDENTIALS),
        ProfileFileSupplier.fixedProfileFile(profileFile)))
    .profileName("my-profile")
    .build();

/*
   A service client configured with the provider instance calls
   provider.resolveCredential()
   before each request.
*/
```

Load temporary credentials from an external process

Warning

The following describes a method of sourcing temporary credentials from an external process. This can potentially be dangerous, so proceed with caution. Other credential providers should be preferred if at all possible. If using this option, you should make sure that the config file is as locked down as possible using security best practices for your operating system.

Make sure that your custom credentials tool does not write any secret information to `StdErr`. SDKs and AWS CLI can capture and log such information, potentially exposing it to unauthorized users.

With the SDK for Java 2.x, you can acquire temporary credentials from an external process for custom use cases. There are two ways to configure this functionality.

Use the `credential_process` setting

If you have a method that provides temporary credentials, you can integrate it by adding the `credential_process` setting as part of a profile definition in the config file. The value you specify must use the full path to the command file. If the file path contains any spaces, you must surround it with quotation marks.

The SDK calls the command exactly as given and then reads JSON data from stdout.

The following examples show the use of this setting for file paths without spaces and file paths with spaces.

Linux/macOS

No spaces in file path

```
[profile process-credential-profile]
credential_process = /path/to/credential/file/credential_file.sh --custom-command
custom_parameter
```

Spaces in file path

```
[profile process-credential-profile]
credential_process = "/path/with/space to/credential/file/credential_file.sh" --
custom-command custom_parameter
```

Windows

No spaces in file path

```
[profile process-credential-profile]
credential_process = C:\Path\To\credentials.cmd --custom_command custom_parameter
```

Spaces in file path

```
[profile process-credential-profile]
credential_process = "C:\Path\With Space To\credentials.cmd" --custom_command
custom_parameter
```

The following code snippet demonstrates how to build a service client that uses the temporary credentials defined as part of the profile named `process-credential-profile`.

```
Region region = Region.US_WEST_2;
S3Client s3Client = S3Client.builder()
    .region(region)
    .credentialsProvider(ProfileCredentialsProvider.create("process-credential-
profile"))
```

```
.build();
```

For detailed information about using an external process as a source of temporary credentials, refer to the [process credentials section](#) in the AWS SDKs and Tools Reference Guide.

Use a `ProcessCredentialsProvider`

As an alternative to using settings in the config file, you can use the SDK's [ProcessCredentialsProvider](#) to load temporary credentials using Java.

The following examples show various versions of how to specify an external process using the `ProcessCredentialsProvider` and configuring a service client that uses the temporary credentials.

Linux/macOS

No spaces in file path

```
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("/path/to/credentials.sh optional_param1 optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();
```

Spaces in file path

```
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("/path\\ with\\ spaces\\ to/credentials.sh optional_param1
optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
```

```
.build();
```

Windows

No spaces in file path

```
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("C:\\Path\\To\\credentials.exe optional_param1 optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();
```

Spaces in file path

```
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("\"C:\\Path\\With Spaces To\\credentials.exe\" optional_param1
optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();
```

Use IAM Roles Anywhere for authentication

[IAM Roles Anywhere](#) is an AWS service that allows you to obtain temporary AWS credentials for workloads running outside of AWS. It enables secure access to AWS resources from on-premises or other cloud environments.

Before you can authenticate requests with IAM Roles Anywhere, you first need to gather the required information and download the [credential helper tool](#). By following the [Getting started](#) instructions in the IAM Roles Anywhere User Guide, you can create the necessary artifacts.

The SDK for Java doesn't have a dedicated credentials provider to retrieve temporary credentials from IAM Roles Anywhere, but you can use the credential helper tool along with one of the options to [retrieve credentials from an external process](#).

Use the `credential_process` setting in a profile

The following snippet in the shared AWS config file shows a profile named `roles_anywhere` that uses the `credential_process` setting:

```
[profile roles_anywhere]
credential_process = ./aws_signing_helper credential-process \
  --certificate /path/to/certificate \
  --private-key /path/to/private-key \
  --trust-anchor-arn arn:aws:rolesanywhere:region:account:trust-anchor/TA_ID \
  --profile-arn arn:aws:rolesanywhere:region:account:profile/PROFILE_ID \
  --role-arn arn:aws:iam:account:role/role-name-with-path
```

You need to replace the text shown in red with your values after you have assembled all the artifacts. The first element in the setting, `aws_signing_helper`, is the executable of the credential helper tool and `credential-process` is the command.

When you configure a service client to use the `roles_anywhere` profile—as shown in the following code—the SDK caches the temporary credentials and refreshes them before they expire:

```
S3Client s3Client = S3Client.builder()
    .credentialsProvider(ProfileCredentialsProvider.builder()
        .profileName("roles_anywhere").build())
    .build();
```

Configure a `ProcessCredentialsProvider`

As shown next, you can use a code-only approach with the `ProcessCredentialsProvider` instead of using profile settings:

```
ProcessCredentialsProvider processCredentialsProvider =
    ProcessCredentialsProvider.builder()
        .command("""
            ./aws_signing_helper credential-process \
            --certificate /path/to/certificate \
            --private-key /path/to/private-key \
            --trust-anchor-arn arn:aws:rolesanywhere:region:account:trust-anchor/TA_ID
        """)
        .build();
```

```

        --profile-arn arn:aws:rolesanywhere:region:account:profile/PROFILE_ID \
        --role-arn arn:aws:iam::account:role/role-name-with-path
        """).build();

```

```

S3Client s3Client = S3Client.builder()
    .credentialsProvider(processCredentialsProvider)
    .build();

```

Replace the text shown in red with your values after you have assembled all the artifacts.

Supply temporary credentials in code

If the default credential chain or a specific or custom provider or provider chain doesn't work for your application, you can supply temporary credentials directly in code. These can be [IAM role credentials](#) as [described above](#) or temporary credentials retrieved from AWS Security Token Service (AWS STS). If you retrieved temporary credentials using AWS STS, provide them to an AWS service client as shown in the following code example.

1. Assume a role by calling `StsClient.assumeRole()`.
2. Create a [StaticCredentialsProvider](#) object and supply it with the `AwsSessionCredentials` object.
3. Configure the service client builder with the `StaticCredentialsProvider` and build the client.

The following example creates an Amazon S3 service client using temporary credentials returned by AWS STS for an IAM assumed role.

```

// The AWS IAM Identity Center identity (user) who executes this method does not
// have permission to list buckets.
// The identity is configured in the [default] profile.
public static void assumeRole(String roleArn, String roleSessionName) {
    // The IAM role represented by the 'roleArn' parameter can be assumed by
    // identities in two different accounts
    // and the role permits the user to only list buckets.

    // The SDK's default credentials provider chain will find the single sign-on
    // settings in the [default] profile.
    // The identity configured with the [default] profile needs permission to call
    // AssumeRole on the STS service.
    try {

```

```

    Credentials tempRoleCredentials;
    try (StsClient stsClient = StsClient.create()) {
        AssumeRoleRequest roleRequest = AssumeRoleRequest.builder()
            .roleArn(roleArn)
            .roleSessionName(roleSessionName)
            .build();

        AssumeRoleResponse roleResponse = stsClient.assumeRole(roleRequest);
        tempRoleCredentials = roleResponse.credentials();
    }
    // Use the following temporary credential items for the S3 client.
    String key = tempRoleCredentials.accessKeyId();
    String secKey = tempRoleCredentials.secretAccessKey();
    String secToken = tempRoleCredentials.sessionToken();

    // List all buckets in the account associated with the assumed role
    // by using the temporary credentials retrieved by invoking
    stsClient.assumeRole().
        StaticCredentialsProvider staticCredentialsProvider =
        StaticCredentialsProvider.create(
            AwsSessionCredentials.create(key, secKey, secToken));
    try (S3Client s3 = S3Client.builder()
        .credentialsProvider(staticCredentialsProvider)
        .build()) {
        List<Bucket> buckets = s3.listBuckets().buckets();
        for (Bucket bucket : buckets) {
            System.out.println("bucket name: " + bucket.name());
        }
    }
} catch (StsException | S3Exception e) {
    logger.error(e.getMessage());
    System.exit(1);
}
}

```

Permission set

The following permission set defined in AWS IAM Identity Center allows the identity (user) to perform the following two operations

1. The `GetObject` operation of the Amazon Simple Storage Service.
2. The `AssumeRole` operation of the AWS Security Token Service.

Without assuming the role, the `s3.listBuckets()` method shown in the example would fail.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "sts:AssumeRole"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Assumed role

Assumed role permissions policy

The following permissions policy is attached to the role that is assumed in the previous example. This permissions policy permits the ability to list all buckets in the same account as the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListAllMyBuckets"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Assumed role trust policy

The following trust policy is attached to the role that is assumed in the previous example. The policy allows the role to be assumed by identities (users) in two accounts.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::111122223333:root",
          "arn:aws:iam::555555555555:root"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {}
    }
  ]
}
```

Read IAM role credentials on Amazon EC2

You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Use an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

This topic provides information on how to set up your Java application to run on an EC2 instance and enable the SDK for Java to acquire IAM role credentials.

Acquire IAM role credentials from the environment

If your application creates an AWS service client by using the `create` method (or `builder().build()` methods), the SDK for Java uses the *default credentials provider chain*. The default credentials provider chain searches the execution environment for configuration elements

that the SDK can trade for temporary credentials. The [the section called “Default credentials provider chain”](#) section describes the full search process.

The final step in the default provider chain is available only when your application runs on an Amazon EC2 instance. In this step, the SDK uses an `InstanceProfileCredentialsProvider` to read the IAM role defined in the EC2 instance profile. The SDK then acquires temporary credentials for that IAM role.

Although these credentials are temporary and would eventually expire, an `InstanceProfileCredentialsProvider` periodically refreshes them for you so that they continue to allow access to AWS.

Acquire IAM role credentials programmatically

As an alternative to the default credentials provider chain that eventually uses an `InstanceProfileCredentialsProvider` on EC2, you can configure a service client explicitly with an `InstanceProfileCredentialsProvider`. This approach is shown in the following snippet.

```
S3Client s3 = S3Client.builder()
    .credentialsProvider(InstanceProfileCredentialsProvider.create())
    .build();
```

Securely acquire IAM role credentials

By default, EC2 instances run [IMDS](#) (Instance Metadata Service) that allows the SDK's `InstanceProfileCredentialsProvider` to access information such as the IAM role that has been configured. EC2 instances run two versions of IMDS by default:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

[IMDSv2 is a more secure approach](#) than IMDSv1.

By default, the Java SDK first tries IMDSv2 to get the IAM role, but if that fails, it tries IMDSv1. However, since IMDSv1 is less secure, AWS recommends the use of IMDSv2 only and to disable the SDK from trying IMDSv1.

To use the more secure approach, disable the SDK from using IMDSv1 by providing one of the following settings with a value of `true`.

- Environment variable: `AWS_EC2_METADATA_V1_DISABLED`
- JVM system property: `aws.disableEc2MetadataV1`
- Shared config file setting: `ec2_metadata_v1_disabled`

With one of these settings set to `true`, the SDK does not load IMDS role credentials by using IMDSv1 if the initial IMDSv2 call fails.

Use AWS Regions

AWS Regions enable service clients to access AWS services that physically resides in a specific geographic area.

Explicitly configure an AWS Region

To explicitly set a Region, we recommend that you use the constants defined in the [Region](#) class. This is an enumeration of all publicly available regions.

To create a client with an enumerated Region from the class, use the client builder's `region` method.

```
Ec2Client ec2 = Ec2Client.builder()
    .region(Region.US_WEST_2)
    .build();
```

If the Region you want to use isn't one of the enumerations in the `Region` class, you can create a new Region by using the static `of` method. This method allows you access to new Regions without upgrading the SDK.

```
Region newRegion = Region.of("us-east-42");
Ec2Client ec2 = Ec2Client.builder()
    .region(newRegion)
    .build();
```

Note

After you build a client with the builder, it's *immutable* and the AWS Region *cannot be changed*. If you need to work with multiple AWS Regions for the same service, you should create multiple clients—one per Region.

Let the SDK automatically determine the Region from the environment

When your code runs on Amazon EC2 or AWS Lambda, you might want to configure clients to use the same AWS Region that your code is running on. This decouples your code from the environment it's running in and makes it easier to deploy your application to multiple AWS Regions for lower latency or redundancy.

To use the default credential/region provider chain to determine the Region from the environment, use the client builder's `create` method.

```
Ec2Client ec2 = Ec2Client.create();
```

If you don't explicitly set an AWS Region by using the `region` method, the SDK consults the default region provider chain to determine the Region to use.

Understand the default region provider chain

The SDK takes the following steps to look for an AWS Region :

1. Any explicit Region set by using `region` on the builder itself takes precedence over anything else.
2. The `AWS_REGION` environment variable is checked. If it's set, that Region is used to configure the client.

Note

The Lambda container sets this environment variable.

3. The SDK checks the AWS shared configuration file and shared credentials file (usually located at `~/.aws/config` and `~/.aws/credentials`). If the `region` property is present, the SDK uses it.
 - If the SDK finds the `region` property in both files for the same profile (including the default profile), the SDK uses the value in the shared credentials file.
 - The `AWS_CONFIG_FILE` environment variable can be used to customize the location of the shared config file.
 - The `AWS_PROFILE` environment variable or the `aws.profile` system property can be used to specify the profile that the SDK loads.

- The SDK attempts to use the Amazon EC2 instance metadata service (IMDS) to determine the Region of the currently running Amazon EC2 instance.
 - For greater security, you should disable the SDK from attempting to use version 1 of IMDS. You use the same setting to disable version 1 that are described in the [the section called “Securely”](#) section.
- If the SDK still hasn't found a Region by this point, client creation fails with an exception.

When developing AWS applications, a common approach is to use the *shared configuration file* (described in [Credential retrieval order](#)) to set the Region for local development, and rely on the default region provider chain to determine the Region when the application runs on AWS infrastructure. This greatly simplifies client creation and keeps your application portable.

Check for service availability in a Region

To see if a particular AWS service is available in a Region, use the `serviceMetadata` and `region` method on the service client.

```
DynamoDbClient.serviceMetadata().regions().forEach(System.out::println);
```

See the [Region](#) class documentation for the AWS Regions you can specify, and use the endpoint prefix of the service to query.

Choose a specific endpoint

In certain situations—such as to test preview features of a service before the features graduate to general availability—you may need to specify a specific endpoint in a Region. In these situations, service clients can be configured by calling the `endpointOverride` method.

For example, to configure an Amazon EC2 client to use the Europe (Ireland) Region with a specific endpoint, use the following code.

```
Ec2Client ec2 = Ec2Client.builder()  
    .region(Region.EU_WEST_1)  
    .endpointOverride(URI.create("https://ec2.eu-west-1.amazonaws.com"))  
    .build();
```

See [Regions and Endpoints](#) for the current list of regions and their corresponding endpoints for all AWS services.

Reduce SDK startup time for AWS Lambda

One of the goals of the AWS SDK for Java 2.x is to reduce the startup latency for AWS Lambda functions. The SDK contains changes that reduce startup time, which are discussed at the end of this topic.

First, this topic focuses on changes that you can make to reduce cold start times. These include making changes in your code structure and in the configuration of service clients.

Use an AWS CRT-based HTTP client

For working with AWS Lambda, we recommend the [AwsCrtHttpClient](#) for synchronous scenarios and the [AwsCrtAsyncHttpClient](#) for asynchronous scenarios.

The [the section called “Configure AWS CRT-based HTTP clients”](#) topic in this guide describes the benefits of using the HTTP clients, how to add the dependency, and how configure their use by service clients.

Remove unused HTTP client dependencies

Along with the explicit use of an AWS CRT-based client, you can remove other HTTP clients that the SDK brings in by default. Lambda startup time is reduced when fewer libraries need to be loaded, so you should remove any unused artifacts that the JVM needs to load.

The following snippet of a Maven `pom.xml` file shows the exclusion of the Apache-based HTTP client and the Netty-based HTTP client. (These clients aren't needed when you use an AWS CRT-based client.) This example excludes the HTTP client artifacts from the S3 client dependency and adds the `aws-crt-client` artifact to allow access to the AWS CRT-based HTTP clients.

```
<project>
  <properties>
    <aws.java.sdk.version>2.27.21</aws.java.sdk.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.java.sdk.version}</version>
        <type>pom</type>
      </dependency>
    </dependencies>
  </dependencyManagement>
</project>
```

```
        <scope>import</scope>
    </dependency>
</dependencies>
</dependencyManagement>
<dependencies>
    <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>aws-crt-client</artifactId>
    </dependency>
    <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>s3</artifactId>
        <exclusions>
            <exclusion>
                <groupId>software.amazon.awssdk</groupId>
                <artifactId>netty-nio-client</artifactId>
            </exclusion>
            <exclusion>
                <groupId>software.amazon.awssdk</groupId>
                <artifactId>apache-client</artifactId>
            </exclusion>
        </exclusions>
    </dependency>
</dependencies>
</project>
```

Note

Add the `<exclusions>` element to all service client dependencies in your `pom.xml` file.

Configure service clients to shortcut lookups

Specify a region

When you create a service client, call the `region` method on the service client builder. This shortcuts the SDK's default [Region lookup process](#) that checks several places for the AWS Region information.

To keep the Lambda code independent of the region, use the following code inside the `region` method. This code accesses the `AWS_REGION` environment variable set by the Lambda container.

```
Region.of(System.getenv(SdkSystemSetting.AWS_REGION.environmentVariable()))
```

Use the `EnvironmentVariableCredentialProvider`

Much like the default lookup behavior for the Region information, the SDK looks in several places for credentials. By specifying the [EnvironmentVariableCredentialProvider](#) when you build a service client, you save time in the SDK's lookup process for credentials.

Note

Using this credentials provider enables the code to be used in Lambda functions, but might not work on Amazon EC2 or other systems.

If you intend to use [Lambda SnapStart for Java](#) at some point, you should rely on the default credentials provider chain to lookup credentials. If you specify the `EnvironmentVariableCredentialsProvider`, the initial credentials lookup works, but when SnapStart is activated, [the Java runtime sets container credentials environment variables](#). On activation, the environment variables used by the `EnvironmentVariableCredentialsProvider`—access key environment variables—are not available to the Java SDK.

The following code snippet shows an S3 service client appropriately configured for use in a Lambda environment.

```
S3Client s3Client = S3Client.builder()

    .region(Region.of(System.getenv(SdkSystemSetting.AWS_REGION.environmentVariable())))
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .httpClient(AwsCrtHttpClient.builder().build())
    .build();
```

Initialize the SDK client outside of the Lambda function handler

We recommend initializing an SDK client outside of the Lambda handler method. This way, if the execution context is reused, the initialization of the service client can be skipped. By reusing the client instance and its connections, subsequent invocations of the handler method occur more quickly.

In the following example, the `S3Client` instance is initialized in the constructor using a static factory method. If the container that is managed by the Lambda environment is reused, the initialized `S3Client` instance is reused.

```
public class App implements RequestHandler<Object, Object> {
    private final S3Client s3Client;

    public App() {
        s3Client = DependencyFactory.s3Client();
    }

    @Override
    public Object handle Request(final Object input, final Context context) {
        ListBucketResponse response = s3Client.listBuckets();
        // Process the response.
    }
}
```

Minimize dependency injection

Dependency injection (DI) frameworks might take additional time to complete the setup process. They might also require additional dependencies, which take time to load.

If a DI framework is needed, we recommend using lightweight DI frameworks such as [Dagger](#).

Use a Maven Archetype targeting AWS Lambda

The AWS Java SDK team has developed a [Maven Archetype](#) template to bootstrap a Lambda project with minimal startup time. You can build out a Maven project from the archetype and know that the dependencies are configured suitably for the Lambda environment.

To learn more about the archetype and work through an example deployment, see this [blog post](#).

Consider Lambda SnapStart for Java

If your runtime requirements are compatible, AWS offers [Lambda SnapStart for Java](#). Lambda SnapStart is an infrastructure-based solution that improves startup performance for Java functions. When you publish a new version of a function, Lambda SnapStart initializes it and takes an immutable, encrypted snapshot of the memory and disk state. SnapStart then caches the snapshot for reuse.

Version 2.x changes that affect startup time

In addition to changes that you make to your code, version 2.x of the SDK for Java includes three primary changes that reduce startup time:

- Use of [jackson-jr](#), which is a serialization library that improves initialization time
- Use of the [java.time](#) libraries for date and time objects, which is part of the JDK
- Use of [Slf4j](#) for a logging facade

Additional resources

The AWS Lambda Developer Guide contains a [section on best practices](#) for developing Lambda functions that is not Java specific.

For an example of building a cloud-native application in Java that uses AWS Lambda, see this [workshop content](#). The workshop discussion performance optimization and other best practices.

You can consider using static images that are compiled ahead of time to reduce startup latency. For example, you can use the SDK for Java 2.x and Maven to [build a GraalVM native image](#).

HTTP clients

You can change the HTTP client to use for your service client as well as change the default configuration for HTTP clients with the AWS SDK for Java 2.x. This section discusses HTTP clients and settings for the SDK.

HTTP clients available in the SDK for Java

Synchronous clients

Synchronous HTTP clients in the SDK for Java implement the [SdkHttpClient](#) interface. A synchronous service client, such as the `S3Client` or the `DynamoDbClient`, requires the use of a synchronous HTTP client. The AWS SDK for Java offers three synchronous HTTP clients.

ApacheHttpClient (default)

[ApacheHttpClient](#) is the default HTTP client for synchronous service clients. For information about configuring the `ApacheHttpClient`, see [Configure the Apache-based HTTP client](#).

AwsCrtHttpClient

[AwsCrtHttpClient](#) provides high throughput and non-blocking IO. It is built on the AWS Common Runtime (CRT) Http Client. For information about configuring the `AwsCrtHttpClient` and using it with service clients, see [the section called “Configure AWS CRT-based HTTP clients”](#).

URLConnectionHttpClient

To minimize the number of jars and third-party libraries your application uses, you can use the [URLConnectionHttpClient](#). For information about configuring the `URLConnectionHttpClient`, see [Configure the URLConnection-based HTTP client](#).

Asynchronous clients

Asynchronous HTTP clients in the SDK for Java implement the [SdkAsyncHttpClient](#) interface. An asynchronous service client, such as the `S3AsyncClient` or the `DynamoDbAsyncClient`, requires the use of an asynchronous HTTP client. The AWS SDK for Java offers two asynchronous HTTP clients.

NettyNioAsyncHttpClient (default)

[NettyNioAsyncHttpClient](#) is the default HTTP client used by asynchronous clients. For information about configuring the `NettyNioAsyncHttpClient`, see [the section called “Configure the Netty-based HTTP client”](#).

AwsCrtAsyncHttpClient

The [AwsCrtAsyncHttpClient](#) is based on the AWS Common Runtime (CRT) HTTP Client. For information about configuring the `AwsCrtAsyncHttpClient`, see [the section called “Configure AWS CRT-based HTTP clients”](#).

HTTP client recommendations

Several factors come into play when you choose an HTTP client implementation. Use the following information to help you decide.

Recommendation flowchart

The following flowchart provides general guidance to help you determine which HTTP client to use.

HTTP client comparison

The following table provides detailed information for each HTTP client.

HTTP client	Sync or async	When to use	Limitation/ drawback
Apache-based HTTP client <i>(default sync HTTP client)</i>	Sync	Use it if you prefer low latency over high throughput	Slower startup time compared to other HTTP clients
URLConnection-based HTTP client	Sync	Use it if you have a hard requirement for limiting third-party dependencies	Does not support the HTTP PATCH method, required by some APIs like Amazon API Gateway Update operations
AWS CRT-based sync HTTP client ¹	Sync	<ul style="list-style-type: none"> • Use it if your application is running in AWS Lambda • Use it if you prefer high throughput over low latency • Use it if you prefer sync SDK clients 	<p>The following Java system properties are not supported:</p> <ul style="list-style-type: none"> • javax.net.ssl.keyStore • javax.net.ssl.keyStorePassword • javax.net.ssl.trustStore • javax.net.ssl.trus

HTTP client	Sync or async	When to use	Limitation/ drawback
			tStorePas sword
Netty-based HTTP client <i>(default async HTTP client)</i>	Async	<ul style="list-style-type: none">• Use it if your application invokes APIs that require HTTP/2 support such as Kinesis API SubscribeToShard	Slower startup time compared to other HTTP clients

HTTP client	Sync or async	When to use	Limitation/ drawback
AWS CRT-based async HTTP client ¹	Async	<ul style="list-style-type: none"> • Use it if your application is running in AWS Lambda • Use it if you prefer high throughput over low latency • Use it if you prefer async SDK clients 	<ul style="list-style-type: none"> • Does not support service clients that require HTTP/2 support such as <code>KinesisAsyncClient</code> and <code>TranscribeStreamingAsyncClient</code> <p>The following Java system properties are not supported:</p> <ul style="list-style-type: none"> • <code>javax.net.ssl.keyStore</code> • <code>javax.net.ssl.keyStorePassword</code> • <code>javax.net.ssl.trustStore</code> • <code>javax.net.ssl.trustStorePassword</code>

¹Because of their added benefits, we recommend that you use the AWS CRT-based HTTP clients if possible.

Smart configuration defaults

The AWS SDK for Java 2.x (version 2.17.102 or later) offers a smart configuration defaults feature. This feature optimizes two HTTP client properties along with other properties that don't affect the HTTP client.

The smart configuration defaults set sensible values for the `connectTimeoutInMillis` and `tlsNegotiationTimeoutInMillis` properties based on a defaults mode value that you provide. You choose the defaults mode value based on your application's characteristics.

For more information about smart configuration defaults and how to choose the defaults mode value that is best suited for your applications, see the [AWS SDKs and Tools Reference Guide](#).

Following are four ways to set the defaults mode for your application.

Service client

Use the service client builder to configure the defaults mode directly on the service client. The following example sets the defaults mode to auto for the `DynamoDbClient`.

```
DynamoDbClient ddbClient = DynamoDbClient.builder()
    .defaultsMode(DefaultsMode.AUTO)
    .build();
```

System property

You can use the `aws.defaultsMode` system property to specify the defaults mode. If you set the system property in Java, you need to set the property before initializing any service client.

The following example shows you how to set the defaults mode to auto using a system property set in Java.

```
System.setProperty("aws.defaultsMode", "auto");
```

The following example demonstrates how you set the defaults mode to auto using a `-D` option of the `java` command.

```
java -Daws.defaultsMode=auto
```

Environment variable

Set a value for environment variable `AWS_DEFAULTS_MODE` to select the defaults mode for your application.

The following information shows the command to run to set the value for the defaults mode to auto using an environment variable.

Operating system	Command to set environment variables
Linux, macOS, or Unix	<code>export AWS_DEFAULTS_MODE=auto</code>
Windows	<code>set AWS_DEFAULTS_MODE=auto</code>

AWS config file

You can add a `defaults_mode` configuration property to the shared AWS config file as the following example shows.

```
[default]
defaults_mode = auto
```

If you set the defaults mode globally with the system property, environment variable, or AWS config file, you can override the settings when you build an HTTP client.

When you build an HTTP client with the `httpClientBuilder()` method, settings apply only to the instance that you are building. An example of this is shown [here](#). The Netty-based HTTP client in this example overrides any default mode values set globally for `connectTimeoutInMillis` and `tlsNegotiationTimeoutInMillis`.

Configure the Apache-based HTTP client

Synchronous service clients in the AWS SDK for Java 2.x use an Apache-based HTTP client, [ApacheHttpClient](#) by default. The SDK's `ApacheHttpClient` is based on the Apache [HttpClient](#).

The SDK also offers the [URLConnectionHttpClient](#), which loads more quickly, but has fewer features. For information about configuring the `URLConnectionHttpClient`, see [the section called "Configure the URLConnection-based HTTP client"](#).

To see the full set of configuration options available to you for the `ApacheHttpClient`, see [ApacheHttpClient.Builder](#) and [ProxyConfiguration.Builder](#).

Access the ApacheHttpClient

In most situations, you use the `ApacheHttpClient` without any explicit configuration. You declare your service clients and the SDK will configure the `ApacheHttpClient` with standard values for you.

If you want to explicitly configure the `ApacheHttpClient` or use it with multiple service clients, you need to make it available for configuration.

No configuration needed

When you declare a dependency on a service client in Maven, the SDK adds a *runtime* dependency on the `apache-client` artifact. This makes the `ApacheHttpClient` class available to your code at runtime, but not at compile time. If you are not configuring the Apache-based HTTP client, you do not need to specify a dependency for it.

In the following XML snippet of a Maven `pom.xml` file, the dependency declared with `<artifactId>s3</artifactId>` automatically brings in the Apache-based HTTP client. You don't need to declare a dependency specifically for it.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.27.21</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <!-- The s3 dependency automatically adds a runtime dependency on the
  ApacheHttpClient-->
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>s3</artifactId>
  </dependency>
</dependencies>
```

With these dependencies, you cannot make any explicit HTTP configuration changes, because the `ApacheHttpClient` library is only on the runtime classpath.

Configuration needed

To configure the `ApacheHttpClient`, you need to add a dependency on the `apache-client` library at *compile* time.

Refer to the following example of a Maven `pom.xml` file to configure the `ApacheHttpClient`.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.27.21</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>s3</artifactId>
  </dependency>
  <!-- By adding the apache-client dependency, ApacheHttpClient will be added to
       the compile classpath so you can configure it. -->
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>apache-client</artifactId>
  </dependency>
</dependencies>
```

Use and configure the `ApacheHttpClient`

You can configure an instance of `ApacheHttpClient` along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the [`ApacheHttpClient.Builder`](#) to configure the properties for the Apache-based HTTP client.

Best practice: dedicate an `ApacheHttpClient` instance to a service client

If you need to configure an instance of the `ApacheHttpClient`, we recommend that you build the dedicated `ApacheHttpClient` instance. You can do so by using the `httpClientBuilder` method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the `ApacheHttpClient` instance is not closed down when it's no longer needed.

The following example creates an `S3Client` and configures the embedded instance of `ApacheHttpClient` with `maxConnections` and `connectionTimeout` values. The HTTP instance is created using the `httpClientBuilder` method of `S3Client.Builder`.

Imports

```
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

Code

```
S3Client s3Client = S3Client // Singleton: Use the s3Client for all requests.
    .builder()
    .httpClientBuilder(ApacheHttpClient.builder()
        .maxConnections(100)
        .connectionTimeout(Duration.ofSeconds(5))
    ).build();

// Perform work with the s3Client.

s3Client.close(); // Requests completed: Close all service clients.
```

Alternative approach: share an `ApacheHttpClient` instance

To help keep resource and memory usage lower for your application, you can configure an `ApacheHttpClient` and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

Note

When an `ApacheHttpClient` instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an Apache-based HTTP client that is used by two service clients. The configured `ApacheHttpClient` instance is passed to the `httpClient` method of each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

Imports

```
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
```

Code

```
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .maxConnections(100).build();

// Singletons: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client =
    S3Client.builder()
        .httpClient(apacheHttpClient).build();

DynamoDbClient dynamoDbClient =
    DynamoDbClient.builder()
        .httpClient(apacheHttpClient).build();

// Perform work with the s3Client and dynamoDbClient.

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
apacheHttpClient.close(); // Explicitly close apacheHttpClient.
```

Proxy configuration example

The following code snippet uses the [proxy configuration builder for the Apache HTTP client](#).

```
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://example.com:1234"))
        .username("username")
        .password("password")
        .addNonProxyHost("localhost")
        .addNonProxyHost("host.example.com")
        .build())
    .build();
```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```
$ java -Dhttp.proxyHost=example.com -Dhttp.proxyPort=1234 -Dhttp.proxyUser=username \
-Dhttp.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ...
App
```

The equivalent setup that uses environment variables is:

```
// Set the following environment variables.
// $ export HTTP_PROXY="http://username:password@example.com:1234"
// $ export NO_PROXY="localhost|host.example.com"

// Set the 'useSystemPropertyValues' to false on the proxy configuration.
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .useSystemPropertyValues(Boolean.FALSE)
        .build())
    .build();

// Run the application.
// $ java -cp ... App
```

Note

The Apache HTTP client does not currently support HTTPS proxy system properties or the `HTTPS_PROXY` environment variable.

Configure the `URLConnection`-based HTTP client

The AWS SDK for Java 2.x offers a lighter-weight [`URLConnectionHttpClient`](#) HTTP client in comparison to the default `ApacheHttpClient`. The `URLConnectionHttpClient` is based on Java's [`URLConnection`](#).

The `URLConnectionHttpClient` loads more quickly than the Apache-based HTTP client, but has fewer features. Because it loads more quickly, it is a [good solution](#) for Java AWS Lambda functions.

The `URLConnectionHttpClient` has several [configurable options](#) that you can access.

Note

The `URLConnectionHttpClient` does not support the HTTP PATCH method. A handful of AWS API operations require PATCH requests. Those operation names usually start with `Update*`. The following are several examples.

- [Several `Update*` operations](#) in the AWS Security Hub API and also the [`BatchUpdateFindings`](#) operation
- All Amazon API Gateway API [`Update*` operations](#)
- [Several `Update*` operations](#) in the Amazon WorkDocs API

If you might use the `URLConnectionHttpClient`, first refer to the API Reference for the AWS service that you're using. Check to see if the operations you need use the PATCH operation.

Access the `URLConnectionHttpClient`

To configure and use the `URLConnectionHttpClient`, you declare a dependency on the `url-connection-client` Maven artifact in your `pom.xml` file.

Unlike the `ApacheHttpClient`, the `URLConnectionHttpClient` is not automatically added to your project, so you must specifically declare it.

The following example of a `pom.xml` file shows the dependencies required to use and configure the HTTP client.

```
<dependencyManagement>
```

```
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>bom</artifactId>
    <version>2.27.21</version>
    <type>pom</type>
    <scope>import</scope>
  </dependency>
</dependencies>
</dependencyManagement>

<!-- other dependencies such as s3 or dynamodb -->

<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>url-connection-client</artifactId>
  </dependency>
</dependencies>
```

Use and configure the `URLConnectionHttpClient`

You can configure an instance of `URLConnectionHttpClient` along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the [URLConnectionHttpClient.Builder](#) to configure the properties for the `URLConnection`-based HTTP client.

Best practice: dedicate an `URLConnectionHttpClient` instance to a service client

If you need to configure an instance of the `URLConnectionHttpClient`, we recommend that you build the dedicated `URLConnectionHttpClient` instance. You can do so by using the `httpClientBuilder` method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the `URLConnectionHttpClient` instance is not closed down when it's no longer needed.

The following example creates an `S3Client` and configures the embedded instance of `URLConnectionHttpClient` with `socketTimeout` and `proxyConfiguration` values. The `proxyConfiguration` method takes a Java lambda expression of type `Consumer` <[ProxyConfiguration.Builder](#)>.

Imports

```
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.urlconnection.UrlConnectionHttpClient;
import java.net.URI;
import java.time.Duration;
```

Code

```
// Singleton: Use the s3Client for all requests.
S3Client s3Client =
    S3Client.builder()
        .httpClientBuilder(UrlConnectionHttpClient.builder()
            .socketTimeout(Duration.ofMinutes(5))
            .proxyConfiguration(proxy -> proxy.endpoint(URI.create("http://
proxy.mydomain.net:8888"))))
        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
        .build();

// Perform work with the s3Client.

s3Client.close(); // Requests completed: Close the s3client.
```

Alternative approach: share an `UrlConnectionHttpClient` instance

To help keep resource and memory usage lower for your application, you can configure an `UrlConnectionHttpClient` and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

Note

When an `UrlConnectionHttpClient` instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an `URLConnection`-based HTTP client that is used by two service clients. The configured `UrlConnectionHttpClient` instance is passed to the `httpClient` method of each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

Imports

```
import software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
```

```
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.urlconnection.ProxyConfiguration;
import software.amazon.awssdk.http.urlconnection.UrlConnectionHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.net.URI;
import java.time.Duration;
```

Code

```
SdkHttpClient urlHttpClient = UrlConnectionHttpClient.create();

// Singletons: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client =
    S3Client.builder()
        .httpClient(urlHttpClient)
        .defaultsMode(DefaultMode.IN_REGION)
        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
        .build();

DynamoDbClient dynamoDbClient =
    DynamoDbClient.builder()
        .httpClient(urlHttpClient)
        .defaultsMode(DefaultMode.IN_REGION)
        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
        .build();

// Perform work with the s3Client and dynamoDbClient.

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
urlHttpClient.close();
```

Use `UrlConnectionHttpClient` and `ApacheHttpClient` together

When you use the `UrlConnectionHttpClient` in your application, you must supply each service client with either a `UrlConnectionHttpClient` instance or a `ApacheHttpClient` instance using the service client builder's `httpClientBuilder` method.

An exception occurs if your program uses multiple service clients and both of the following are true:

- One service client is configured to use a `URLConnectionHttpClient` instance
- Another service client uses the default `ApacheHttpClient` without explicitly building it with the `httpClient()` or `httpClientBuilder()` methods

The exception will state that multiple HTTP implementations were found on the classpath.

The following example code snippet leads to an exception.

```
// The dynamoDbClient uses the UrlConnectionHttpClient
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(URLConnectionHttpClient.create())
    .build();

// The s3Client below uses the ApacheHttpClient at runtime, without specifying it.
// An SdkClientException is thrown with the message that multiple HTTP implementations
// were found on the classpath.
S3Client s3Client = S3Client.create();

// Perform work with the s3Client and dynamoDbClient.

dynamoDbClient.close();
s3Client.close();
```

Avoid the exception by explicitly configuring the `S3Client` with an `ApacheHttpClient`.

```
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(URLConnectionHttpClient.create())
    .build();

S3Client s3Client = S3Client.builder()
    .httpClient(ApacheHttpClient.create()) // Explicitly build the
    ApacheHttpClient.
    .build();

// Perform work with the s3Client and dynamoDbClient.

dynamoDbClient.close();
s3Client.close();
```

Note

To explicitly create the `ApacheHttpClient`, you must [add a dependency](#) on the `apache-client` artifact in your Maven project file.

Proxy configuration example

The following code snippet uses the [proxy configuration builder for the URL connection HTTP client](#).

```
SdkHttpClient urlHttpClient = UrlConnectionHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://example.com:1234"))
        .username("username")
        .password("password")
        .addNonProxyHost("localhost")
        .addNonProxyHost("host.example.com")
        .build())
    .build();
```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```
$ java -Dhttp.proxyHost=example.com -Dhttp.proxyPort=1234 -Dhttp.proxyUser=username \
-Dhttp.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ...
App
```

The equivalent setup that uses environment variables is:

```
// Set the following environment variables.
// $ export HTTP_PROXY="http://username:password@example.com:1234"
// $ export NO_PROXY="localhost|host.example.com"

// Set the 'useSystemPropertyValues' to false on the proxy configuration.
SdkHttpClient apacheHttpClient = UrlConnectionHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .useSystemPropertyValues(Boolean.FALSE)
        .build())
    .build();
```

```
// Run the application.  
// $ java -cp ... App
```

Note

The `URLConnection`-based HTTP client does not currently support HTTPS proxy system properties or the `HTTPS_PROXY` environment variable.

Configure the Netty-based HTTP client

The default HTTP client for asynchronous operations in the AWS SDK for Java 2.x is the Netty-based [NettyNioAsyncHttpClient](#). The Netty-based client is based on the asynchronous event-driven network framework of the [Netty project](#).

As an alternative HTTP client, you can use the new [AWS CRT-based HTTP client](#). This topic shows you how to configure the `NettyNioAsyncHttpClient`.

Access the NettyNioAsyncHttpClient

In most situations, you use the `NettyNioAsyncHttpClient` without any explicit configuration in asynchronous programs. You declare your asynchronous service clients and the SDK will configure the `NettyNioAsyncHttpClient` with standard values for you.

If you want to explicitly configure the `NettyNioAsyncHttpClient` or use it with multiple service clients, you need to make it available for configuration.

No configuration needed

When you declare a dependency on a service client in Maven, the SDK adds a *runtime* dependency on the `netty-nio-client` artifact. This makes the `NettyNioAsyncHttpClient` class available to your code at runtime, but not at compile time. If you are not configuring the Netty-based HTTP client, you don't need to specify a dependency for it.

In the following XML snippet of a Maven `pom.xml` file, the dependency declared with `<artifactId>dynamodb-enhanced</artifactId>` transitively brings in the Netty-based HTTP client. You don't need to declare a dependency specifically for it.

```
<dependencyManagement>  
  <dependencies>
```

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>bom</artifactId>
  <version>2.27.21</version>
  <type>pom</type>
  <scope>import</scope>
</dependency>
</dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb-enhanced</artifactId>
  </dependency>
</dependencies>
```

With these dependencies, you cannot make any HTTP configuration changes, since the `NettyNioAsyncHttpClient` library is only on the runtime classpath.

Configuration needed

To configure the `NettyNioAsyncHttpClient`, you need to add a dependency on the `netty-nio-client` artifact at *compile* time.

Refer to the following example of a Maven `pom.xml` file to configure the `NettyNioAsyncHttpClient`.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.27.21</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb-enhanced</artifactId>
  </dependency>
```

```
    <!-- By adding the netty-nio-client dependency, NettyNioAsyncHttpClient will
be
        added to the compile classpath so you can configure it. -->
    <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>netty-nio-client</artifactId>
    </dependency>
</dependencies>
```

Use and configure the NettyNioAsyncHttpClient

You can configure an instance of `NettyNioAsyncHttpClient` along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the [NettyNioAsyncHttpClient.Builder](#) to configure the properties for the Netty-based HTTP client instance.

Best practice: dedicate a NettyNioAsyncHttpClient instance to a service client

If you need to configure an instance of the `NettyNioAsyncHttpClient`, we recommend that you build a dedicated `NettyNioAsyncHttpClient` instance. You can do so by using the `httpClientBuilder` method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the `NettyNioAsyncHttpClient` instance is not closed down when it's no longer needed.

The following example creates a `DynamoDbAsyncClient` instance that is used by a `DynamoDbEnhancedAsyncClient` instance. The `DynamoDbAsyncClient` instance contains the `NettyNioAsyncHttpClient` instance with `connectionTimeout` and `maxConcurrency` values. The HTTP instance is created using `httpClientBuilder` method of `DynamoDbAsyncClient.Builder`.

Imports

```
import software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedAsyncClient;
import
    software.amazon.awssdk.enhanced.dynamodb.extensions.AutoGeneratedTimestampRecordExtension;
import software.amazon.awssdk.http.nio.netty.NettyNioAsyncHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import java.time.Duration;
```

Code

```
// DynamoDbAsyncClient is the lower-level client used by the enhanced client.
DynamoDbAsyncClient dynamoDbAsyncClient =
    DynamoDbAsyncClient
        .builder()
            .httpClientBuilder(NettyNioAsyncHttpClient.builder()
                .connectionTimeout(Duration.ofMillis(5_000))
                .maxConcurrency(100)
                .tlsNegotiationTimeout(Duration.ofMillis(3_500)))
            .defaultsMode(DefaultsMode.IN_REGION)
            .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
            .build();

// Singleton: Use dynamoDbAsyncClient and enhancedClient for all requests.
DynamoDbEnhancedAsyncClient enhancedClient =
    DynamoDbEnhancedAsyncClient
        .builder()
            .dynamoDbClient(dynamoDbAsyncClient)
            .extensions(AutoGeneratedTimestampRecordExtension.create())
            .build();

// Perform work with the dynamoDbAsyncClient and enhancedClient.

// Requests completed: Close dynamoDbAsyncClient.
dynamoDbAsyncClient.close();
```

Alternative approach: share a NettyNioAsyncHttpClient instance

To help keep resource and memory usage lower for your application, you can configure a `NettyNioAsyncHttpClient` and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

Note

When a `NettyNioAsyncHttpClient` instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures a Netty-based HTTP client that is used by two service clients. The configured `NettyNioAsyncHttpClient` instance is passed to the `httpClient` method of

each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

Imports

```
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
```

Code

```
// Create a NettyNioAsyncHttpClient shared instance.
SdkAsyncHttpClient nettyHttpClient =
    NettyNioAsyncHttpClient.builder().maxConcurrency(100).build();

// Singletons: Use the s3AsyncClient, dbAsyncClient, and enhancedAsyncClient for all
// requests.
S3AsyncClient s3AsyncClient =
    S3AsyncClient.builder()
        .httpClient(nettyHttpClient)
        .build();

DynamoDbAsyncClient dbAsyncClient =
    DynamoDbAsyncClient.builder()
        .httpClient(nettyHttpClient)
        .defaultsMode(DefaultsMode.IN_REGION)

        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
        .build();

DynamoDbEnhancedAsyncClient enhancedAsyncClient =
    DynamoDbEnhancedAsyncClient.builder()
        .dynamoDbClient(dbAsyncClient)

        .extensions(AutoGeneratedTimestampRecordExtension.create())
        .build();

// Perform work with s3AsyncClient, dbAsyncClient, and enhancedAsyncClient.

// Requests completed: Close all service clients.
s3AsyncClient.close();
dbAsyncClient.close();
```

```
nettyHttpClient.close(); // Explicitly close nettyHttpClient.
```

Proxy configuration example

The following code snippet uses the [proxy configuration builder for the Netty HTTP client](#).

```
SdkAsyncHttpClient nettyHttpClient = NettyNioAsyncHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .scheme("https")
        .host("myproxy")
        .port(1234)
        .username("username")
        .password("password")
        .nonProxyHosts(Set.of("localhost", "host.example.com")))
    .build()
    .build();
```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```
$ java -Dhttps.proxyHost=myproxy -Dhttps.proxyPort=1234 -Dhttps.proxyUser=username \
-Dhttps.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ...
App
```

Important

To use any of the HTTPS proxy system properties, the scheme property must be set in code to `https`. If the scheme property is not set in code, the scheme defaults to `HTTP` and the SDK looks only for `http.*` system properties.

The equivalent setup that uses environment variables is:

```
// Set the following environment variables.
// $ export HTTPS_PROXY="https://username:password@myproxy:1234"
// $ export NO_PROXY="localhost|host.example.com"

// Set the 'useSystemPropertyValues' to false on the proxy configuration.
SdkAsyncHttpClient nettyHttpClient = NettyNioAsyncHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
```

```
        .useSystemPropertyValues(Boolean.FALSE)
        .build())
    .build();

// Run the application.
// $ java -cp ... App
```

Configure AWS CRT-based HTTP clients

The AWS CRT-based HTTP clients include the synchronous [AwsCrtHttpClient](#) and asynchronous [AwsCrtAsyncHttpClient](#). The AWS CRT-based HTTP clients provide the following HTTP client benefits:

- Faster SDK startup time
- Smaller memory footprint
- Reduced latency time
- Connection health management
- DNS load balancing

AWS CRT-based components in the SDK

The AWS CRT-based *HTTP* clients, described in this topic, and the AWS CRT-based *S3* client are different components in the SDK.

The synchronous and asynchronous **AWS CRT-based HTTP clients** are implementations SDK HTTP client interfaces and are used for general HTTP communication. They are alternatives to the other synchronous or asynchronous HTTP clients in the SDK with additional benefits.

The **AWS CRT-based S3 client** is an implementation of the [S3AsyncClient](#) interface and is used for working with the Amazon S3 service. It is an alternative to the Java-based implementation of the [S3AsyncClient](#) interface and offers several advantages.

Although both components use libraries from the [AWS Common Runtime](#), the AWS CRT-based HTTP clients do not use the [aws-c-s3 library](#) and do not support the [S3 multipart upload API](#) features. The AWS CRT-based S3 client, by contrast, was purpose-built to support the S3 multipart upload API features.

Access the AWS CRT-based HTTP clients

Before you can use the AWS CRT-based HTTP clients, add the `aws-crt-client` artifact with a minimum version of 2.22.0 to your project's dependencies.

Use one of the following options to set up your Maven `pom.xml` file.

Note

You might choose to use the *Platform-specific jar option* if you need to keep the size of the runtime dependencies smaller, for example if your application runs in an AWS Lambda function.

Uber-jar option

By default, the `aws-crt-client` uses an uber-jar of AWS CRT artifacts that contains binaries for several platforms, including Linux, Windows, and macOS.

```
<project>
  <properties>
    <aws.sdk.java.version>2.29.10*</aws.sdk.java.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.sdk.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-crt-client</artifactId>
    </dependency>
  </dependencies>
</project>
```

*Replace the version shown in red with the version of the Java SDK that you want to use. Find the latest on [Maven Central](#).

Platform-specific jar option

To restrict the Java runtime to platform-specific version of the AWS CRT library, make the following changes to the *Uber-jar option*.

- Add an `exclusions` element to the SDK's `aws-crt-client` artifact. This exclusion prevents the SDK from transitively using the AWS CRT uber-jar.
- Add a `dependency` element for the specific AWS CRT platform version you need. See the **Steps to determine the AWS CRT artifact version** below for how you can determine the correct version.

```
<project>
  <properties>
    <aws.sdk.java.version>2.29.101</aws.sdk.java.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.sdk.java.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-crt-client</artifactId>
      <exclusions>
        <exclusion>
          <groupId>software.amazon.awssdk.crt</groupId>
          <artifactId>aws-crt</artifactId>
        </exclusion>
      </exclusions>
    </dependency>
    <dependency>
      <groupId>software.amazon.awssdk.crt</groupId>
```

```
<artifactId>aws-crt</artifactId>
<version>0.31.32</version>
<classifier>linux-x86_643</classifier>
</dependency>
</dependencies>
```

¹Replace the version shown in red with the version of the Java SDK that you want to use. Find the latest on [Maven Central](#).

²Replace the version of `software.amazon.awssdk.crt:aws-crt` that would be provided by the *Uber-jar option*. See the following **Steps to determine the AWS CRT artifact version**.

³Replace the `classifier` value with one for your platform. Refer to the AWS CRT for Java GitHub page for a [listing of available values](#).

Steps to determine the AWS CRT artifact version

Use the following steps to determine the AWS CRT artifact version that is compatible with the version of the SDK for Java that you are using.

1. Set up your `pom.xml` file as shown in the *Uber-jar option*. This setup allows you to see what version of `software.amazon.awssdk.crt:aws-crt` the SDK brings in by default.
2. At the root of the project (in the same directory as the `pom.xml` file), run the following Maven command:

```
mvn dependency:tree -Dincludes=software.amazon.awssdk.crt:aws-crt
```

Maven might perform other actions, but at the end you should see console output of the `software.amazon.awssdk.crt:aws-crt` dependency that the SDK transitively uses. The following snippet shows sample output based on an SDK version of `2.29.10`:

```
[INFO] org.example:yourProject:jar:1.0-SNAPSHOT
[INFO] \- software.amazon.awssdk:aws-crt-client:jar:2.29.10:compile
[INFO]    \- software.amazon.awssdk.crt:aws-crt:jar:0.31.3:compile
```

3. Use the version that the console shows for the `software.amazon.awssdk.crt:aws-crt` artifact. In this case, add `0.31.3` to your `pom.xml` file.

Use and configure an AWS CRT-based HTTP client

You can configure an AWS CRT-based HTTP client along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use a builder to [configure the properties](#) for the AWS CRT-based HTTP client instance.

Best practice: dedicate an instance to a service client

If you need to configure an instance of an AWS CRT-based HTTP client, we recommend that you dedicate the instance by building it along with the service client. You can do so by using the `httpClientBuilder` method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the AWS CRT-based HTTP client instance is not closed down when it's no longer needed.

The following example creates an S3 service client and configures an AWS CRT-based HTTP client with `connectionTimeout` and `maxConcurrency` values.

Synchronous client

Imports

```
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

Code

```
// Singleton: Use s3Client for all requests.
S3Client s3Client = S3Client.builder()
    .httpClientBuilder(AwsCrtHttpClient
        .builder()
        .connectionTimeout(Duration.ofSeconds(3))
        .maxConcurrency(100))
    .build();

// Perform work with the s3Client.

// Requests completed: Close the s3Client.
s3Client.close();
```

Asynchronous client

Imports

```
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;
```

Code

```
// Singleton: Use s3AsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClientBuilder(AwsCrtAsyncHttpClient
        .builder()
        .connectionTimeout(Duration.ofSeconds(3))
        .maxConcurrency(100))
    .build();

// Perform work with the s3AsyncClient.

// Requests completed: Close the s3AsyncClient.
s3AsyncClient.close();
```

Alternative approach: share an instance

To help keep resource and memory usage lower for your application, you can configure an AWS CRT-based HTTP client and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

Note

When an AWS CRT-based HTTP client instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an AWS CRT-based HTTP client instance with `connectionTimeout` and `maxConcurrency` values. The configured instance is passed to the `httpClient` method of each service client's builder. When the service clients and the HTTP client are no longer needed, they are explicitly closed. The HTTP client is closed last.

Synchronous client

Imports

```
import
    software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

Code

```
// Create an AwsCrtHttpClient shared instance.
SdkHttpClient crtHttpClient = AwsCrtHttpClient.builder()
    .connectionTimeout(Duration.ofSeconds(3))
    .maxConcurrency(100)
    .build();

// Singletons: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client = S3Client.builder()
    .httpClient(crtHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.crea
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(crtHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.crea
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
crtHttpClient.close(); // Explicitly close crtHttpClient.
```

Asynchronous client

Imports

```
import
    software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.async.SdkAsyncHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;
```

Code

```
// Create an AwsCrtAsyncHttpClient shared instance.
SdkAsyncHttpClient crtAsyncHttpClient = AwsCrtAsyncHttpClient.builder()
    .connectionTimeout(Duration.ofSeconds(3))
    .maxConcurrency(100)
    .build();

// Singletons: Use the s3AsyncClient and dynamoDbAsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClient(crtAsyncHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

DynamoDbAsyncClient dynamoDbAsyncClient = DynamoDbAsyncClient.builder()
    .httpClient(crtAsyncHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

// Requests completed: Close all service clients.
s3AsyncClient.close();
dynamoDbAsyncClient.close();
crtAsyncHttpClient.close(); // Explicitly close crtAsyncHttpClient.
```

Set an AWS CRT-based HTTP client as the default

You can setup your Maven build file to have the SDK use an AWS CRT-based HTTP client as the default HTTP client for service clients.

You do this by adding an `exclusions` element with the default HTTP client dependencies to each service client artifact.

In the following `pom.xml` example, the SDK uses an AWS CRT-based HTTP client for S3 services. If the service client in your code is an `S3AsyncClient`, the SDK uses `AwsCrtAsyncHttpClient`. If the service client is an `S3Client`, the SDK uses `AwsCrtHttpClient`. With this setup the default Netty-based asynchronous HTTP client and the default Apache-based synchronous HTTP are not available.

```
<project>
  <properties>
    <aws.sdk.version>VERSION</aws.sdk.version>
  </properties>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>s3</artifactId>
      <version>${aws.sdk.version}</version>
      <exclusions>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>netty-nio-client</artifactId>
        </exclusion>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>apache-client</artifactId>
        </exclusion>
      </exclusions>
    </dependency>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-crt-client</artifactId>
    </dependency>
  </dependencies>
</project>
```

Visit the Maven central repository for the latest [VERSION](#) value.

Note

If multiple service clients are declared in a `pom.xml` file, all require the `exclusions` XML element.

Use a Java system property

To use the AWS CRT-based HTTP clients as the default HTTP for your application, you can set the Java system property `software.amazon.awssdk.http.async.service.impl` to a value of `software.amazon.awssdk.http.crt.AwsCrtSdkHttpClient`.

To set during application startup, run a command similar to the following.

```
java app.jar -Dsoftware.amazon.awssdk.http.async.service.impl=\
software.amazon.awssdk.http.crt.AwsCrtSdkHttpClient
```

Use the following code snippet to set the system property in your application code.

```
System.setProperty("software.amazon.awssdk.http.async.service.impl",
"software.amazon.awssdk.http.crt.AwsCrtSdkHttpClient");
```

Note

You need to add a dependency on the `aws-crt-client` artifact in your `pom.xml` file when you use a system property to configure the use of the AWS CRT-based HTTP clients.

Advanced configuration of AWS CRT-based HTTP clients

You can use various configuration settings of the AWS CRT-based HTTP clients, including connection health configuration and maximum idle time. You can review the [configuration options available](#) for the `AwsCrtAsyncHttpClient`. You can configure the same options for the `AwsCrtHttpClient`.

Connection health configuration

You can configure connection health configuration for the AWS CRT-based HTTP clients by using the `connectionHealthConfiguration` method on the HTTP client builder.

The following example creates an S3 service client that uses a AWS CRT-based HTTP client instance configured with connection health configuration and a maximum idle time for connections.

Synchronous client

Imports

```
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

Code

```
// Singleton: Use the s3Client for all requests.
S3Client s3Client = S3Client.builder()
    .httpClientBuilder(AwsCrtHttpClient
        .builder()
        .connectionHealthConfiguration(builder -> builder
            .minimumThroughputInBps(32000L)
            .minimumThroughputTimeout(Duration.ofSeconds(3)))
        .connectionMaxIdleTime(Duration.ofSeconds(5)))
    .build();

// Perform work with s3Client.

// Requests complete: Close the service client.
s3Client.close();
```

Asynchronous client

Imports

```
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;
```

Code

```
// Singleton: Use the s3AsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClientBuilder(AwsCrtAsyncHttpClient
```

```
.builder()
    .connectionHealthConfiguration(builder -> builder
        .minimumThroughputInBps(32000L)
        .minimumThroughputTimeout(Duration.ofSeconds(3)))
    .connectionMaxIdleTime(Duration.ofSeconds(5)))
    .build();

// Perform work with s3AsyncClient.

// Requests complete: Close the service client.
s3AsyncClient.close();
```

HTTP/2 support

The HTTP/2 protocol is not yet supported in the AWS CRT-based HTTP clients, but is planned for a future release.

In the meantime, if you are using service clients that require HTTP/2 support such as the [KinesisAsyncClient](#) or the [TranscribeStreamingAsyncClient](#), consider using the [NettyNioAsyncHttpClient](#) instead.

Proxy configuration example

The following code snippet shows the use of the [ProxyConfiguration.Builder](#) that you use to configure proxy setting in code.

Synchronous client

Imports

```
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.http.crt.ProxyConfiguration;
```

Code

```
SdkHttpClient crtHttpClient = AwsCrtHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .scheme("https")
        .host("myproxy")
        .port(1234)
```

```

        .username("username")
        .password("password")
        .nonProxyHosts(Set.of("localhost", "host.example.com"))
        .build()
    .build();

```

Asynchronous client

Imports

```

import software.amazon.awssdk.http.async.SdkAsyncHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.http.crt.ProxyConfiguration;

```

Code

```

SdkAsyncHttpClient crtAsyncHttpClient = AwsCrtAsyncHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .scheme("https")
        .host("myproxy")
        .port(1234)
        .username("username")
        .password("password")
        .nonProxyHosts(Set.of("localhost", "host.example.com"))
        .build())
    .build();

```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```

$ java -Dhttps.proxyHost=myproxy -Dhttps.proxyPort=1234 -Dhttps.proxyUser=username \
-Dhttps.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ...
App

```

Important

To use any of the HTTPS proxy system properties, the scheme property must be set in code to `https`. If the scheme property is not set in code, the scheme defaults to `HTTP` and the SDK looks only for `http.*` system properties.

The equivalent setup that uses environment variables is:

```
// Set the following environment variables.
// $ export HTTPS_PROXY="https://username:password@myproxy:1234"
// $ export NO_PROXY="localhost|host.example.com"

// Set the 'useSystemPropertyValues' to false on the proxy configuration.
SdkAsyncHttpClient crtAsyncHttpClient = AwsCrtAsyncHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .scheme("https")
        .useSystemPropertyValues(Boolean.FALSE)
        .build())
    .build();

// Run the application.
// $ java -cp ... App
```

Configure HTTP proxies

You can configure HTTP proxies by using code, by setting Java system properties, or by setting environment variables.

Configure in code

You configure proxies in code with a client-specific `ProxyConfiguration` builder when you build the service client. The following code shows an example proxy configuration for an Apache-based HTTP client that is used by an Amazon S3 service client.

```
SdkHttpClient httpClient1 = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://proxy.example.com"))
        .username("username")
        .password("password")
        .addNonProxyHost("localhost")
        .build())
    .build();

S3Client s3Client = S3Client.builder()
    .httpClient(httpClient)
    .build();
```

The section for each HTTP client in this topic shows a proxy configuration example.

- [Apache HTTP client](#)
- [URLConnection-based HTTP client](#)
- [Netty-based HTTP client](#)
- [AWS CRT-based HTTP client](#)

Configure HTTP proxies with external settings

Even if you don't explicitly use a `ProxyConfiguration` builder in code, the SDK looks for external settings to configure a default proxy configuration.

By default, the SDK first searches for JVM system properties. If even one property is found, the SDK uses the value and any other system property values. If no system properties are available, the SDK looks for proxy environment variables.

The SDK can use the following Java system properties and environment variables.

Java system properties

System property	Description	HTTP client support
<code>http.proxyHost</code>	Host name of the HTTP proxy server	All
<code>http.proxyPort</code>	Port number of the HTTP proxy server	All
<code>http.proxyUser</code>	Username for HTTP proxy authentication	All
<code>http.proxyPassword</code>	Password for HTTP proxy authentication	All
<code>http.nonProxyHosts</code>	List of hosts that should be reached directly, bypassing the proxy. This list is also valid when HTTPS is used.	All
<code>https.proxyHost</code>	Host name of the HTTPS proxy server	Netty, CRT

System property	Description	HTTP client support
https.proxyPort	Port number of the HTTPS proxy server	Netty, CRT
https.proxyUser	Username for HTTPS proxy authentication	Netty, CRT
https.proxyPassword	Password for HTTPS proxy authentication	Netty, CRT

Environment variables

Environment variable	Description	HTTP client support
HTTP_PROXY ¹	A valid URL with a scheme of HTTP	All
HTTPS_PROXY ¹	A valid URL with a scheme of HTTPS	Netty, CRT
NO_PROXY ²	List of hosts that should be reached directly, bypassing the proxy. The list is valid for both HTTP and HTTPS.	All

View key and footnotes

All - All HTTP clients offered by the SDK—`URLConnectionHttpClient`, `ApacheHttpClient`, `NettyNioAsyncHttpClient`, `AwsCrtAsyncHttpClient`.

Netty - The Netty-based HTTP client (`NettyNioAsyncHttpClient`).

CRT - The AWS CRT-based HTTP clients, (`AwsCrtHttpClient` and `AwsCrtAsyncHttpClient`).

¹The environment variable queried, whether `HTTP_PROXY` or `HTTPS_PROXY`, depends on the scheme setting in the client's `ProxyConfiguration`. The default scheme is HTTP. The following snippet shows how to change the scheme to HTTPS used for environment variable resolution.

```
SdkHttpClient httpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .scheme("https")
        .build())
    .build();
```

²The NO_PROXY environment variable supports a mix of "|" and ";" separators between host names. Host names may include the "*" wildcard.

Use a combination of settings

You can use a combination of HTTP proxy settings in code, system properties, and environment variables.

Example – configuration provided by a system property and by code

```
// Command line with the proxy password set as a system property.
$ java -Dhttp.proxyPassword=SYS_PROP_password -cp ... App

// Since the 'useSystemPropertyValues' setting is 'true' (the default), the SDK will
// supplement
// the proxy configuration in code with the 'http.proxyPassword' value from the system
// property.
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://localhost:1234"))
        .username("username")
        .build())
    .build();

// Use the apache HTTP client with proxy configuration.
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(apacheHttpClient)
    .build();
```

The SDK resolves the following proxy settings.

```
Host = localhost
Port = 1234
Password = SYS_PROP_password
UserName = username
Non ProxyHost = null
```

Example – both system properties and environment variables are available

Each HTTP client's `ProxyConfiguration` builder offers settings named `useSystemPropertyValues` and `useEnvironmentVariablesValues`. By default, both settings are `true`. When `true`, the SDK automatically uses values from system properties or environment variables for options that are not provided by the `ProxyConfiguration` builder.

Important

System properties take precedence over environment variables. If an HTTP proxy system property is found, the SDK retrieves *all* values from system properties and none from environment variables. If you want to prioritize environment variables over system properties, set `useSystemPropertyValues` to `false`.

For this example, the following settings are available at runtime:

```
// System properties
http.proxyHost=SYS_PROP_HOST.com
http.proxyPort=2222
http.password=SYS_PROP_PASSWORD
http.user=SYS_PROP_USER

// Environment variables
HTTP_PROXY="http://EnvironmentUser:EnvironmentPassword@ENV_VAR_HOST:3333"
NO_PROXY="environmentnonproxy.host,environmentnonproxy2.host:1234"
```

The service client is created with one of the following statements. None of the statements explicitly set a proxy setting.

```
DynamoDbClient client = DynamoDbClient.create();
DynamoDbClient client = DynamoDbClient.builder().build();
DynamoDbClient client = DynamoDbClient.builder()
    .httpClient(ApacheHttpClient.builder()
        .proxyConfiguration(ProxyConfiguration.builder()
            .build())
        .build())
    .build();
```

The following proxy settings are resolved by the SDK:

```
Host = SYS_PROP_HOST.com
Port = 2222
Password = SYS_PROP_PASSWORD
UserName = SYS_PROP_USER
Non ProxyHost = null
```

Because the service client has default proxy settings, the SDK searches for system properties and then environment variables. Since system properties settings take precedence over environment variables, the SDK uses only system properties.

If the use of system properties is changed to `false` as shown in the following code, the SDK resolves only the environment variables.

```
DynamoDbClient client = DynamoDbClient.builder()
    .httpClient(ApacheHttpClient.builder()
        .proxyConfiguration(ProxyConfiguration.builder()
            .useSystemPropertyValues(Boolean.FALSE)
            .build())
        .build())
    .build();
```

The resolved proxy settings using HTTP are:

```
Host = ENV_VAR_HOST
Port = 3333
Password = EnvironmentPassword
UserName = EnvironmentUser
Non ProxyHost = environmentnonproxy.host, environmentnonproxy2.host:1234
```

Exception handling for the AWS SDK for Java 2.x

Understanding how and when the AWS SDK for Java 2.x throws exceptions is important to building high-quality applications using the SDK. The following sections describe the different cases of exceptions that are thrown by the SDK and how to handle them appropriately.

Why unchecked exceptions?

The AWS SDK for Java uses runtime (or unchecked) exceptions instead of checked exceptions for these reasons:

- To allow developers fine-grained control over the errors they want to handle without forcing them to handle exceptional cases they aren't concerned about (and making their code overly verbose)
- To prevent scalability issues inherent with checked exceptions in large applications

In general, checked exceptions work well on small scales, but can become troublesome as applications grow and become more complex.

AwsServiceException (and subclasses)

[AwsServiceException](#) is the most common exception that you'll experience when using the AWS SDK for Java. `AwsServiceException` is a subclass of the more general [SdkServiceException](#). `AwsServiceExceptions` represent an error response from an AWS service. For example, if you try to terminate an Amazon EC2 instance that doesn't exist, Amazon EC2 will return an error response and all the details of that error response will be included in the `AwsServiceException` that's thrown.

When you encounter an `AwsServiceException`, you know that your request was successfully sent to the AWS service but couldn't be successfully processed. This can be because of errors in the request's parameters or because of issues on the service side.

`AwsServiceException` provides you with information such as:

- Returned HTTP status code
- Returned AWS error code
- Detailed error message from the service in the [AwsErrorDetails](#) class
- AWS request ID for the failed request

In most cases, a service-specific subclass of `AwsServiceException` is thrown to allow developers fine-grained control over handling error cases through catch blocks. The Java SDK API reference for [AwsServiceException](#) displays the large number of `AwsServiceException` subclasses. Use the subclass links to drill down to see the granular exceptions thrown by a service.

For example, the following links to the SDK API reference show the exception hierarchies for a few common AWS services. The list of subclasses shown on each pages shows the specific exceptions that your code can catch.

- [Amazon S3](#)

- [DynamoDB](#)
- [Amazon SQS](#)

To learn more about an exception, inspect the `errorCode` on the [AwsErrorDetails](#) object. You can use the `errorCode` value to look up information in the service guide API. For example if an `S3Exception` is caught and the `AwsErrorDetails#errorCode()` value is `InvalidRequest`, use the [list of error codes](#) in the Amazon S3 API Reference to see more details.

SdkClientException

[SdkClientException](#) indicates that a problem occurred inside the Java client code, either while trying to send a request to AWS or while trying to parse a response from AWS. An `SdkClientException` is generally more severe than an `SdkServiceException`, and indicates a major problem that is preventing the client from making service calls to AWS services. For example, the AWS SDK for Java throws an `SdkClientException` if no network connection is available when you try to call an operation on one of the clients.

Exceptions and retry behavior

The SDK for Java retries requests for several [client-side exceptions](#) and for [HTTP status codes](#) that it receives from AWS service responses. These errors are handled as part of the legacy `RetryMode` that service clients use by default. The Java API reference for [RetryMode](#) describes the various ways that you can configure the mode.

To customize the exceptions and HTTP status codes that trigger automatic retries, configure your service client with a [RetryPolicy](#) that adds [RetryOnExceptionsCondition](#) and [RetryOnStatusCodeCondition](#) instances.

Retries

Calls to AWS services can fail occasionally for unexpected reasons. Certain errors, such as throttling (rate exceeded) or transient errors, might succeed if the call is retried. The AWS SDK for Java 2.x has a built-in mechanism to detect such errors and automatically retry the call that is enabled by default for all clients.

This page describes how this works, how to configure the distinct modes, and tailor the retry behavior.

Retry strategies

A retry strategy is a mechanism used in the SDK to implement retries. Each SDK client has a retry strategy created at build time that cannot be modified after the client is built.

The retry strategy has the following responsibilities.

- Classify exceptions as retryable or not.
- Compute the suggested delay to wait before the next attempt.
- Maintain a [token bucket](#) that provides a mechanism to stop retries when a large percentage of requests are failing and retries are unsuccessful.

Note

Before the release of *retry strategies* with version 2.26.0 of the SDK, *retry policies* provided the retry mechanism in the SDK. The *retry policy* API is made up of the core [RetryPolicy](#) class in the `software.amazon.awssdk.core.retry` package, whereas the [software.amazon.awssdk.retries](#) package contains the *retry strategy* API elements.

The retry strategy API was introduced as part of the AWS-wide effort to unify the interfaces and behavior of the core components of the SDKs.

The SDK for Java 2.x has three built-in retry strategies: standard, legacy, and adaptive. All three retry strategies are preconfigured to retry on a set of retryable exceptions. Examples of retryable errors are socket timeouts, service-side throttling, concurrency or optimistic lock failures, and transient service errors.

Standard retry strategy

The [standard retry strategy](#) is the recommended `RetryStrategy` implementation for normal use cases. Unlike the `AdaptiveRetryStrategy`, the standard strategy is generally useful across all retry use cases.

By default, the standard retry strategy does the following.

- Retries on the conditions that are configured at build time. You can adjust this with [StandardRetryStrategy.Builder#retryOnException](#).

- Retries 2 times for a total of 3 attempts. You can adjust this with `StandardRetryStrategy.Builder#maxAttempts(int)`.
- For non-throttling exceptions, it uses the [BackoffStrategy#exponentialDelay](#) backoff strategy, with a base delay of 100 milliseconds and a max delay of 20 seconds. You can adjust this with `StandardRetryStrategy.Builder#backoffStrategy`.
- For throttling exceptions, it uses the `BackoffStrategy#exponentialDelay` backoff strategy, with a base delay of 1 second and a max delay of 20 seconds. You can adjust this with `StandardRetryStrategy.Builder#throttlingBackoffStrategy`.
- Performs circuit breaking (disabling retries) in the event of high downstream failures. The first attempt is always executed, only retries are disabled. Adjust with `StandardRetryStrategy.Builder#circuitBreakerEnabled`.

Legacy retry strategy

The [legacy retry strategy](#) is a `RetryStrategy` for normal use cases, however, it is deprecated in favor of the `StandardRetryStrategy`. This is the default retry strategy used by clients when you don't specify another strategy.

It is characterized by treating throttling and non-throttling exceptions differently, for throttling exceptions the base delay for the backoff is larger (500ms) than the base delay for non-throttling exceptions (100ms), and throttling exceptions do not affect the token bucket state.

Experience using this strategy at scale inside AWS has shown that is not particularly better than the standard retry strategy. Moreover, it fails to protect downstream services from retry storms and can lead to resource starvation on the client side.

By default, the legacy retry strategy does the following.

- Retries on the conditions that are configured at build time. You can adjust this with [LegacyRetryStrategy.Builder#retryOnException](#).
- Retries 3 times for a total of 4 attempts. You can adjust this with `LegacyRetryStrategy.Builder#maxAttempts(int)`.
- For non-throttling exceptions, it uses the `BackoffStrategy#exponentialDelay` backoff strategy, with a base delay of 100 milliseconds and a max delay of 20 seconds. You can adjust this with `LegacyRetryStrategy.Builder#backoffStrategy`.

- For throttling exceptions, it uses the `BackoffStrategy#exponentialDelay` backoff strategy, with a base delay of 500 milliseconds and a max delay of 20 seconds. You can adjust this with `LegacyRetryStrategy.Builder#throttlingBackoffStrategy`.
- Performs circuit breaking (disabling retries) in the event of high downstream failures. Circuit breaking never prevents a successful first attempt. You can adjust this behavior with `LegacyRetryStrategy.Builder#circuitBreakerEnabled`.
- The state of the circuit breaker is not affected by throttling exceptions.

Adaptive retry strategy

The [adaptive retry strategy](#) is a `RetryStrategy` for use cases with a high level of resource constraints.

The adaptive retry strategy includes all the features of the standard strategy and adds a client-side rate limiter that measures the rate of throttled requests compared to non-throttled requests. The strategy uses this measurement to slow down the requests in an attempt to stay within a safe bandwidth, ideally causing zero throttling errors.

By default, the adaptive retry strategy does the following.

- Retries on the conditions that are configured at build time. You can adjust this with [AdaptiveRetryStrategy.Builder#retryOnException](#).
- Retries 2 times for a total of 3 attempts. You can adjust this with `AdaptiveRetryStrategy.Builder#maxAttempts(int)`.
- Uses a dynamic backoff delay that is based on the current load against the downstream resource.
- Performs circuit breaking (disabling retries) when there are high number of downstream failures. Circuit breaking may prevent a second attempt in outage scenarios to protect the downstream service.

Warning

The adaptive retry strategy assumes that the client works against a single resource (for example, one DynamoDB table or one Amazon S3 bucket).

If you use a single client for multiple resources, throttling or outages associated with one resource result in increased latency and failures when the client accesses all other

resources. When you use the adaptive retry strategy, we recommend that you use a single client for each resource.

We also recommend that you use this strategy in situations where all clients use the adaptive retry strategy against the resource.

Important

The release of retry strategies with 2.26.0 of the Java SDK includes the new [RetryMode.ADAPTIVE_V2](#) enumeration value. The ADAPTIVE_V2 mode corrects an error that failed to delay the first attempt when throttling errors were detected previously. With the 2.26.0 release, users automatically get the ADAPTIVE_V2 mode behavior by setting the mode as adaptive with an environment variable, system property, or profile setting. There is no adaptive_v2 value for these settings. See the following [the section called “Specify a strategy”](#) section for how to set the mode.

Users can get the previous behavior by setting the mode in code using `RetryMode.ADAPTIVE`.

Summary: Comparison of retry strategy default values

The following table shows the default values for the properties of each retry strategy.

Strategy	Maximum attempts	Base delay for non-throttling errors	Base delay for throttling errors	Token bucket size	Token cost per non-throttling retry	Token cost per throttling retry
Standard	3	100 ms	1000 ms	500	5	5
Legacy	4	100 ms	500 ms	500	5	0
Adaptive	3	100 ms	100 ms	500	5	5

Specify a strategy

You have four ways to specify a strategy for your service client.

In code

When you build a client, you can configure a lambda expression with a retry strategy. The following snippet configures a standard retry strategy that uses default values on a DynamoDB service client.

```
DynamoDbClient client = DynamoDbClient.builder()
    .overrideConfiguration(o -> o.retryStrategy(RetryMode.STANDARD))
    .build();
```

You can specify `RetryMode.LEGACY` or `RetryMode.ADAPTIVE` in place of `RetryMode.STANDARD`.

As a profile setting

Include `retry_mode` as profile setting in the [shared AWS config file](#). Specify `standard`, `legacy`, or `adaptive` as a value. When set as a profile setting, all service clients that are created while the profile is active use the specified retry strategy with default values. You can override this setting by configuring a retry strategy in code as shown previously.

With the following profile, all service clients use the standard retry strategy.

```
[profile dev]
region = us-east-2
retry_mode = standard
```

As a JVM system property

You can configure a retry strategy for all service clients, unless overridden in code, by using the system property `aws.retryMode`. Specify `standard`, `legacy`, or `adaptive` as a value.

Use the `-D` switch when you invoke Java as shown in the following command.

```
java -Daws.retryMode=standard ...
```

Alternatively, set the system property in the code *before* creating any client as shown in the following snippet.

```
public void main(String[] args) {
    // Set the property BEFORE any AWS service clients are created.
    System.setProperty("aws.retryMode", "standard");
}
```

```
    ...  
}
```

With an environment variable

You can also use the `AWS_RETRY_MODE` environment variable with a value of `standard`, `legacy`, or `adaptive`. As with a profile setting or JVM system property, the environment variable configures all service clients with the specified retry mode unless you configure a client in code.

The following command sets the retry mode to `standard` for the current shell session.

```
export AWS_RETRY_MODE=standard
```

Customize a strategy

You can customize any retry strategy by setting the maximum attempts, backoff strategy, and exceptions that are retryable. You can customize when you build a retry strategy or when you build a client by using an override builder that allows further refinements of the configured strategy.

Customize maximum attempts

You can configure the maximum number of attempts during client construction as shown in the following statement. The following statement customizes the default retry strategy for the client to a maximum of 5 attempt--a first attempt plus 4 retries.

```
DynamoDbClient client = DynamoDbClient.builder()  
    .overrideConfiguration(o -> o.retryStrategy(b -> b.maxAttempts(5)))  
    .build();
```

Alternatively, you can build the strategy and provide it to the client as in the following code example. The following code replaces the standard 3 maximum attempts with 10 and configures a DynamoDB client with the customized strategy.

```
StandardRetryStrategy strategy = AwsRetryStrategy.standardRetryStrategy()  
    .toBuilder()  
    .maxAttempts(10)  
    .build();  
DynamoDbClient client = DynamoDbClient.builder()  
    .overrideConfiguration(o -> o.retryStrategy(strategy))  
    .build();
```

⚠ Warning

We recommended that you configure each client with a unique `RetryStrategy` instance. If a `RetryStrategy` instance is shared, failures in one client might affect the retry behavior in the other.

You can also set the maximum number of attempts for all clients by using [external settings](#) instead of code. You configure this setting as describe in the [the section called “Specify a strategy”](#) section.

Customize retryable exceptions

You can configure additional exceptions that trigger retries during client construction. This customization is provided for edge cases where exceptions are thrown that are not included in the default set of retryable exceptions.

The following code snippet shows the methods you use to customize the retry exceptions--`retryOnException` and `retryOnExceptionOrCause`. The `retryOnExceptionOrCause` methods adds a retryable exception if the SDK throws the direct exception or if the exception is wrapped.

```
DynamoDbClient client = DynamoDbClient.builder()
    .overrideConfiguration(o -> o.retryStrategy(
        b -> b.retryOnException(EdgeCaseException.class)
            .retryOnExceptionOrCause(WrappedEdgeCaseException.class)))
    .build();
```

Customize the backoff strategy

You can build the backoff strategy and supply it to the client.

The following code builds a `BackoffStrategy` that replaces the default, standard strategy's exponential delay backoff strategy.

```
BackoffStrategy backoffStrategy =
    BackoffStrategy.exponentialDelay(Duration.ofMillis(150), // The base delay.
                                    Duration.ofSeconds(15)); // The maximum delay.
DynamoDbClient client = DynamoDbClient.builder()
    .overrideConfiguration(o -> o.retryStrategy(
        b -> b.backoffStrategy(backoffStrategy)))
```

```
.build();
```

Migrating from `RetryPolicy` to `RetryStrategy`

`RetryPolicy` (the retry policy API) will be supported for the foreseeable future. If you currently use an instance of `RetryPolicy` to configure your client, everything is going to work as before. Behind the scenes the Java SDK adapts it to a `RetryStrategy`. The new retry strategy interfaces provide the same functionality as a `RetryPolicy` but are created and configured differently.

Implement `ContentStreamProvider` in the AWS SDK for Java 2.x

`ContentStreamProvider` is an abstraction used in the AWS SDK for Java 2.x to allow multiple reads of input data. This topic explains how to implement a `ContentStreamProvider` correctly for your applications.

The SDK for Java 2.x uses the `ContentStreamProvider#newStream()` method each time it needs to read an entire stream. For this to work for the entire stream, the returned stream must always be at the start of the content and it must contain the same data.

In the following sections, we provide three approaches for how to implement this behavior correctly.

Use `mark()` and `reset()`

In the example below, we use `mark(int)` in the constructor before reading begins to ensure that we can reset the stream back to the beginning. For each invocation of `newStream()` we reset the stream:

```
public class MyContentStreamProvider implements ContentStreamProvider {
    private InputStream contentStream;

    public MyContentStreamProvider(InputStream contentStream) {
        this.contentStream = contentStream;
        this.contentStream.mark(MAX_LEN);
    }

    @Override
```

```
public InputStream newStream() {
    contentStream.reset();
    return contentStream;
}
}
```

Use buffering if `mark()` and `reset()` are not available

If your stream doesn't support `mark()` and `reset()` directly, you can still use the solution shown previously by first wrapping the stream in a `BufferedInputStream`:

```
public class MyContentStreamProvider implements ContentStreamProvider {
    private BufferedReader contentStream;

    public MyContentStreamProvider(InputStream contentStream) {
        this.contentStream = new BufferedInputStream(contentStream);
        this.contentStream.mark(MAX_LEN);
    }

    @Override
    public InputStream newStream() {
        contentStream.reset();
        return contentStream;
    }
}
```

Create new streams

A simpler approach is to simply obtain a new stream to your data on each invocation and close the previous one:

```
public class MyContentStreamProvider implements ContentStreamProvider {
    private InputStream contentStream;

    @Override
    public InputStream newStream() {
        if (contentStream != null) {
            contentStream.close();
        }
        contentStream = openStream();
        return contentStream;
    }
}
```

```
}
```

Logging with the SDK for Java 2.x

The AWS SDK for Java 2.x uses [SLF4J](#), which is an abstraction layer that enables the use of any one of several logging systems at runtime.

Supported logging systems include the Java Logging Framework and Apache [Log4j 2](#), among others. This topic shows you how to use Log4j 2 as the logging system for working with the SDK.

Log4j 2 configuration file

You typically use a configuration file, named `log4j2.xml` with Log4j 2. Example configuration files are shown below. To learn more about the values used in the configuration file, see the [manual for Log4j configuration](#).

The `log4j2.xml` file needs to be on the classpath when your application starts up. For a Maven project, put the file in the `<project-dir>/src/main/resources` directory.

The `log4j2.xml` configuration file specifies properties such as [logging level](#), where logging output is sent (for example, [to a file or to the console](#)), and the [format of the output](#). The logging level specifies the level of detail that Log4j 2 outputs. Log4j 2 supports the concept of multiple logging [hierarchies](#). The logging level is set independently for each hierarchy. The main logging hierarchy that you use with the AWS SDK for Java 2.x is `software.amazon.awssdk`.

Add logging dependency

To configure the Log4j 2 binding for SLF4J in your build file, use the following.

Maven

Add the following elements to your `pom.xml` file.

```
...
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-slf4j2-impl</artifactId>
  <version>VERSION</version>
</dependency>
...
```

Gradle–Kotlin DSL

Add the following to your `build.gradle.kts` file.

```
...
dependencies {
    ...
    implementation("org.apache.logging.log4j:log4j-slf4j2-impl:VERSION")
    ...
}
...
```

Use `2.20.0` for the minimum version of the `log4j-slf4j2-impl` artifact. For the latest version, use the version published to [Maven central](#). Replace `VERSION` with version you'll use.

SDK-specific errors and warnings

We recommend that you always leave the `software.amazon.awssdk` logger hierarchy set to `WARN` to catch any important messages from the SDK's client libraries. For example, if the Amazon S3 client detects that your application hasn't properly closed an `InputStream` and could be leaking resources, the S3 client reports it through a warning message to the logs. This also ensures that messages are logged if the client has any problems handling requests or responses.

The following `log4j2.xml` file sets the `rootLogger` to `WARN`, which causes warning and error-level messages from all loggers in the application to be output, *including* those in the `software.amazon.awssdk` hierarchy. Alternatively, you can explicitly set the `software.amazon.awssdk` logger hierarchy to `WARN` if `<Root level="ERROR">` is used.

Example Log4j2.xml configuration file

This configuration will log messages at the `ERROR` and `WARN` levels to the console for all logger hierarchies.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>
```

```
<Loggers>
  <Root level="WARN">
    <AppenderRef ref="ConsoleAppender"/>
  </Root>
</Loggers>
</Configuration>
```

Request/response summary logging

Every request to an AWS service generates a unique AWS request ID that is useful if you run into an issue with how an AWS service is handling a request. AWS request IDs are accessible programmatically through [SdkServiceException](#) objects in the SDK for any failed service call, and can also be reported through the "DEBUG" log level of the "software.amazon.awssdk.request" logger.

The following `log4j2.xml` file enables a summary of requests and responses.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="ERROR">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="WARN" />
    <Logger name="software.amazon.awssdk.request" level="DEBUG" />
  </Loggers>
</Configuration>
```

Here is an example of the log output:

```
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Sending Request:
DefaultSdkHttpFullRequest(httpMethod=POST, protocol=https, host=dynamodb.us-
east-1.amazonaws.com, encodedPath=/, headers=[amz-sdk-invocation-id, Content-Length,
Content-Type, User-Agent, X-Amz-Target], queryParameters=[])
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Received
successful response: 200, Request ID:
```

```
QS9DUMME2NHEDH8TGT9N5V530JV4KQNS05AEMVJF66Q9ASUAAJG, Extended Request ID: not available
```

If you are interested in only the request ID use `<Logger name="software.amazon.awssdk.requestId" level="DEBUG" />`.

Debug-level SDK logging

If you need more detail about what the SDK is doing, you can set the logging level of the `software.amazon.awssdk` logger to `DEBUG`. At this level, the SDK outputs a large amount of detail, so we recommend that you set this level to resolve errors using integration tests.

At this logging level, the SDK logs information about configuration, credentials resolution, execution interceptors, high-level TLS activity, request signing, and much more.

The following is a sampling of statements that are output by the SDK at `DEBUG` level for a `S3Client#listBuckets()` call.

```
DEBUG s.a.a.r.p.AwsRegionProviderChain:57 - Unable to load region from

The following `log4j2.xml` file configures the previous output.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%-5p %c{1.}:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="DEBUG" />
  </Loggers>
</Configuration>
```

Enable wire logging

It can be useful to see the exact requests and responses that the SDK for Java 2.x sends and receives. If you need access to this information, you can temporarily enable it by adding the necessary configuration depending on the HTTP client the service client uses.

By default, synchronous service clients, such as the [S3Client](#), use an underlying Apache HttpClient, and asynchronous service clients, such as the [S3AsyncClient](#), use a Netty non-blocking HTTP client.

Here is a breakdown of HTTP clients you can use for the two categories of service clients:

Synchronous HTTP Clients	Asynchronous HTTP Clients
ApacheHttpClient (default)	NettyNioAsyncHttpClient (default)
URLConnectionHttpClient	AwsCrtAsyncHttpClient
AwsCrtHttpClient	

Consult the appropriate tab below for configuration settings you need to add depending on the underlying HTTP client.

Warning

We recommend you only use wire logging for debugging purposes. Disable it in your production environments because it can log sensitive data. It logs the full request or response without encryption, even for an HTTPS call. For large requests (e.g., to upload a file to Amazon S3) or responses, verbose wire logging can also significantly impact your application's performance.

ApacheHttpClient

Add the "org.apache.http.wire" logger to the `log4j2.xml` configuration file and set the level to "DEBUG".

The following `log4j2.xml` file turns on full wire logging for the Apache HttpClient.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="WARN" />
    <Logger name="software.amazon.awssdk.request" level="DEBUG" />
    <Logger name="org.apache.http.wire" level="DEBUG" />
  </Loggers>
</Configuration>
```

An additional Maven dependency on the `log4j-1.2-api` artifact is required for wire logging with Apache since it uses 1.2 under the hood.

The full set of Maven dependencies for log4j 2, including wire logging for the Apache HTTP client are shown in the following build file snippets.

Maven

```

...
<dependencyManagement>
  ...
  <dependencies>
    <dependency>
      <groupId>org.apache.logging.log4j</groupId>
      <artifactId>log4j-bom</artifactId>
      <version>VERSION</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
...
<!-- The following is needed for Log4j2 with SLF4J -->
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-slf4j2-impl</artifactId>
</dependency>

<!-- The following is needed for Apache HttpClient wire logging -->
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-1.2-api</artifactId>
</dependency>
...

```

Gradle–Kotlin DSL

```

...
dependencies {
  ...
  implementation(platform("org.apache.logging.log4j:log4j-bom:VERSION"))
  implementation("org.apache.logging.log4j:log4j-slf4j2-impl")
  implementation("org.apache.logging.log4j:log4j-1.2-api")
}
...

```

Use 2.20.0 for the minimum version of the log4j-bom artifact. For the latest version, use the version published to [Maven central](#). Replace *VERSION* with version you'll use.

URLConnectionHttpClient

To log details for service clients that use the `URLConnectionHttpClient`, first create a `logging.properties` file with the following contents:

```
handlers=java.util.logging.ConsoleHandler
java.util.logging.ConsoleHandler.level=FINEST
sun.net.www.protocol.http.HttpURLConnection.level=ALL
```

Set the following JVM system property with the full path of the `logging.properties`:

```
-Djava.util.logging.config.file=/full/path/to/logging.properties
```

This configuration will log the only the headers of the request and response, for example:

```
<Request> FINE: sun.net.www.MessageHeader@35a9782c11 pairs: {GET /fileuploadtest
HTTP/1.1: null}{amz-sdk-invocation-id: 5f7e707e-4ac5-bef5-ba62-00d71034ffdc}
{amz-sdk-request: attempt=1; max=4}{Authorization: AWS4-HMAC-SHA256
Credential=<deleted>/20220927/us-east-1/s3/aws4_request, SignedHeaders=amz-sdk-
invocation-id;amz-sdk-request;host;x-amz-content-sha256;x-amz-date;x-amz-te,
Signature=e367fa0bc217a6a65675bb743e1280cf12f8e8d566196a816d948fdf0b42ca1a}{User-
Agent: aws-sdk-java/2.17.230 Mac_OS_X/12.5 OpenJDK_64-Bit_Server_VM/25.332-b08

legacy}{x-amz-content-sha256: UNSIGNED-PAYLOAD}{X-Amz-Date: 20220927T133955Z}{x-amz-
te: append-md5}{Host: tkhill-test1.s3.amazonaws.com}{Accept: text/html, image/gif,
image/jpeg, *; q=.2, */*; q=.2}{Connection: keep-alive}
<Response> FINE: sun.net.www.MessageHeader@70a36a6611 pairs: {null: HTTP/1.1
200 OK}{x-amz-id-2: sAFeZD0KdUMsBbkdjyDZw7P0oocb4C9KbiuzfJ6TWKQsGXHM/
dFu0vr2tUb7Y1wEHGdJ3DSIxq0=}{x-amz-request-id: P9QW9SMZ97FKZ9X7}{Date: Tue,
27 Sep 2022 13:39:57 GMT}{Last-Modified: Tue, 13 Sep 2022 14:38:12 GMT}{ETag:
"2cbe5ad4a064cedec33b452bebf48032"}{x-amz-transfer-encoding: append-md5}{Accept-
Ranges: bytes}{Content-Type: text/plain}{Server: AmazonS3}{Content-Length: 67}
```

To see the request/response bodies, add `-Djavax.net.debug=all` to the JVM properties. This additional property logs a great deal of information, including all SSL information.

Within the log console or log file, search for "GET" or "POST" to quickly go to the section of the log containing actual requests and responses. Search for "Plaintext before ENCRYPTION" for requests and "Plaintext after DECRYPTION" for responses to see the full text of the headers and bodies.

NettyNioAsyncHttpClient

If your asynchronous service client uses the default `NettyNioAsyncHttpClient`, add two additional loggers to your `log4j2.xml` file to log HTTP headers and request/response bodies.

```
<Logger name="io.netty.handler.logging" level="DEBUG" />
<Logger name="io.netty.handler.codec.http2.Http2FrameLogger" level="DEBUG" />
```

Here is a complete `log4j2.xml` example:

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m
%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="WARN" />
    <Logger name="software.amazon.awssdk.request" level="DEBUG" />
    <Logger name="io.netty.handler.logging" level="DEBUG" />
    <Logger name="io.netty.handler.codec.http2.Http2FrameLogger" level="DEBUG" /
  >
  </Loggers>
</Configuration>
```

These settings log all header details and request/response bodies.

AwsCrtAsyncHttpClient/AwsCrtHttpClient

If you have configured your service client to use an instance of an AWS CRT-based HTTP client, you can log details by setting JVM system properties or programmatically.

Log to a file at "Debug" level

Using system properties:

Programmatically:

```
import software.amazon.awssdk.crt.Log;
```

```
-Daws.crt.log.level=Trace
-Daws.crt.log.destination=File
-Daws.crt.log.filename=<path to file>
```

```
// Execute this statement before constructing the
SDK service client.
Log.initLoggingToFile(Log.LogLevel.Trace,
"<path to file>");
```

Log to the console at "Debug" level

Using system properties:

```
-Daws.crt.log.level=Trace
-Daws.crt.log.destination=Stdout
```

Programmatically:

```
import software.amazon.awssdk.crt.Log;

// Execute this statement before constructing the
SDK service client.
Log.initLoggingToStdout(Log.LogLevel.Trace);
```

For security reasons, at the "Trace" level the AWS CRT-based HTTP clients log only response headers. Request headers, request bodies, and response bodies are not logged.

Set the JVM TTL for DNS name lookups

The Java virtual machine (JVM) caches DNS name lookups. When the JVM resolves a hostname to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of 5 seconds. This ensures that when a resource's IP address changes, your application will be able to receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it will *never* refresh DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it won't be able to use that resource until you *manually restart* the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it will periodically refresh its cached IP information.

How to set the JVM TTL

To modify the JVM's TTL, set the [networkaddress.cache.ttl](#) security property value, set the `networkaddress.cache.ttl` property in the `$JAVA_HOME/jre/lib/security/java.security` file for Java 8 or `$JAVA_HOME/conf/security/java.security` file for Java 11 or higher.

The following is a snippet from a `java.security` file that shows the TTL cache set to 5 seconds.

```
#
# This is the "master security properties file".
#
# An alternate java.security properties file may be specified
...
# The Java-level namelookup cache policy for successful lookups:
#
# any negative value: caching forever
# any positive value: the number of seconds to cache an address for
# zero: do not cache
...
networkaddress.cache.ttl=5
...
```

All applications that run on the JVM represented by the `$JAVA_HOME` environment variable use this setting.

Best practices for AWS SDK for Java 2.x

Reuse a service client, if possible

Each [service client](#) maintains its own HTTP connection pool. A connection that already exists in the pool can be reused by a new request to cut down the time to establish a new connection. We recommend sharing a single instance of the client to avoid the overhead of having too many connection pools that aren't used effectively. All service clients are thread safe.

If you don't want to share a client instance, call `close()` on the instance to release the resources when the client is not needed.

Close an service client, if it's no longer needed

Close a [service client](#) to release resources, such as threads, if it is no longer needed. If you don't want to share a client instance, call `close()` on the instance to release the resources when the client is not needed.

Close input streams from client operations

For streaming operations such as [S3Client#getObject](#), if you are working with [ResponseInputStream](#) directly, we recommend that you do the following:

- Read all the data from the input stream as soon as possible.
- Close the input stream as soon as possible.

We make these recommendations because the input stream is a direct stream of data from the HTTP connection and the underlying HTTP connection can't be reused until all data from the stream has been read and the stream is closed. If these rules are not followed, the client can run out of resources by allocating too many open, but unused, HTTP connections.

Tune HTTP configurations based on performance tests

The SDK provides a set of [default http configurations](#) that apply to general use cases. We recommend that customers tune HTTP configurations for their applications based on their use cases.

As a good starting point, the SDK offers a [smart configuration defaults](#) feature. This feature is available starting with version 2.17.102. You choose a mode depending on your use case, which provides sensible configuration values.

Use OpenSSL for the Netty-based HTTP client

By default, the SDK's [NettyNioAsyncHttpClient](#) uses the JDK's default SSL implementation as the `SslProvider`. Our testing found that OpenSSL performs better than JDK's default implementation. The Netty community also [recommends using OpenSSL](#).

To use OpenSSL, add `netty-tcnative` to your dependencies. For configuration details, see the [Netty project documentation](#).

After you have `netty-tcnative` configured for your project, the `NettyNioAsyncHttpClient` instance will automatically select OpenSSL. Alternatively, you can set the `SslProvider` explicitly using the `NettyNioAsyncHttpClient` builder as shown in the following snippet.

```
NettyNioAsyncHttpClient.builder()
    .sslProvider(SslProvider.OPENSSL)
    .build();
```

Configure API timeouts

The SDK provides [default values](#) for some timeout options, such as connection timeout and socket timeouts, but not for API call timeouts or individual API call attempt timeouts. It is a good practice to set timeouts for both the individual attempts and the entire request. This will ensure your application fails fast in an optimal way when there are transient issues that could cause request attempts to take longer to complete or fatal network issues.

You can configure timeouts for all requests made by a service clients using [ClientOverrideConfiguration#apiCallAttemptTimeout](#) and [ClientOverrideConfiguration#apiCallTimeout](#).

The following example shows the configuration of an Amazon S3 client with custom timeout values.

```
S3Client.builder()
    .overrideConfiguration(
        b -> b.apiCallTimeout(Duration.ofSeconds(<custom value>))
            .apiCallAttemptTimeout(Duration.ofMillis(<custom value>)))
    .build();
```

apiCallAttemptTimeout

This setting sets the amount of time for a single HTTP attempt, after which the API call can be retried.

apiCallTimeout

The value for this property configures the amount of time for the entire execution, including all retry attempts.

As an alternative to setting these timeout values on the service client, you can use [RequestOverrideConfiguration#apiCallTimeout\(\)](#) and [RequestOverrideConfiguration#apiCallAttemptTimeout\(\)](#) to configure a single request .

The following example configures a single `listBuckets` request with custom timeout values.

```
s3Client.listBuckets(lbr -> lbr.overrideConfiguration(
    b -> b.apiCallTimeout(Duration.ofSeconds(<custom value>))
        .apiCallAttemptTimeout(Duration.ofMillis(<custom value>))));
```

When you use these properties together, you set a hard limit on the total time spent on all attempts across retries. You also set an individual HTTP request to fail fast on a slow request.

Use metrics

The SDK for Java can [collect metrics](#) for the service clients in your application. You can use these metrics to identify performance issues, review overall usage trends, review service client exceptions returned, or to dig in to understand a particular issue.

We recommend that you collect metrics, then analyze the Amazon CloudWatch Logs, in order to gain a deeper understanding of your application's performance.

Troubleshooting FAQs

As you use the AWS SDK for Java 2.x in your applications, you might encounter the runtime errors listed in this topic. Use the suggestions here to help you uncover the root cause and resolve the error.

How do I fix "java.net.SocketException: Connection reset" or "server failed to complete the response" error?

A connection reset error indicates that your host, the AWS service, or any intermediary party (for example, a NAT gateway, a proxy, a load balancer) closed the connection before the request was complete. Because there are many causes, finding a solution requires that you know why the connection is being closed. The following items commonly cause a connection to be closed.

- **The connection is inactive.** This is common for streaming operations, where data is not being written to or from the wire for a period of time, so an intermediary party detects the connection

as dead and closes it. To prevent this, be sure your application actively downloads or uploads data.

- **You've closed the HTTP or SDK client.** Be sure not to close resources while they are in use.
- **A misconfigured proxy.** Try to bypass any proxies that you've configured to see if it fixes the problem. If this fixes the issue, the proxy is closing your connection for some reason. Research your specific proxy to determine why it's closing the connection.

If you cannot identify the problem, try running a TCP dump for an affected connection at the client edge of your network (for example, after any proxies that you control).

If you see that the AWS endpoint is sending a TCP RST (reset), [contact the affected service](#) to see if they can determine why the reset is occurring. Be prepared to provide request IDs and timestamps of when the issue occurred. The AWS support team might also benefit from [wire logs](#) that show exactly what bytes your application is sending and receiving and when.

How do I fix "connection timeout"?

A connection timeout error indicates that your host, the AWS service, or any intermediary party (for example, a NAT gateway, a proxy, a load balancer) failed to establish a new connection with the server within the configured connection timeout. The following items describe common causes of this issue.

- **The configured connection timeout is too low.** By default, the connection timeout is 2 seconds in the AWS SDK for Java 2.x. If you set the connection timeout too low, you may get this error. The recommended connection timeout is 1 second if you make only in-region calls and 3 seconds if you make cross-region requests.
- **A misconfigured proxy.** Try to bypass any proxies that you configured to see if it fixes the problem. If this fixes the issue, the proxy is the reason for the connection timeout. Research your specific proxy to determine why that is happening

If you cannot identify the problem, try running a TCP dump for an affected connection at the client edge of your network (for example, after any proxies that you control) to investigate any network issue.

How do I fix "java.net.SocketTimeoutException: Read timed out"?

A read timed out error indicates that the JVM attempted to read data from the underlying operating system, but data was not returned within the time configured via the SDK. This error can occur if the operating system, the AWS service, or any intermediary party (for example, a NAT gateway, a proxy, a load balancers) fails to send data within the time expected by the JVM. Because there are many causes, finding a solution requires that you know why the data is not being returned.

Try running a TCP dump for an affected connection at the client edge of your network (for example, after any proxies that you control).

If you see that the AWS endpoint is sending a TCP RST (reset), [contact the affected service](#). Be prepared to provide request IDs and timestamps of when the issue occurred. The AWS support team might also benefit from [wire logs](#) that show exactly what bytes your application is sending and receiving and when.

How do I fix "Unable to execute HTTP request: Timeout waiting for connection from pool" error?

This error indicates that a request cannot get a connection from the pool within the specified maximum time. To troubleshoot the issue, we recommend that you [enable SDK client-side metrics](#) to publish metrics to Amazon CloudWatch. The HTTP metrics can help narrow down the root cause. The following items describe common causes of this error.

- **Connection leak.** You can investigate this by checking `LeasedConcurrency`, `AvailableConcurrency`, and `MaxConcurrency` metrics. If `LeasedConcurrency` increases until it reaches `MaxConcurrency` but never decreases, there may be a connection leak. A common cause of a leak is because a streaming operation—such as a `S3 getObject` method—is not closed. We recommend that your application read all data from the input stream as soon as possible and [close the input stream afterwards](#). The following chart shows what SDK metrics might look like for connection leak.

- **Connection pool starvation.** This can happen if your request rate is too high and the connection pool size that has been configured cannot meet the request demand. The default connection pool size is 50, and when the connections in the pool reach the maximum, the HTTP client queues incoming requests until connections become available. The following chart shows what SDK metrics might look like for connection pool starvation.

To mitigate this issue, consider taking any of the following actions.

- Increase the connection pool size,
- Increase acquire timeout.
- Slow the request rate.

By increasing the maximum number of connections, client throughput can increase (unless the network interface is already fully utilized). However, you can eventually hit operation system limitations on the number of file descriptors used by the process. If you already fully use your network interface or cannot further increase your connection count, try increasing the acquire timeout. With the increase, you gain extra time for requests to acquire a connection before timing out. If the connections don't free up, the subsequent requests will still timeout.

If you are unable to fix the issue by using the first two mechanisms, slow the request rate by trying the following options.

- Smooth out your requests so that large traffic bursts don't overload the client.
- Be more efficient with calls to AWS services.
- Increase the number of hosts sending requests.

- **I/O Threads are too busy.** This only applies if you are using an asynchronous SDK client with [NettyNioAsyncHttpClient](#). If the `AvailableConcurrency` metric is not low—indicating that connections are available in the pool—but `ConcurrencyAcquireDuration` is high, it might be because I/O threads are not able to handle the requests. Be sure you are not passing `Runnable::run` as a [future completion executor](#) and performing time-consuming task in the response future completion chain since this can block an I/O thread. If that is not the case, consider increasing the number of I/O threads by using the [eventLoopGroupBuilder](#) method. For reference, the default number of I/O threads for a `NettyNioAsyncHttpClient` instance is twice the number of CPU cores of the host.
- **High TLS handshake latency.** If your `AvailableConcurrency` metric is near 0 and `LeasedConcurrency` is lower than `MaxConcurrency`, it might be because the TLS handshake latency is high. The following chart shows what SDK metrics might look like for high TLS handshake latency.

For HTTP clients offered by the Java SDK that are not based on CRT, try enabling [TLS logs](#) to troubleshoot TLS issues. For the AWS CRT-based HTTP client, try enabling [AWS CRT logs](#). If you see that the AWS endpoint seems to take a long time to perform a TLS handshake, you should [contact the affected service](#).

How do I fix a `NoClassDefFoundError`, `NoSuchMethodError` or `NoSuchFieldError`?

A `NoClassDefFoundError` indicates that a class could not be loaded at runtime. The two most common causes for this error are:

- the class does not exist in the classpath because the JAR is missing or the wrong version of the JAR is on the classpath.
- the class failed to load because its static initializer threw an exception.

Similarly, `NoSuchMethodErrors` and `NoSuchFieldErrors` typically result from a mismatched JAR version. We recommend that you perform the following steps.

1. **Check your dependencies** to make sure that you're using the *same version of all SDK jars*. The most common reason that a class, method, or field cannot be found is when you upgrade to a new client version but you continue to use an old 'shared' SDK dependency version. The new client version might attempt to use classes that exist only in newer 'shared' SDK dependencies. Try running `mvn dependency:tree` or `gradle dependencies` (for Gradle) to verify that the SDK library versions all match. To avoid this issue completely in the future, we recommend using [BOM \(Bill of Materials\)](#) to manage SDK module versions.

The following example shows you an example of mixed SDK versions.

```
[INFO] +- software.amazon.awssdk:dynamodb:jar:2.20.00:compile
[INFO] | +- software.amazon.awssdk:aws-core:jar:2.13.19:compile
[INFO] +- software.amazon.awssdk:netty-nio-client:jar:2.20.00:compile
```

The version of `dynamodb` is 2.20.00 and the version of `aws-core` is 2.13.19. The `aws-core` artifact version should also be 2.20.00.

2. **Check statements early in your logs** to see if a class is failing to load because of a static initialization failure. The first time the class fails to load, it may throw a different, more useful exception that specifies *why* the class cannot be loaded. This potentially useful exception occurs only once, so later log statements will only report that the class is not found.
3. **Check your deployment process** to make sure that it actually deploys required JAR files along with your application. It's possible that you're building with the correct version, but the process that creates the classpath for your application is excluding a required dependency.

How do I fix a "SignatureDoesNotMatch" error or "The request signature we calculated does not match the signature you provided" error?

A `SignatureDoesNotMatch` error indicates that the signature generated by the AWS SDK for Java and the signature generated by the AWS service do not match. The following items describe potential causes.

- A proxy or intermediary party modifies the request. For example, a proxy or load balancer might modify a header, path or query string that was signed by the SDK.
- The service and SDK differ in the way they encode the request when each generates the string to sign.

To debug this issue, we recommend that you [enable debug logging](#) for the SDK. Try to reproduce the error and find the canonical request that the SDK generated. In the log, the canonical request is labeled with `AWS4 Canonical Request: . . .` and the string to sign is labeled `AWS4 String to sign:`

If you cannot enable debugging—for example, because it's only reproducible in production—add logic to your application that logs information about the request when the error occurs. You can then use that information to try to replicate the error outside of production in an integration test with debug logging enabled.

After you have collected the canonical request and string to sign, compare them against the [AWS Signature Version 4 specification](#) to determine if there are any issues in the way the SDK generated the string to sign. If something seems wrong, you can create a [GitHub bug report](#) to the AWS SDK for Java.

If nothing appears wrong, you can compare the SDK's string to sign with the string to sign that some AWS services return as part of the failure response (Amazon S3, for example) . If this isn't available, you should [contact the affected service](#) to see what canonical request and string to sign they generated for comparison. These comparisons can help to identify intermediary parties that might have modified the request or encoding differences between the service and client.

For more background information about signing requests, see [Signing AWS API requests](#) in the AWS Identity and Access Management User Guide.

Example of a canonical request

```
PUT
/Example-Bucket/Example-Object
partNumber=19&uploadId=string
amz-sdk-invocation-id:f8c2799d-367c-f024-e8fa-6ad6d0a1afb9
amz-sdk-request:attempt=1; max=4
content-encoding:aws-chunked
content-length:51
content-type:application/octet-stream
host:xxxxx
x-amz-content-sha256:STREAMING-UNSIGNED-PAYLOAD-TRAILER
x-amz-date:20240308T034733Z
x-amz-decoded-content-length:10
x-amz-sdk-checksum-algorithm:CRC32
x-amz-trailer:x-amz-checksum-crc32
```

Example of a string to sign

```
AWS4-HMAC-SHA256
20240308T034435Z
20240308/us-east-1/s3/aws4_request
5f20a7604b1ef65dd89c333fd66736fdef9578d11a4f5d22d289597c387dc713
```

How do I fix "java.lang.IllegalStateException: Connection pool shut down" error?

This error indicates the underlying Apache HTTP connection pool was closed. The following items describe potential causes.

- **The SDK client was closed prematurely.** The SDK only closes the connection pool when the associated client is closed. Be sure not to close resources while they are in use.
- **A java.lang.Error was thrown.** Errors such as `OutOfMemoryError` cause an Apache HTTP connection pool to [shut down](#). Examine your logs for error stack traces. Also review your code for places where it catches `Throwables` or `Errors` but swallows the output that prevents the error from surfacing. If your code does not report errors, rewrite the code so information is logged. The logged information helps determine the root cause of the error.
- **You attempted to use the credentials provider returned from `DefaultCredentialsProvider#create()` after it was closed.**

[DefaultCredentialsProvider#create](#) returns a singleton instance, so if it's closed and your code calls the `resolveCredentials` method, the exception is thrown after cached credentials (or token) expire.

Check your code for places where the `DefaultCredentialsProvider` is closed, as shown in the following examples.

- The singleton instance is closed by calling `DefaultCredentialsProvider#close()`.

```
DefaultCredentialsProvider defaultCredentialsProvider =
    DefaultCredentialsProvider.create(); // Singleton instance returned.
AwsCredentials credentials = defaultCredentialsProvider.resolveCredentials();

// Make calls to AWS services.

defaultCredentialsProvider.close(); // Explicit close.

// Make calls to AWS services.

// After the credentials expire, either of the following calls eventually results
// in a "Connection pool shut down" exception.
credentials = defaultCredentialsProvider.resolveCredentials();
// Or
credentials = DefaultCredentialsProvider.create().resolveCredentials();
```

- Invoke `DefaultCredentialsProvider#create()` in a try-with-resources block.

```
try (DefaultCredentialsProvider defaultCredentialsProvider =
    DefaultCredentialsProvider.create()) {
    AwsCredentials credentials = defaultCredentialsProvider.resolveCredentials();

    // Make calls to AWS services.
} // After the try-with-resources block exits, the singleton
// DefaultCredentialsProvider is closed.

// Make calls to AWS services.

DefaultCredentialsProvider defaultCredentialsProvider =
    DefaultCredentialsProvider.create(); // The closed singleton instance is returned.
// If the credentials (or token) has expired, the following call results in the
// error.
AwsCredentials credentials = defaultCredentialsProvider.resolveCredentials();
```

Create a new, non-singleton instance by calling `DefaultCredentialsProvider.builder().build()` if your code has closed the singleton instance and you need to resolve credentials by using a `DefaultCredentialsProvider`.

Use features of the AWS SDK for Java 2.x

General features

The SDK for Java 2.x contains several features that make programming against AWS services easier.

- The SDK hides the complex mechanisms behind [retrieving paginated results](#) and [polling for resources](#).
- [Asynchronous programming with non-blocking I/O](#) helps you write concurrent code with better performance. The SDK provides the benefits of [HTTP/2](#), such as reduced latency, where possible.
- The Java SDK can generate [metrics](#) to help you monitor the operational health of your applications.

Service-specific features

In addition to the general features mentioned previously, the Java SDK provides features for specific AWS services.

- **Amazon S3** – To [simplify your work with files and directories](#) with Amazon S3, the SDK provides the S3 Transfer Manager. To [improve performance and reliability](#) while using the SDK's standard asynchronous S3 API, the SDK offers the AWS CRT-based S3 client.
- **DynamoDB** – [Object-oriented, mapping capability](#) is provided by the DynamoDB Enhanced Client API. [Work with JSON-style, document-oriented data](#) by using the Enhanced Document API.
- **IAM** – The IAM Policy Builder API provides a [type-safe, object-oriented way to create IAM policies](#).

Work with paginated results using the AWS SDK for Java 2.x

Many AWS operations return paginated results when the response object is too large to return in a single response. In the AWS SDK for Java 1.0, the response contains a token you use to retrieve the next page of results. In contrast, the AWS SDK for Java 2.x has autopagination methods that make multiple service calls to get the next page of results for you automatically. You only have to write code that processes the results. Autopagination is available for both synchronous and asynchronous clients.

Note

These code snippets assume that you understand [the basics of using the SDK](#), and have configured your environment with [single sign-on access](#).

Synchronous pagination

The following examples demonstrate synchronous pagination methods to list objects in an Amazon S3 bucket.

Iterate over pages

The first example demonstrates the use of a `listRes` paginator object, a [ListObjectsV2Iterable](#) instance, to iterate through all the response pages with the `stream` method. The code streams over the response pages, converts the response stream to a stream of [S3Object](#) content, and then processes the content of the Amazon S3 object.

The following imports apply to all examples in this synchronous pagination section.

Imports

```
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Random;

import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.paginators.ListObjectsV2Iterable;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
import software.amazon.awssdk.services.s3.model.S3Object;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadRequest;
```

```
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.CompleteMultipartUploadRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;
```

```
ListObjectsV2Request listReq = ListObjectsV2Request.builder()
    .bucket(bucketName)
    .maxKeys(1)
    .build();

ListObjectsV2Iterable listRes = s3.listObjectsV2Paginator(listReq);
// Process response pages
listRes.stream()
    .flatMap(r -> r.contents().stream())
    .forEach(content -> System.out
        .println(" Key: " + content.key() + " size = " + content.size()));
```

See the [complete example](#) on GitHub.

Iterate over objects

The following examples show ways to iterate over the objects returned in the response instead of the pages of the response. The `contents` method of `ListObjectsV2Iterable` class returns an [SdkIterable](#) that provides several methods to process the underlying content elements.

Use a stream

The following snippet uses the `stream` method on the response content to iterate over the paginated item collection.

```
// Helper method to work with paginated collection of items directly.
listRes.contents().stream()
    .forEach(content -> System.out
        .println(" Key: " + content.key() + " size = " + content.size()));
```

See the [complete example](#) on GitHub.

Use a for-each loop

Since `SdkIterable` extends the `Iterable` interface, you can process the contents like any `Iterable`. The following snippet uses standard for-each loop to iterate through the contents of the response.

```
for (S3Object content : listRes.contents()) {
    System.out.println(" Key: " + content.key() + " size = " + content.size());
}
```

See the [complete example](#) on GitHub.

Manual pagination

If your use case requires it, manual pagination is still available. Use the next token in the response object for the subsequent requests. The following example uses a while loop.

```
ListObjectsV2Request listObjectsReqManual = ListObjectsV2Request.builder()
    .bucket(bucketName)
    .maxKeys(1)
    .build();

boolean done = false;
while (!done) {
    ListObjectsV2Response listObjResponse =
s3.listObjectsV2(listObjectsReqManual);
    for (S3Object content : listObjResponse.contents()) {
        System.out.println(content.key());
    }

    if (listObjResponse.nextContinuationToken() == null) {
        done = true;
    }

    listObjectsReqManual = listObjectsReqManual.toBuilder()
        .continuationToken(listObjResponse.nextContinuationToken())
        .build();
}
```

See the [complete example](#) on GitHub.

Asynchronous pagination

The following examples demonstrate asynchronous pagination methods to list DynamoDB tables.

Iterate over pages of table names

The following two examples use an asynchronous DynamoDB client that call the `listTablesPaginator` method with a request to get a [ListTablesPublisher](#). `ListTablesPublisher` implements two interfaces, which provides many options to process responses. We'll look at methods of each interface.

Use a Subscriber

The following code example demonstrates how to process paginated results by using the `org.reactivestreams.Publisher` interface implemented by `ListTablesPublisher`. To learn more about the reactive streams model, see the [Reactive Streams GitHub repo](#).

The following imports apply to all examples in this asynchronous pagination section.

Imports

```
import io.reactivex.rxjava3.core.Flowable;
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import reactor.core.publisher.Flux;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import software.amazon.awssdk.services.dynamodb.paginators.ListTablesPublisher;

import java.util.List;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.ExecutionException;
```

The following code acquires a `ListTablesPublisher` instance.

```
// Creates a default client with credentials and region loaded from the
// environment.
final DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();
```

```
ListTablesRequest listTablesRequest =
ListTablesRequest.builder().limit(3).build();
ListTablesPublisher publisher =
asyncClient.listTablesPaginator(listTablesRequest);
```

The following code uses an anonymous implementation of `org.reactivestreams.Subscriber` to process the results for each page.

The `onSubscribe` method calls the `Subscription.request` method to initiate requests for data from the publisher. This method must be called to start getting data from the publisher.

The subscriber's `onNext` method processes a response page by accessing all the table names and printing out each one. After the page is processed, another page is requested from the publisher. This method that is called repeatedly until all pages are retrieved.

The `onError` method is triggered if an error occurs while retrieving data. Finally, the `onComplete` method is called when all pages have been requested.

```
// A Subscription represents a one-to-one life-cycle of a Subscriber
subscribing
// to a Publisher.
publisher.subscribe(new Subscriber<ListTablesResponse>() {
// Maintain a reference to the subscription object, which is required to
request
// data from the publisher.
private Subscription subscription;

@Override
public void onSubscribe(Subscription s) {
subscription = s;
// Request method should be called to demand data. Here we request a
single
// page.
subscription.request(1);
}

@Override
public void onNext(ListTablesResponse response) {
response.tableNames().forEach(System.out::println);
// After you process the current page, call the request method to
signal that
// you are ready for next page.
```

```
        subscription.request(1);
    }

    @Override
    public void onError(Throwable t) {
        // Called when an error has occurred while processing the requests.
    }

    @Override
    public void onComplete() {
        // This indicates all the results are delivered and there are no more
pages
        // left.
    }
});
```

See the [complete example](#) on GitHub.

Use a Consumer

The `SdkPublisher` interface that `ListTablesPublisher` implements has a `subscribe` method that takes a `Consumer` and returns a `CompletableFuture<Void>`.

The `subscribe` method from this interface can be used for simple use cases when an `org.reactivestreams.Subscriber` might be too much overhead. As the code below consumes each page, it calls the `tableNames` method on each. The `tableNames` method returns a `java.util.List` of DynamoDB table names that are processed with the `forEach` method.

```
// Use a Consumer for simple use cases.
CompletableFuture<Void> future = publisher.subscribe(
    response -> response.tableNames()
        .forEach(System.out::println));
```

See the [complete example](#) on GitHub.

Iterate over table names

The following examples show ways to iterate over the objects returned in the response instead of the pages of the response. Similar to the synchronous Amazon S3 example previously shown with its `contents` method, the DynamoDB asynchronous result class, `ListTablesPublisher` has the `tableNames` convenience method to interact with the underlying item collection. The return

type of the `tableNames` method is an [SdkPublisher](#) that can be used to request items across all pages.

Use a Subscriber

The following code acquires an `SdkPublisher` of the underlying collection of table names.

```
// Create a default client with credentials and region loaded from the
// environment.
final DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();

ListTablesRequest listTablesRequest =
ListTablesRequest.builder().limit(3).build();
ListTablesPublisher listTablesPublisher =
asyncClient.listTablesPaginator(listTablesRequest);
SdkPublisher<String> publisher = listTablesPublisher.tableNames();
```

The following code uses an anonymous implementation of `org.reactivestreams.Subscriber` to process the results for each page.

The subscriber's `onNext` method processes an individual element of the collection. In this case, it's a table name. After the table name is processed, another table name is requested from the publisher. This method that is called repeatedly until all table names are retrieved.

```
// Use a Subscriber.
publisher.subscribe(new Subscriber<String>() {
    private Subscription subscription;

    @Override
    public void onSubscribe(Subscription s) {
        subscription = s;
        subscription.request(1);
    }

    @Override
    public void onNext(String tableName) {
        System.out.println(tableName);
        subscription.request(1);
    }

    @Override
    public void onError(Throwable t) {
    }
}
```

```
        @Override
        public void onComplete() {
        }
    });
```

See the [complete example](#) on GitHub.

Use a Consumer

The following example uses the `subscribe` method of `SdkPublisher` that takes a `Consumer` to process each item.

```
// Use a Consumer.
CompletableFuture<Void> future = publisher.subscribe(System.out::println);
future.get();
```

See the [complete example](#) on GitHub.

Use third-party library

You can use other third party libraries instead of implementing a custom subscriber. This example demonstrates the use of RxJava, but any library that implements the reactive stream interfaces can be used. See the [RxJava wiki page on GitHub](#) for more information on that library.

To use the library, add it as a dependency. If using Maven, the example shows the POM snippet to use.

POM Entry

```
<dependency>
  <groupId>io.reactivex.rxjava3</groupId>
  <artifactId>rxjava</artifactId>
  <version>3.1.6</version>
</dependency>
```

Code

```
DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();
ListTablesPublisher publisher =
asyncClient.listTablesPaginator(ListTablesRequest.builder()
    .build());
```

```
// The Flowable class has many helper methods that work with
// an implementation of an org.reactivestreams.Publisher.
List<String> tables = Flowable.fromPublisher(publisher)
    .flatMapIterable(ListTablesResponse::tableNames)
    .toList()
    .blockingGet();
System.out.println(tables);
```

See the [complete example](#) on GitHub.

Poll for resource states in the AWS SDK for Java 2.x: Waiters

The waiters utility of the AWS SDK for Java 2.x enables you to validate that AWS resources are in a specified state before performing operations on those resources.

A *waiter* is an abstraction used to poll AWS resources, such as DynamoDB tables or Amazon S3 buckets, until a desired state is reached (or until a determination is made that the resource won't ever reach the desired state). Instead of writing logic to continuously poll your AWS resources, which can be cumbersome and error-prone, you can use waiters to poll a resource and have your code continue to run after the resource is ready.

Prerequisites

Before you can use waiters in a project with the AWS SDK for Java, you must complete the steps in [Setting up the AWS SDK for Java 2.x](#).

You must also configure your project dependencies (for example, in your `pom.xml` or `build.gradle` file) to use version `2.15.0` or later of the AWS SDK for Java.

For example:

```
<project>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>2.27.21</version>
        <type>pom</type>
        <scope>import</scope>
```

```
    </dependency>
  </dependencies>
</dependencyManagement>
</project>
```

Using waiters

To instantiate a waiters object, first create a service client. Set the service client's `waiter()` method as the value of the waiter object. Once the waiter instance exists, set its response options to execute the appropriate code.

Synchronous programming

The following code snippet shows how to wait for a DynamoDB table to exist and be in an **ACTIVE** state.

```
DynamoDbClient dynamo = DynamoDbClient.create();
DynamoDbWaiter waiter = dynamo.waiter();

WaiterResponse<DescribeTableResponse> waiterResponse =
    waiter.waitUntilTableExists(r -> r.tableName("myTable"));

// print out the matched response with a tableStatus of ACTIVE
waiterResponse.matched().response().ifPresent(System.out::println);
```

Asynchronous programming

The following code snippet shows how to wait for a DynamoDB table to no longer exist.

```
DynamoDbAsyncClient asyncDynamo = DynamoDbAsyncClient.create();
DynamoDbAsyncWaiter asyncWaiter = asyncDynamo.waiter();

CompletableFuture<WaiterResponse<DescribeTableResponse>> waiterResponse =
    asyncWaiter.waitUntilTableNotExists(r -> r.tableName("myTable"));

waiterResponse.whenComplete((r, t) -> {
    if (t == null) {
        // print out the matched ResourceNotFoundException
        r.matched().exception().ifPresent(System.out::println);
    }
}).join();
```

Configure waiters

You can customize the configuration for a waiter by using the `overrideConfiguration()` on its builder. For some operations, you can apply a custom configuration when you make the request.

Configure a waiter

The following code snippet shows how to override the configuration on a waiter.

```
// sync
DynamoDbWaiter waiter =
    DynamoDbWaiter.builder()
        .overrideConfiguration(b -> b.maxAttempts(10))
        .client(dynamoDbClient)
        .build();

// async
DynamoDbAsyncWaiter asyncWaiter =
    DynamoDbAsyncWaiter.builder()
        .client(dynamoDbAsyncClient)
        .overrideConfiguration(o -> o.backoffStrategy(
            FixedDelayBackoffStrategy.create(Duration.ofSeconds(2))))
        .scheduledExecutorService(Executors.newScheduledThreadPool(3))
        .build();
```

Override configuration for a specific request

The following code snippet shows how to override the configuration for a waiter on a per-request basis. Note that only some operations have customizable configurations.

```
waiter.waitUntilTableNotExists(b -> b.tableName("myTable"),
    o -> o.maxAttempts(10));

asyncWaiter.waitUntilTableExists(b -> b.tableName("myTable"),
    o -> o.waitTimeout(Duration.ofMinutes(1)));
```

Code examples

For a complete example using waiters with DynamoDB, see [CreateTable.java](#) in the AWS Code Examples Repository.

For a complete example using waiters with Amazon S3, see [S3BucketOps.java](#) in the AWS Code Examples Repository.

Use asynchronous programming

The AWS SDK for Java 2.x features asynchronous clients with non-blocking I/O support that implement high concurrency across a few threads. However, total non-blocking I/O is not guaranteed. Asynchronous client may perform blocking calls in some cases such as credential retrieval, request signing using [AWS Signature Version 4 \(SigV4\)](#), or endpoint discovery.

Synchronous methods block your thread's execution until the client receives a response from the service. Asynchronous methods return immediately, giving control back to the calling thread without waiting for a response.

Because an asynchronous method returns before a response is available, you need a way to get the response when it's ready. The methods for asynchronous client in 2.x of the AWS SDK for Java return *CompletableFuture* objects that allow you to access the response when it's ready.

Use asynchronous client APIs

The signatures of asynchronous client methods are the same their synchronous counterpart, but the asynchronous methods return a [CompletableFuture](#) object that contains the results of the asynchronous operation *in the future*. If an error is thrown while the SDK's asynchronous method executes, the error is thrown as `CompletionException`.

One approach you can use to get the result is to chain a `whenComplete()` method onto the `CompletableFuture` returned by the SDK method call. The `whenComplete()` method receives the result or a `Throwable` object of type `CompletionException` depending on how the asynchronous call completed. You provide an action to `whenComplete()` to process or check the results before it is returned to the calling code.

If you want to return something other than the object returned by the SDK method, use the `handle()` method instead. The `handle()` method takes the same parameters as `whenComplete()`, but you can process the result and return an object.

To wait for the asynchronous chain to complete and retrieve the completion results, you can call the `join()` method. If the `Throwable` object was not handled in the chain, the `join()` method throws an unchecked `CompletionException` that wraps the original exception. You access the original exception with `CompletionException#getCause()`. You can also call the `CompletableFuture#get()` method to get the completion results. The `get()` method, however, can throw checked exceptions.

The following example shows two variations of how you can work with the `listTables()` method of the DynamoDB asynchronous client. The action passed to `whenComplete()` simply logs a successful response, whereas the `handle()` version extracts the list of table names and returns the list. In both cases if an error is generated in the asynchronous chain, the error is rethrown so the client code has a chance to handle it.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;

import java.util.List;
import java.util.concurrent.CompletableFuture;
```

Code

whenComplete() variation

```
public class DynamoDbAsyncListTables {

    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        DynamoDbAsyncClient dynamoDbAsyncClient =
        DynamoDbAsyncClient.builder().region(region).build();
        try {
            ListTablesResponse listTablesResponse =
            listTablesWhenComplete(dynamoDbAsyncClient).join(); // The join() method may throw
            a CompletionException.
            if (listTablesResponse.hasTableNames()){
                System.out.println("Table exist in this region: " + region.id());
            }
        } catch (RuntimeException e) {
            // Handle as needed. Here we simply print out the class names.
            System.out.println(e.getClass()); // Prints 'class
            java.util.concurrent.CompletionException'.
            System.out.println(e.getCause().getClass()); // Prints 'class
            software.amazon.awssdk.services.dynamodb.model.DynamoDbException'.
        }
    }
}
```

```

    public static CompletableFuture<ListTablesResponse>
listTablesWhenComplete(DynamoDbAsyncClient client) {
    return client.listTables(ListTablesRequest.builder().build())
        .whenComplete((listTablesResponse, throwable) -> {
            if (listTablesResponse != null) { // Consume the response.
                System.out.println("The SDK's listTables method completed
successfully.");
            } else {
                RuntimeException cause = (RuntimeException)
throwable.getCause(); // If an error was thrown during the SDK's listTables method
it is wrapped in a CompletionException.

                // The SDK throws only RuntimeExceptions, so this is a safe cast.
                System.out.println(cause.getMessage()); // Log error here, but
rethrow so the calling code can handle as needed.
                throw cause;
            }
        });
}

```

handle() variation

```

public class DynamoDbAsyncListTables {

    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        DynamoDbAsyncClient dynamoDbAsyncClient =
DynamoDbAsyncClient.builder().region(region).build();
        try {
            List<String> tableNames =
listTablesHandle(dynamoDbAsyncClient).join(); // The join() method may throw a
CompletionException.
            tableNames.forEach(System.out::println);
        } catch (RuntimeException e) {
            // Handle as needed. Here we simply print out the class names.
            System.out.println(e.getClass()); // Prints 'class
java.util.concurrent.CompletionException'.
            System.out.println(e.getCause().getClass()); // Prints 'class
software.amazon.awssdk.services.dynamodb.model.DynamoDbException'.
        }
    }
}

```

```
public static CompletableFuture<List<String>>
listTablesHandle(DynamoDbAsyncClient client) {
    return client.listTables(ListTablesRequest.builder().build())
        .handle((listTablesResponse, throwable) -> {
            if (listTablesResponse != null) {
                return listTablesResponse.tableNames(); // Return the list of
table names.
            } else {
                RuntimeException cause = (RuntimeException)
throwable.getCause(); // If an error was thrown during the SDK's listTables method
it is wrapped in a CompletionException.

                // The SDK throws only RuntimeExceptions, so this is a safe cast.
                System.out.println(cause.getMessage()); // Log error here, but
rethrow so the calling code can handle as needed.
                throw cause;
            }
        });
}
```

Handle streaming in asynchronous methods

For asynchronous methods with streaming content, you must provide an [AsyncRequestBody](#) to provide the content incrementally, or an [AsyncResponseTransformer](#) to receive and process the response.

The following example uploads a file to Amazon S3 asynchronously by using the asynchronous form of the PutObject operation.

Imports

```
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;
import java.nio.file.Paths;
import java.util.concurrent.CompletableFuture;
```

Code

```
/**
 * To run this AWS code example, ensure that you have setup your development
 * environment, including your AWS credentials.
 *
 * For information, see this documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class S3AsyncOps {

    public static void main(String[] args) {

        final String USAGE = "\n" +
            "Usage:\n" +
            "  S3AsyncOps <bucketName> <key> <path>\n\n" +
            "Where:\n" +
            "  bucketName - the name of the Amazon S3 bucket (for example,
bucket1). \n\n" +
            "  key - the name of the object (for example, book.pdf). \n" +
            "  path - the local path to the file (for example, C:/AWS/book.pdf).
\n" ;

        if (args.length != 3) {
            System.out.println(USAGE);
            System.exit(1);
        }

        String bucketName = args[0];
        String key = args[1];
        String path = args[2];

        Region region = Region.US_WEST_2;
        S3AsyncClient client = S3AsyncClient.builder()
            .region(region)
            .build();

        PutObjectRequest objectRequest = PutObjectRequest.builder()
            .bucket(bucketName)
            .key(key)
            .build();

        // Put the object into the bucket
    }
}
```

```
    CompletableFuture<PutObjectResponse> future = client.putObject(objectRequest,
        AsyncRequestBody.fromFile(Paths.get(path))
    );
    future.whenComplete((resp, err) -> {
        try {
            if (resp != null) {
                System.out.println("Object uploaded. Details: " + resp);
            } else {
                // Handle error
                err.printStackTrace();
            }
        } finally {
            // Only close the client when you are completely done with it
            client.close();
        }
    });

    future.join();
}
}
```

The following example gets a file from Amazon S3 by using the asynchronous form of the `GetObject` operation.

Imports

```
import software.amazon.awssdk.core.async.AsyncResponseTransformer;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.GetObjectResponse;
import java.nio.file.Paths;
import java.util.concurrent.CompletableFuture;
```

Code

```
/**
 * To run this AWS code example, ensure that you have setup your development
 * environment, including your AWS credentials.
 *
 * For information, see this documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

```

```
*/

public class S3AsyncStreamOps {

    public static void main(String[] args) {

        final String USAGE = "\n" +
            "Usage:\n" +
            "    S3AsyncStreamOps <bucketName> <objectKey> <path>\n\n" +
            "Where:\n" +
            "    bucketName - the name of the Amazon S3 bucket (for example,
bucket1). \n\n" +
            "    objectKey - the name of the object (for example, book.pdf). \n" +
            "    path - the local path to the file (for example, C:/AWS/book.pdf).
\n" ;

        if (args.length != 3) {
            System.out.println(USAGE);
            System.exit(1);
        }

        String bucketName = args[0];
        String objectKey = args[1];
        String path = args[2];

        Region region = Region.US_WEST_2;
        S3AsyncClient client = S3AsyncClient.builder()
            .region(region)
            .build();

        GetObjectRequest objectRequest = GetObjectRequest.builder()
            .bucket(bucketName)
            .key(objectKey)
            .build();

        CompletableFuture<GetObjectResponse> futureGet =
client.getObject(objectRequest,
    AsyncResponseTransformerToFile(Paths.get(path)));

        futureGet.whenComplete((resp, err) -> {
            try {
                if (resp != null) {
                    System.out.println("Object downloaded. Details: "+resp);
                } else {

```

```
        err.printStackTrace();
    }
    } finally {
        // Only close the client when you are completely done with it
        client.close();
    }
    });
    futureGet.join();
}
}
```

Configure advanced asynchronous options

The AWS SDK for Java 2.x uses [Netty](#), an asynchronous event-driven network application framework, to handle I/O threads. The AWS SDK for Java 2.x creates an `ExecutorService` behind Netty, to complete the futures returned from the HTTP client request through to the Netty client. This abstraction reduces the risk of an application breaking the async process if developers choose to stop or sleep threads. By default, each asynchronous client creates a threadpool based on the number of processors and manages the tasks in a queue within the `ExecutorService`.

You can specify a specific JDK implementation of `ExecutorService` when you build your asynchronous client. The following snippet create an `ExecutorService` with a fixed number of threads.

Code

```
S3AsyncClient clientThread = S3AsyncClient.builder()
    .asyncConfiguration(
        b -> b.advancedOption(SdkAdvancedAsyncClientOption
            .FUTURE_COMPLETION_EXECUTOR,
            Executors.newFixedThreadPool(10)
        )
    )
    .build();
```

To optimize performance, you can manage your own thread pool executor, and include it when you configure your client.

```
ThreadPoolExecutor executor = new ThreadPoolExecutor(50, 50,
    10, TimeUnit.SECONDS,
    new LinkedBlockingQueue<>(<custom_value>),
```

```
new ThreadFactoryBuilder()
    .threadNamePrefix("sdk-async-response").build());

// Allow idle core threads to time out
executor.allowCoreThreadTimeOut(true);

S3AsyncClient clientThread = S3AsyncClient.builder()
    .asyncConfiguration(
        b -> b.advancedOption(SdkAdvancedAsyncClientOption
            .FUTURE_COMPLETION_EXECUTOR,
            executor
        )
    )
    .build();
```

Work with HTTP/2 in the AWS SDK for Java

HTTP/2 is a major revision of the HTTP protocol. This new version has several enhancements to improve performance:

- Binary data encoding provides more efficient data transfer.
- Header compression reduces the overhead bytes downloaded by the client, helping get the content to the client sooner. This is especially useful for mobile clients that are already constrained on bandwidth.
- Bidirectional asynchronous communication (multiplexing) allows multiple requests and response messages between the client and AWS to be in flight at the same time over a single connection, instead of over multiple connections, which improves performance.

Developers upgrading to the latest SDKs will automatically use HTTP/2 when it's supported by the service they're working with. New programming interfaces seamlessly take advantage of HTTP/2 features and provide new ways to build applications.

The AWS SDK for Java 2.x features new APIs for event streaming that implement the HTTP/2 protocol. For examples of how to use these new APIs, see [Working with Kinesis](#).

Publish SDK metrics from the AWS SDK for Java

With the AWS SDK for Java 2.x, you can collect metrics about the service clients and requests in your application, analyze the output in Amazon CloudWatch, and then act on it.

By default, metrics collection is disabled in the SDK. This topic helps you to enable and configure it.

What are the different `MetricPublisher` implementations?

The SDK for Java 2.x offers three implementations of the [MetricPublisher](#) interface. Each implementation is geared for different use cases and shown in the following table:

MetricPublisher implementation	Suitable use case
CloudWatchMetricPublisher	Long-running applications
EmfMetricLoggingPublisher	AWS Lambda functions
LoggingMetricPublisher	Console output for troubleshooting

Publish SDK metrics for long-running applications

Because the [CloudWatchMetricPublisher](#) implementation aggregates and periodically uploads metrics to Amazon CloudWatch with a delay, its use is best suited for long-running applications.

The default settings of the metrics publisher are meant to minimize memory usage and CloudWatch cost, while still providing a useful amount of insight into the metric data.

Set-up

Before you can enable and use metrics by using `CloudWatchMetricPublisher`, complete the following steps.

Step 1: Add required dependency

Configure your project dependencies (for example, in your `pom.xml` or `build.gradle` file) to use version `2.14.0` or later of the AWS SDK for Java.

Include the artifactId `cloudwatch-metric-publisher` with the version number `2.14.0` or later in your project's dependencies.

For example:

```
<project>
```

```

<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.30.11</version>  <!-- Navigate the link to see the latest version.
-->
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>cloudwatch-metric-publisher</artifactId>
  </dependency>
</dependencies>
</project>

```

Step 2: Configure required permissions

Enable `cloudwatch:PutMetricData` permissions for the IAM identity used by the metrics publisher to allow the SDK for Java to write metrics.

Enable metrics for a specific request

The following class shows how to enable the CloudWatch metrics publisher for a request to Amazon DynamoDB. It uses the default metrics publisher configuration.

```

import software.amazon.awssdk.metrics.MetricPublisher;
import software.amazon.awssdk.metrics.publishers.cloudwatch.CloudWatchMetricPublisher;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;

public class DefaultConfigForRequest {
    // Use one MetricPublisher for your application. It can be used with requests or
    // service clients.
    static MetricPublisher metricsPub = CloudWatchMetricPublisher.create();

    public static void main(String[] args) {
        DynamoDbClient ddb = DynamoDbClient.create();
        // Publish metrics the for ListTables operation.
    }
}

```

```
ddb.listTables(ListTablesRequest.builder()
    .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
    .build());

// Perform more work in your application.

// A MetricsPublisher has its own lifecycle independent of any service client
or request that uses it.
// If you no longer need the publisher, close it to free up resources.
metricsPub.close(); // All metrics stored in memory are flushed to CloudWatch.

// Perform more work with the DynamoDbClient instance without publishing
metrics.
// Close the service client when you no longer need it.
ddb.close();
}
}
```

Important

Make sure your application calls `close` on the [MetricPublisher](#) instance when the service client is no longer in use. Failure to do so results in possible thread or file descriptor leaks.

Enable summary metrics for a specific service client

The following code snippet shows how to enable a CloudWatch metrics publisher with default settings for a service client.

```
MetricPublisher metricsPub = CloudWatchMetricPublisher.create();

DynamoDbClient ddb = DynamoDbClient.builder()
    .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
    .build();
```

Customize a CloudWatch metrics publisher

The following class demonstrates how to set up a custom configuration for the metrics publisher for a specific service client. The customizations include loading a specific profile, specifying a AWS

Region where the metrics publisher sends requests, and customizing how often the publisher sends metrics to CloudWatch.

```
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.core.metrics.CoreMetric;
import software.amazon.awssdk.metrics.MetricPublisher;
import software.amazon.awssdk.metrics.publishers.cloudwatch.CloudWatchMetricPublisher;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchAsyncClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

import java.time.Duration;

public class CustomConfigForDDBClient {
    // Use one MetricPublisher for your application. It can be used with requests or
    // service clients.
    static MetricPublisher metricsPub = CloudWatchMetricPublisher.builder()
        .cloudWatchClient(CloudWatchAsyncClient.builder()
            .region(Region.US_WEST_2)
            .credentialsProvider(ProfileCredentialsProvider.create("cloudwatch"))
            .build())
        .uploadFrequency(Duration.ofMinutes(5))
        .maximumCallsPerUpload(100)
        .namespace("ExampleSDKV2Metrics")
        .detailedMetrics(CoreMetric.API_CALL_DURATION)
        .build();

    public static void main(String[] args) {
        DynamoDbClient ddb = DynamoDbClient.builder()
            .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
            .build();
        // Publish metrics for DynamoDB operations.
        ddb.listTables();
        ddb.describeEndpoints();
        ddb.describeLimits();
        // Perform more work in your application.

        // A MetricsPublisher has its own lifecycle independent of any service client
        // or request that uses it.
        // If you no longer need the publisher, close it to free up resources.
        metricsPub.close(); // All metrics stored in memory are flushed to CloudWatch.
    }
}
```

```
        // Perform more work with the DynamoDbClient instance without publishing
metrics.
        // Close the service client when you no longer need it.
        ddb.close();
    }
}
```

The customizations shown in the previous snippet have the following effects.

- The `cloudWatchClient` method lets you customize the CloudWatch client used to send metrics. In this example, we use a different region from the default of *us-east-1* where the client sends metrics. We also use a different named profile, *cloudwatch*, whose credentials will be used to authenticate requests to CloudWatch. Those credentials must have permissions to `cloudwatch:PutMetricData`.
- The `uploadFrequency` method allows you to specify how frequently the metrics publisher uploads metrics to CloudWatch. The default is once a minute.
- The `maximumCallsPerUpload` method limits the number of calls made per upload. The default is unlimited.
- By default, the SDK for Java 2.x publishes metrics under the namespace `AwsSdk/JavaSdk2`. You can use the `namespace` method to specify a different value.
- By default, the SDK publishes summary metrics. Summary metrics consist of average, minimum, maximum, sum, and sample count. By specifying one or more SDK metrics in the `detailedMetrics` method, the SDK publishes additional data for each metric. This additional data enables percentile statistics like p90 and p99 that you can query in CloudWatch. The detailed metrics are especially useful for latency metrics like `APICallDuration`, which measures the end-to-end latency for SDK client requests. You can use fields of the [CoreMetric](#) class to specify other common SDK metrics.

Publish SDK metrics for AWS Lambda functions

Because Lambda functions typically execute for milliseconds to minutes, any delay in sending the metrics, which happens with the `CloudWatchMetricPublisher`, risks the loss of data.

[EmfMetricLoggingPublisher](#) provides a more suitable approach by immediately writing metrics as structured log entries in [CloudWatch Embedded Metric Format \(EMF\)](#).

`EmfMetricLoggingPublisher` works in execution environments that have built-in integration with Amazon CloudWatch Logs such as AWS Lambda and Amazon Elastic Container Service.

Set-up

Before you can enable and use metrics by using `EmfMetricLoggingPublisher`, complete the following steps.

Step 1: Add required dependency

Configure your project dependencies (for example, in your `pom.xml` or `build.gradle` file) to use version `2.30.3` or later of the AWS SDK for Java.

Include the artifactId `emf-metric-logging-publisher` with the version number `2.30.3` or later in your project's dependencies.

For example:

```
<project>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>2.30.11</version>  <!-- Navigate the link to see the latest version.
-->
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>emf-metric-logging-publisher</artifactId>
    </dependency>
  </dependencies>
</project>
```

Step 2: Configure required permissions

Enable logs : `PutLogEvents` permissions for the IAM identity used by the metrics publisher to allow the SDK for Java to write EMF-formatted logs.

Step 3: Setup logging

To ensure proper metric collection, configure your logging to output to the console at the INFO level or lower (such as DEBUG). In your `log4j2.xml` file:

```
<Loggers>
  <Root level="WARN">
    <AppenderRef ref="ConsoleAppender"/>
  </Root>
  <Logger
name="software.amazon.awssdk.metrics.publishers.emf.EmfMetricLoggingPublisher"
level="INFO" />
</Loggers>
```

See the [logging topic](#) in this guide for more information on how to set up a `log4j2.xml` file.

Configure and use `EmfMetricLoggingPublisher`

The following Lambda function class first creates and configures an `EmfMetricLoggingPublisher` instance and then uses it with a Amazon DynamoDB service client:

```
public class GameIdHandler implements RequestHandler<Map<String, String>, String> {
    private final EmfMetricLoggingPublisher emfPublisher;
    private final DynamoDbClient dynamoDb;

    public GameIdHandler() {
        // Build the publisher.
        this.emfPublisher = EmfMetricLoggingPublisher.builder()
            .namespace("namespace")
            .dimensions(CoreMetric.SERVICE_ID,
                CoreMetric.OPERATION_NAME)
            .build();
        // Add the publisher to the client.
        this.dynamoDb = DynamoDbClient.builder()
            .overrideConfiguration(c -> c.addMetricPublisher(emfPublisher))
            .region(Region.of(System.getenv("AWS_REGION")))
            .build();
    }

    @Override
    public String handleRequest(Map<String, String> event, Context context) {
```

```
Map<String, AttributeValue> gameItem = new HashMap<>();

gameItem.put("gameId", AttributeValue.builder().s(event.get("id")).build());

PutItemRequest putItemRequest = PutItemRequest.builder()
    .tableName("games")
    .item(gameItem)
    .build();

dynamoDb.putItem(putItemRequest);

return "Request handled";
}
}
```

When the DynamoDB client executes the `putItem` method, it automatically publishes metrics to a CloudWatch log stream in EMF format.

The [API documentation](#) for `EmfMetricLoggingPublisher.Builder` shows the configuration options that you can use.

You can also enable EMF metric logging for a single request as [shown for the CloudWatchMetricPublisher](#).

When are metrics available?

Metrics are generally available within 5-10 minutes after the SDK for Java emits them. For accurate and up-to-date metrics, check Cloudwatch at least 10 minutes after emitting the metrics from your Java applications.

What information is collected?

Metrics collection includes the following:

- Number of API requests, including whether they succeed or fail
- Information about the AWS services you call in your API requests, including exceptions returned
- The duration for various operations such as Marshalling, Signing, and HTTP requests
- HTTP client metrics, such as the number of open connections, the number of pending requests, and the name of the HTTP client used

Note

The metrics available vary by HTTP client.

For a complete list, see [Service client metrics](#).

How can I use this information?

You can use the metrics the SDK collects to monitor the service clients in your application. You can look at overall usage trends, identify anomalies, review service client exceptions returned, or to dig in to understand a particular issue. Using Amazon CloudWatch, you can also create alarms to notify you as soon as your application reaches a condition that you define.

For more information, see [Using Amazon CloudWatch Metrics](#) and [Using Amazon CloudWatch Alarms](#) in the [Amazon CloudWatch User Guide](#).

Service client metrics

With the AWS SDK for Java 2.x, you can collect metrics from the service clients in your application and then publish (output) those metrics to [Amazon CloudWatch](#).

These tables list the metrics that you can collect and any HTTP client usage requirement.

For more information about enabling and configuring metrics for the SDK, see [Enabling SDK metrics](#).

Metrics collected with each request

Metric name	Description	Type
ApiCallDuration	The total time taken to finish a request (inclusive of all retries).	Duration*
ApiCallSuccessful	True if the API call was successful; false if not.	Boolean

Metric name	Description	Type
CredentialsFetchDuration	The time taken to fetch AWS signing credentials for the request.	Duration*
EndpointResolveDuration	The duration of time it took to resolve the endpoint used for the API call.	Duration*
MarshallingDuration	The time it takes to marshall an SDK request to an HTTP request.	Duration*
OperationName	The name of the AWS API the request is made to.	String
RetryCount	Number of times the SDK retried the API call.	Integer
ServiceId	Service ID of the AWS service that the API request is made against.	String
TokenFetchDuration	The time taken to fetch token signing credentials for the request.	Duration*

*[java.time.Duration](#).

Metrics collected for each request attempt

Each API call might require multiple attempts before a response is received. These metrics are collected for each attempt.

Core metrics

Metric name	Description	Type
AwsExtendedRequestId	The extended request ID of the service request.	String
AwsRequestId	The request ID of the service request.	String
BackoffDelayDuration	The duration of time the SDK waited before this API call attempt.	Duration*
ErrorType	The type of error that occurred for a call attempt.	String
ReadThroughput	The read throughput of the client in bytes/second.	Double
ServiceCallDuration	The time it takes to connect to the service, send the request, and receive the HTTP status code and header from the response.	Duration*
SigningDuration	The time it takes to sign the HTTP request.	Duration*
TimeToFirstByte	Elapsed time from sending the HTTP request (including acquiring a connection) to receiving the first byte of the headers in the response.	Duration*
TimeToLastByte	Elapsed time from sending the HTTP request (including acquiring a connection) to	Duration*

Metric name	Description	Type
	receiving the last byte of the response.	
UnmarshallingDuration	The time it takes to unmarshall an HTTP response to an SDK response.	Duration*

*[java.time.Duration](#).

HTTP Metrics

Metric name	Description	Type	HTTP client required*
AvailableConcurrency	The number of remaining concurrent requests that can be supported by the HTTP client without needing to establish another connection.	Integer	Apache, Netty, CRT
ConcurrencyAcquireDuration	The time taken to acquire a channel from the connection pool.	Duration*	Apache, Netty, CRT
HttpClientName	The name of the HTTP being use for the request.	String	Apache, Netty, CRT
HttpStatuscode	The status code returned with the HTTP response.	Integer	Any

Metric name	Description	Type	HTTP client required*
LeasedConcurrency	The number of request currently being executed by the HTTP client.	Integer	Apache, Netty, CRT
LocalStreamWindowSize	The local HTTP/2 window size in bytes for the stream that this request was executed on.	Integer	Netty
MaxConcurrency	The max number of concurrent requests supported by the HTTP client.	Integer	Apache, Netty, CRT
PendingConcurrencyAcquires	The number of requests that are blocked, waiting for another TCP connection or a new stream to be available from the connection pool.	Integer	Apache, Netty, CRT
RemoteStreamWindowSize	The remote HTTP/2 window size in bytes for the stream that this request was executed on.	Integer	Netty

*[java.time.Duration](#).

The terms used in the column mean:

- Apache: the Apache-based HTTP client ([ApacheHttpClient](#))
- Netty: the Netty-based HTTP client ([NettyNioAsyncHttpClient](#))
- CRT: the AWS CRT-based HTTP client ([AwsCrtAsyncHttpClient](#))
- Any: the collection of metric data does not depend on the HTTP client; this includes the URLConnection-based HTTP client ([URLConnectionHttpClient](#))

Work with AWS services using the AWS SDK for Java 2.x

This section provides short tutorials and guidance for how to work with select AWS services. For a complete set of examples, see the [Code Examples section](#).

Work with CloudWatch

This section provides examples of programming [Amazon CloudWatch](#) by using the AWS SDK for Java 2.x.

Amazon CloudWatch monitors your Amazon Web Services (AWS) resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications. CloudWatch alarms send notifications or automatically make changes to the resources you are monitoring based on rules that you define.

The following examples include only the code needed to demonstrate each technique. The [complete example code is available on GitHub](#). From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- [Get metrics from CloudWatch](#)
- [Publish custom metric data to CloudWatch](#)
- [Work with CloudWatch alarms](#)
- [Use Amazon CloudWatch Events](#)

Get metrics from CloudWatch

Listing metrics

To list CloudWatch metrics, create a [ListMetricsRequest](#) and call the `CloudWatchClient`'s `listMetrics` method. You can use the `ListMetricsRequest` to filter the returned metrics by namespace, metric name, or dimensions.

Note

A list of metrics and dimensions that are posted by AWS services can be found within the [Amazon CloudWatch Metrics and Dimensions Reference](#) in the Amazon CloudWatch User Guide.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsRequest;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsResponse;
import software.amazon.awssdk.services.cloudwatch.model.Metric;
```

Code

```
public static void listMets( CloudWatchClient cw, String namespace) {

    boolean done = false;
    String nextToken = null;

    try {
        while(!done) {
```

```
ListMetricsResponse response;

if (nextToken == null) {
    ListMetricsRequest request = ListMetricsRequest.builder()
        .namespace(namespace)
        .build();

    response = cw.listMetrics(request);
} else {
    ListMetricsRequest request = ListMetricsRequest.builder()
        .namespace(namespace)
        .nextToken(nextToken)
        .build();

    response = cw.listMetrics(request);
}

for (Metric metric : response.metrics()) {
    System.out.printf(
        "Retrieved metric %s", metric.metricName());
    System.out.println();
}

if(response.nextToken() == null) {
    done = true;
} else {
    nextToken = response.nextToken();
}
}

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

The metrics are returned in a [ListMetricsResponse](#) by calling its `getMetrics` method.

The results may be *paged*. To retrieve the next batch of results, call `nextToken` on the response object and use the token value to build a new request object. Then call the `listMetrics` method again with the new request.

See the [complete example](#) on GitHub.

More information

- [ListMetrics](#) in the Amazon CloudWatch API Reference

Publish custom metric data to CloudWatch

A number of AWS services publish [their own metrics](#) in namespaces beginning with " AWS ". You can also publish custom metric data using your own namespace (as long as it doesn't begin with " AWS ").

Publish custom metric data

To publish your own metric data, call the CloudWatchClient's putMetricData method with a [PutMetricDataRequest](#). The PutMetricDataRequest must include the custom namespace to use for the data, and information about the data point itself in a [MetricDatum](#) object.

Note

You cannot specify a namespace that begins with " AWS ". Namespaces that begin with " AWS " are reserved for use by Amazon Web Services products.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.Dimension;
import software.amazon.awssdk.services.cloudwatch.model.MetricDatum;
import software.amazon.awssdk.services.cloudwatch.model.StandardUnit;
import software.amazon.awssdk.services.cloudwatch.model.PutMetricDataRequest;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import java.time.Instant;
import java.time.ZoneOffset;
import java.time.ZonedDateTime;
import java.time.format.DateTimeFormatter;
```

Code

```
public static void putMetData(CloudWatchClient cw, Double dataPoint ) {
```

```
try {
    Dimension dimension = Dimension.builder()
        .name("UNIQUE_PAGES")
        .value("URLS")
        .build();

    // Set an Instant object
    String time =
ZonedDateTime.now( ZoneOffset.UTC ).format( DateTimeFormatter.ISO_INSTANT );
    Instant instant = Instant.parse(time);

    MetricDatum datum = MetricDatum.builder()
        .metricName("PAGES_VISITED")
        .unit(StandardUnit.NONE)
        .value(dataPoint)
        .timestamp(instant)
        .dimensions(dimension).build();

    PutMetricDataRequest request = PutMetricDataRequest.builder()
        .namespace("SITE/TRAFFIC")
        .metricData(datum).build();

    cw.putMetricData(request);

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
System.out.printf("Successfully put data point %f", dataPoint);
}
```

See the [complete example](#) on GitHub.

More information

- [Use Amazon CloudWatch Metrics](#) in the Amazon CloudWatch User Guide.
- [AWS Namespaces](#) in the Amazon CloudWatch User Guide.
- [PutMetricData](#) in the Amazon CloudWatch API Reference.

Work with CloudWatch alarms

Create an alarm

To create an alarm based on a CloudWatch metric, call the `CloudWatchClient`'s `putMetricAlarm` method with a [PutMetricAlarmRequest](#) filled with the alarm conditions.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.Dimension;
import software.amazon.awssdk.services.cloudwatch.model.PutMetricAlarmRequest;
import software.amazon.awssdk.services.cloudwatch.model.ComparisonOperator;
import software.amazon.awssdk.services.cloudwatch.model.Statistic;
import software.amazon.awssdk.services.cloudwatch.model.StandardUnit;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
```

Code

```
public static void putMetricAlarm(CloudWatchClient cw, String alarmName, String
instanceId) {

    try {
        Dimension dimension = Dimension.builder()
            .name("InstanceId")
            .value(instanceId).build();

        PutMetricAlarmRequest request = PutMetricAlarmRequest.builder()
            .alarmName(alarmName)
            .comparisonOperator(
                ComparisonOperator.GREATER_THAN_THRESHOLD)
            .evaluationPeriods(1)
            .metricName("CPUUtilization")
            .namespace("AWS/EC2")
            .period(60)
            .statistic(Statistic.AVERAGE)
            .threshold(70.0)
            .actionsEnabled(false)
            .alarmDescription(
                "Alarm when server CPU utilization exceeds 70%")
            .unit(StandardUnit.SECONDS)
            .dimensions(dimension)
```

```
        .build();

        cw.putMetricAlarm(request);
        System.out.printf(
            "Successfully created alarm with name %s", alarmName);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

List alarms

To list the CloudWatch alarms that you have created, call the `CloudWatchClient`'s `describeAlarms` method with a [DescribeAlarmsRequest](#) that you can use to set options for the result.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DescribeAlarmsRequest;
import software.amazon.awssdk.services.cloudwatch.model.DescribeAlarmsResponse;
import software.amazon.awssdk.services.cloudwatch.model.MetricAlarm;
```

Code

```
public static void desCWAAlarms( CloudWatchClient cw) {

    try {

        boolean done = false;
        String newToken = null;

        while(!done) {
            DescribeAlarmsResponse response;

            if (newToken == null) {
```

```
        DescribeAlarmsRequest request =
DescribeAlarmsRequest.builder().build();
        response = cw.describeAlarms(request);
    } else {
        DescribeAlarmsRequest request = DescribeAlarmsRequest.builder()
            .nextToken(newToken)
            .build();
        response = cw.describeAlarms(request);
    }

    for(MetricAlarm alarm : response.metricAlarms()) {
        System.out.printf("\n Retrieved alarm %s", alarm.alarmName());
    }

    if(response.nextToken() == null) {
        done = true;
    } else {
        newToken = response.nextToken();
    }
}

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
System.out.printf("Done");
}
```

The list of alarms can be obtained by calling `MetricAlarms` on the [DescribeAlarmsResponse](#) that is returned by `describeAlarms`.

The results may be *paged*. To retrieve the next batch of results, call `nextToken` on the response object and use the token value to build a new request object. Then call the `describeAlarms` method again with the new request.

Note

You can also retrieve alarms for a specific metric by using the `CloudWatchClient`'s `describeAlarmsForMetric` method. Its use is similar to `describeAlarms`.

See the [complete example](#) on GitHub.

Delete alarms

To delete CloudWatch alarms, call the `CloudWatchClient`'s `deleteAlarms` method with a [DeleteAlarmsRequest](#) containing one or more names of alarms that you want to delete.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DeleteAlarmsRequest;
```

Code

```
public static void deleteCWAlarm(CloudWatchClient cw, String alarmName) {
    try {
        DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
            .alarmNames(alarmName)
            .build();

        cw.deleteAlarms(request);
        System.out.printf("Successfully deleted alarm %s", alarmName);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

More information

- [Using Amazon CloudWatch alarms](#) in the Amazon CloudWatch User Guide
- [PutMetricAlarm](#) in the Amazon CloudWatch API Reference
- [DescribeAlarms](#) in the Amazon CloudWatch API Reference
- [DeleteAlarms](#) in the Amazon CloudWatch API Reference

Use Amazon CloudWatch Events

CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources to Amazon EC2 instances, Lambda functions, Kinesis streams, Amazon ECS tasks, Step Functions state machines, Amazon SNS topics, Amazon SQS queues, or built-in targets. You can match events and route them to one or more target functions or streams by using simple rules.

Amazon EventBridge is the [evolution](#) of CloudWatch Events. Both services use the same API, so you can continue using the [CloudWatch Events client](#) provided by the SDK or migrate to the SDK for Java's [EventBridge client](#) for CloudWatch Events functionality. CloudWatch Events [User Guide documentation](#) and [API reference](#) are now available through the EventBridge documentation sites.

Add events

To add custom CloudWatch events, call the `CloudWatchEventsClient`'s `putEvents` method with a [PutEventsRequest](#) object that contains one or more [PutEventsRequestEntry](#) objects that provide details about each event. You can specify several parameters for the entry such as the source and type of the event, resources associated with the event, and so on.

Note

You can specify a maximum of 10 events per call to `putEvents`.

Imports

```
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutEventsRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutEventsRequestEntry;
```

Code

```
public static void putCWEvents(CloudWatchEventsClient cwe, String resourceArn ) {

    try {

        final String EVENT_DETAILS =
            "{ \"key1\": \"value1\", \"key2\": \"value2\" }";

        PutEventsRequestEntry requestEntry = PutEventsRequestEntry.builder()
```

```
        .detail(EVENT_DETAILS)
        .detailType("sampleSubmitted")
        .resources(resourceArn)
        .source("aws-sdk-java-cloudwatch-example")
        .build();

    PutEventsRequest request = PutEventsRequest.builder()
        .entries(requestEntry)
        .build();

    cwe.putEvents(request);
    System.out.println("Successfully put CloudWatch event");

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Add rules

To create or update a rule, call the `CloudWatchEventsClient`'s `putRule` method with a [PutRuleRequest](#) with the name of the rule and optional parameters such as the [event pattern](#), IAM role to associate with the rule, and a [scheduling expression](#) that describes how often the rule is run.

Imports

```
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutRuleRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutRuleResponse;
import software.amazon.awssdk.services.cloudwatchevents.model.RuleState;
```

Code

```
public static void putCWRule(CloudWatchEventsClient cwe, String ruleName, String
roleArn) {

    try {
        PutRuleRequest request = PutRuleRequest.builder()
```

```
        .name(ruleName)
        .roleArn(roleArn)
        .scheduleExpression("rate(5 minutes)")
        .state(RuleState.ENABLED)
        .build();

    PutRuleResponse response = cwe.putRule(request);
    System.out.printf(
        "Successfully created CloudWatch events rule %s with arn %s",
        roleArn, response.ruleArn());
} catch (
    CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Add targets

Targets are the resources that are invoked when a rule is triggered. Example targets include Amazon EC2 instances, Lambda functions, Kinesis streams, Amazon ECS tasks, Step Functions state machines, and built-in targets.

To add a target to a rule, call the `CloudWatchEventsClient`'s `putTargets` method with a [PutTargetsRequest](#) containing the rule to update and a list of targets to add to the rule.

Imports

```
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutTargetsRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutTargetsResponse;
import software.amazon.awssdk.services.cloudwatchevents.model.Target;
```

Code

```
public static void putCWTargets(CloudWatchEventsClient cwe, String ruleName, String
functionArn, String targetId ) {

    try {
        Target target = Target.builder()
```

```
        .arn(functionArn)
        .id(targetId)
        .build();

    PutTargetsRequest request = PutTargetsRequest.builder()
        .targets(target)
        .rule(ruleName)
        .build();

    PutTargetsResponse response = cwe.putTargets(request);
    System.out.printf(
        "Successfully created CloudWatch events target for rule %s",
        ruleName);
} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

AWS database services and AWS SDK for Java 2.x

AWS offers several database types: relational, key-value, in-memory, document, and [several others](#). The SDK for Java 2.x support varies depending the nature of the database service in AWS.

Some database services, for example [Amazon DynamoDB](#) service, have web service APIs to manage the AWS resource (database) as well as web service APIs to interact with the data. In the SDK for Java 2.x these types of services have dedicated service clients, for example [DynamoDBClient](#).

Other database services have web service APIs that interact with the resource, such the [Amazon DocumentDB](#) API (for cluster, instance and resource management), but do not have a web service API for working with the data. The SDK for Java 2.x has a corresponding [DocDbClient](#) interface for working with the resource. However, you need another Java API, such as [MongoDB for Java](#) to work with the data.

Use the examples below to learn how you use the SDK for Java 2.x service clients with the different types of databases.

Amazon DynamoDB examples

Working with the data

SDK service client: [DynamoDbClient](#)

Example: [React/Spring REST application using DynamoDB](#)

Examples: [Several DynamoDB examples](#)

SDK service client: [DynamoDbEnhancedClient](#)

Example: [React/Spring REST application using DynamoDB](#)

Examples: [Several DynamoDB examples](#)
(names starting with 'Enhanced')

Working with the database

SDK service client: [DynamoDbClient](#)

Examples: [CreateTable](#), [ListTables](#), [DeleteTable](#)

See [additional DynamoDB examples](#) in the guided code examples section of this guide.

Amazon RDS examples

Working with the data	Working with the database
Non-SDK API: JDBC, database-specific SQL flavor; your code manages database connections or a connection pool.	SDK service client: RdsClient

Working with the data	Working with the database
Example: React/Spring REST application using MySQL	Examples: Several RdsClient examples

Amazon Redshift examples

Working with the data	Working with the database
SDK service client: RedshiftDataClient	SDK service client: RedshiftClient
Examples: Several RedshiftDataClient examples	Examples: Several RedshiftClient examples
Example: React/Spring REST application using RedshiftDataClient

Working with the data	Working with the database
SDK service client: RdsDataClient	SDK service client: RdsClient
Example: React/Spring REST application using RdsDataClient	Examples: Several RdsClient examples

Amazon DocumentDB examples

Working with the data	Working with the database
Non-SDK API: MongoDB-specific Java library (for example MongoDB for Java); your code manages database connections or a connection pool.	SDK service client: DocDbClient

Working with the data	Working with the database
Examples: DocumentDB (Mongo) Developer Guide (select 'Java' tab)	

Work with DynamoDB

This section provides examples that show you how to work with [DynamoDB](#).

The following examples use the standard, low-level DynamoDB client ([DynamoDbClient](#)) of the AWS SDK for Java 2.x.

- [the section called “Work with tables in DynamoDB”](#)
- [the section called “Work with items in DynamoDB”](#)

The SDK also offers the [DynamoDB Enhanced Client](#) that provides a high-level, object-oriented approach for working with DynamoDB. The following section discusses this client in depth.

- [the section called “ Map objects to DynamoDB items”](#)

Use AWS account-based endpoints

DynamoDB offers [AWS account-based endpoints](#) that can improve performance by using your AWS account ID to streamline request routing.

To take advantage of this feature, you need to use version 2.28.4 or greater of version 2 of AWS SDK for Java. You can find the latest version of the SDK listed in the [Maven central repository](#). After a supported version of SDK is active, it automatically uses the new endpoints.

If you want to opt out of the account-based routing, you have four options:

- Configure a DynamoDB service client with the `AccountIdEndpointMode` set to `DISABLED`.
- Set an environment variable.
- Set a JVM system property.
- Update the shared AWS config file setting.

The following snippet is an example of how to disable account-based routing by configuring a DynamoDB service client:

```
DynamoDbClient.builder()  
    .accountIdEndpointMode(AccountIdEndpointMode.DISABLED)  
    .build();
```

The AWS SDKs and Tools Reference Guide provides more information on the last [three configuration options](#).

Work with tables in DynamoDB

Tables are the containers for all items in a DynamoDB database. Before you can add or remove data from DynamoDB, you must create a table.

For each table, you must define:

- A table *name* that is unique for your account and Region.
- A *primary key* for which every value must be unique; no two items in your table can have the same primary key value.

A primary key can be *simple*, consisting of a single partition (HASH) key, or *composite*, consisting of a partition and a sort (RANGE) key.

Each key value has an associated *data type*, enumerated by the [ScalarAttributeType](#) class. The key value can be binary (B), numeric (N), or a string (S). For more information, see [Naming Rules and Data Types](#) in the Amazon DynamoDB Developer Guide.

- *Provisioned throughput* are values that define the number of reserved read/write capacity units for the table.

Note

[Amazon DynamoDB pricing](#) is based on the provisioned throughput values that you set on your tables, so reserve only as much capacity as you think you'll need for your table.

Provisioned throughput for a table can be modified at any time, so you can adjust capacity as your needs change.

Create a table

Use the `DynamoDbClient`'s `createTable` method to create a new DynamoDB table. You need to construct table attributes and a table schema, both of which are used to identify the primary key of your table. You must also supply initial provisioned throughput values and a table name.

Note

If a table with the name you chose already exists, a [DynamoDbException](#) is thrown.

Create a table with a simple primary key

This code creates a table with one attribute that is the table's simple primary key. The example uses [AttributeDefinition](#) and [KeySchemaElement](#) objects for the [CreateTableRequest](#).

Imports

```
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableRequest;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableResponse;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.waiters.DynamoDbWaiter;
```

Code

```
public static String createTable(DynamoDbClient ddb, String tableName, String key)
{
    DynamoDbWaiter dbWaiter = ddb.waiter();
    CreateTableRequest request = CreateTableRequest.builder()
        .attributeDefinitions(AttributeDefinition.builder()
```

```

        .attributeName(key)
        .attributeType(ScalarAttributeType.S)
        .build())
    .keySchema(KeySchemaElement.builder()
        .attributeName(key)
        .keyType(KeyType.HASH)
        .build())
    .provisionedThroughput(ProvisionedThroughput.builder()
        .readCapacityUnits(new Long(10))
        .writeCapacityUnits(new Long(10))
        .build())
    .tableName(tableName)
    .build();

String newTable = "";
try {
    CreateTableResponse response = ddb.createTable(request);
    DescribeTableRequest tableRequest = DescribeTableRequest.builder()
        .tableName(tableName)
        .build();

    // Wait until the Amazon DynamoDB table is created
    WaiterResponse<DescribeTableResponse> waiterResponse =
dbWaiter.waitUntilTableExists(tableRequest);
    waiterResponse.matched().response().ifPresent(System.out::println);

    newTable = response.tableDescription().tableName();
    return newTable;

} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
return "";
}

```

See the [complete example](#) on GitHub.

Create a table with a composite primary key

The following example creates a table with two attributes. Both attributes are used for the composite primary key.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
```

Code

```
public static String createTableComKey(DynamoDbClient ddb, String tableName) {
    CreateTableRequest request = CreateTableRequest.builder()
        .attributeDefinitions(
            AttributeDefinition.builder()
                .attributeName("Language")
                .attributeType(ScalarAttributeType.S)
                .build(),
            AttributeDefinition.builder()
                .attributeName("Greeting")
                .attributeType(ScalarAttributeType.S)
                .build())
        .keySchema(
            KeySchemaElement.builder()
                .attributeName("Language")
                .keyType(KeyType.HASH)
                .build(),
            KeySchemaElement.builder()
                .attributeName("Greeting")
                .keyType(KeyType.RANGE)
                .build())
        .provisionedThroughput(
            ProvisionedThroughput.builder()
                .readCapacityUnits(new Long(10))
                .writeCapacityUnits(new Long(10)).build())
        .tableName(tableName)
        .build();

    String tableId = "";

    try {
```

```
        CreateTableResponse result = ddb.createTable(request);
        tableId = result.tableDescription().tableId();
        return tableId;
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
```

See the [complete example](#) on GitHub.

List tables

You can list the tables in a particular Region by calling the `DynamoDbClient`'s `listTables` method.

Note

If the named table doesn't exist for your account and Region, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import java.util.List;
```

Code

```
public static void listAllTables(DynamoDbClient ddb){

    boolean moreTables = true;
    String lastName = null;

    while(moreTables) {
```

```
try {
    ListTablesResponse response = null;
    if (lastName == null) {
        ListTablesRequest request = ListTablesRequest.builder().build();
        response = ddb.listTables(request);
    } else {
        ListTablesRequest request = ListTablesRequest.builder()
            .exclusiveStartTableName(lastName).build();
        response = ddb.listTables(request);
    }

    List<String> tableNames = response.tableNames();

    if (tableNames.size() > 0) {
        for (String curName : tableNames) {
            System.out.format("* %s\n", curName);
        }
    } else {
        System.out.println("No tables found!");
        System.exit(0);
    }

    lastName = response.lastEvaluatedTableName();
    if (lastName == null) {
        moreTables = false;
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}
System.out.println("\nDone!");
}
```

By default, up to 100 tables are returned per call—use `lastEvaluatedTableName` on the returned [ListTablesResponse](#) object to get the last table that was evaluated. You can use this value to start the listing after the last returned value of the previous listing.

See the [complete example](#) on GitHub.

Describe (get information about) a table

Use the `DynamoDbClient`'s `describeTable` method to get information about a table.

Note

If the named table doesn't exist for your account and Region, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableRequest;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughputDescription;
import software.amazon.awssdk.services.dynamodb.model.TableDescription;
import java.util.List;
```

Code

```
public static void describeDynamoDBTable(DynamoDbClient ddb, String tableName ) {

    DescribeTableRequest request = DescribeTableRequest.builder()
        .tableName(tableName)
        .build();

    try {
        TableDescription tableInfo =
            ddb.describeTable(request).table();

        if (tableInfo != null) {
            System.out.format("Table name   : %s\n",
                tableInfo.tableName());
            System.out.format("Table ARN   : %s\n",
                tableInfo.tableArn());
            System.out.format("Status      : %s\n",
                tableInfo.tableStatus());
            System.out.format("Item count  : %d\n",
                tableInfo.itemCount().longValue());
            System.out.format("Size (bytes): %d\n",
                tableInfo.tableSizeBytes().longValue());

            ProvisionedThroughputDescription throughputInfo =
```

```
        tableInfo.provisionedThroughput();
        System.out.println("Throughput");
        System.out.format("  Read Capacity : %d\n",
            throughputInfo.readCapacityUnits().longValue());
        System.out.format("  Write Capacity: %d\n",
            throughputInfo.writeCapacityUnits().longValue());

        List<AttributeDefinition> attributes =
            tableInfo.attributeDefinitions();
        System.out.println("Attributes");

        for (AttributeDefinition a : attributes) {
            System.out.format("  %s (%s)\n",
                a.attributeName(), a.attributeType());
        }
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
System.out.println("\nDone!");
}
```

See the [complete example](#) on GitHub.

Modify (update) a table

You can modify your table's provisioned throughput values at any time by calling the `DynamoDbClient`'s `updateTable` method.

Note

If the named table doesn't exist for your account and Region, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.UpdateTableRequest;
```

```
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

Code

```
public static void updateDynamoDBTable(DynamoDbClient ddb,
                                       String tableName,
                                       Long readCapacity,
                                       Long writeCapacity) {

    System.out.format(
        "Updating %s with new provisioned throughput values\n",
        tableName);
    System.out.format("Read capacity : %d\n", readCapacity);
    System.out.format("Write capacity : %d\n", writeCapacity);

    ProvisionedThroughput tableThroughput = ProvisionedThroughput.builder()
        .readCapacityUnits(readCapacity)
        .writeCapacityUnits(writeCapacity)
        .build();

    UpdateTableRequest request = UpdateTableRequest.builder()
        .provisionedThroughput(tableThroughput)
        .tableName(tableName)
        .build();

    try {
        ddb.updateTable(request);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }

    System.out.println("Done!");
}
```

See the [complete example](#) on GitHub.

Delete a table

To delete a table, call `DynamoDbClient`'s `deleteTable` method and provide the table's name.

Note

If the named table doesn't exist for your account and Region, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DeleteTableRequest;
```

Code

```
public static void deleteDynamoDBTable(DynamoDbClient ddb, String tableName) {

    DeleteTableRequest request = DeleteTableRequest.builder()
        .tableName(tableName)
        .build();

    try {
        ddb.deleteTable(request);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    System.out.println(tableName + " was successfully deleted!");
}
```

See the [complete example](#) on GitHub.

More information

- [Guidelines for Working with Tables](#) in the Amazon DynamoDB Developer Guide
- [Working with Tables in DynamoDB](#) in the Amazon DynamoDB Developer Guide

Work with items in DynamoDB

In DynamoDB, an item is a collection of *attributes*, each of which has a *name* and a *value*. An attribute value can be a scalar, set, or document type. For more information, see [Naming Rules and Data Types](#) in the Amazon DynamoDB Developer Guide.

Retrieve (get) an item from a table

Call the `DynamoDbClient`'s `getItem` method and pass it a [GetItemRequest](#) object with the table name and primary key value of the item you want. It returns a [GetItemResponse](#) object with all of the attributes for that item. You can specify one or more [projection expressions](#) in the `GetItemRequest` to retrieve specific attributes.

You can use the returned `GetItemResponse` object's `item()` method to retrieve a [Map](#) of key (`String`) and value ([AttributeValue](#)) pairs that are associated with the item.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;
```

Code

```
public static void getDynamoDBItem(DynamoDbClient ddb, String tableName, String
key, String keyVal ) {

    HashMap<String, AttributeValue> keyToGet = new HashMap<String, AttributeValue>();

    keyToGet.put(key, AttributeValue.builder()
        .s(keyVal).build());

    GetItemRequest request = GetItemRequest.builder()
        .key(keyToGet)
        .tableName(tableName)
        .build();
```

```
try {
    Map<String,AttributeValue> returnedItem = ddb.getItem(request).item();

    if (returnedItem != null) {
        Set<String> keys = returnedItem.keySet();
        System.out.println("Amazon DynamoDB table attributes: \n");

        for (String key1 : keys) {
            System.out.format("%s: %s\n", key1,
returnedItem.get(key1).toString());
        }
    } else {
        System.out.format("No item found with the key %s!\n", key);
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Retrieve (get) an item from a table using the asynchronous client

Invoke the `getItem` method of the `DynamoDbAsyncClient` and pass it a [GetItemRequest](#) object with the table name and primary key value of the item you want.

You can return a [Collection](#) instance with all of the attributes for that item (refer to the following example).

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;
import java.util.stream.Collectors;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

Code

```
public static void getItem(DynamoDbAsyncClient client, String tableName, String
key, String keyVal) {

    HashMap<String, AttributeValue> keyToGet =
        new HashMap<String, AttributeValue>();

    keyToGet.put(key, AttributeValue.builder()
        .s(keyVal).build());

    try {

        // Create a GetItemRequest instance
        GetItemRequest request = GetItemRequest.builder()
            .key(keyToGet)
            .tableName(tableName)
            .build();

        // Invoke the DynamoDbAsyncClient object's getItem
        java.util.Collection<AttributeValue> returnedItem =
client.getItem(request).join().item().values();

        // Convert Set to Map
        Map<String, AttributeValue> map =
returnedItem.stream().collect(Collectors.toMap(AttributeValue::s, s->s));
        Set<String> keys = map.keySet();
        for (String sinKey : keys) {
            System.out.format("%s: %s\n", sinKey, map.get(sinKey).toString());
        }

    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Add a new item to a table

Create a [Map](#) of key-value pairs that represent the item's attributes. These must include values for the table's primary key fields. If the item identified by the primary key already exists, its fields are *updated* by the request.

Note

If the named table doesn't exist for your account and region, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.PutItemRequest;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import java.util.HashMap;
```

Code

```
public static void putItemInTable(DynamoDbClient ddb,
                                String tableName,
                                String key,
                                String keyVal,
                                String albumTitle,
                                String albumTitleValue,
                                String awards,
                                String awardVal,
                                String songTitle,
                                String songTitleVal){

    HashMap<String,AttributeValue> itemValues = new
HashMap<String,AttributeValue>();

    // Add all content to the table
    itemValues.put(key, AttributeValue.builder().s(keyVal).build());
    itemValues.put(songTitle, AttributeValue.builder().s(songTitleVal).build());
    itemValues.put(albumTitle,
AttributeValue.builder().s(albumTitleValue).build());
    itemValues.put(awards, AttributeValue.builder().s(awardVal).build());

    PutItemRequest request = PutItemRequest.builder()
        .tableName(tableName)
        .item(itemValues)
```

```
        .build();

    try {
        ddb.putItem(request);
        System.out.println(tableName + " was successfully updated");
    } catch (ResourceNotFoundException e) {
        System.err.format("Error: The Amazon DynamoDB table \"%s\" can't be found.
\n", tableName);
        System.err.println("Be sure that it exists and that you've typed its name
correctly!");
        System.exit(1);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Update an existing item in a table

You can update an attribute for an item that already exists in a table by using the `DynamoDbClient`'s `updateItem` method, providing a table name, primary key value, and a map of fields to update.

Note

If the named table doesn't exist for your account and region, or if the item identified by the primary key you passed in doesn't exist, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.AttributeAction;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.AttributeValueUpdate;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
```

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import java.util.HashMap;
```

Code

```
public static void updateTableItem(DynamoDbClient ddb,
                                   String tableName,
                                   String key,
                                   String keyVal,
                                   String name,
                                   String updateVal){

    HashMap<String,AttributeValue> itemKey = new HashMap<String,AttributeValue>();

    itemKey.put(key, AttributeValue.builder().s(keyVal).build());

    HashMap<String,AttributeValueUpdate> updatedValues =
        new HashMap<String,AttributeValueUpdate>();

    // Update the column specified by name with updatedVal
    updatedValues.put(name, AttributeValueUpdate.builder()
        .value(AttributeValue.builder().s(updateVal).build())
        .action(AttributeAction.PUT)
        .build());

    UpdateItemRequest request = UpdateItemRequest.builder()
        .tableName(tableName)
        .key(itemKey)
        .attributeUpdates(updatedValues)
        .build();

    try {
        ddb.updateItem(request);
    } catch (ResourceNotFoundException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }

    System.out.println("Done!");
}
```

See the [complete example](#) on GitHub.

Delete an existing item in a table

You can delete an item that exists in a table by using the `DynamoDbClient`'s `deleteItem` method and providing a table name as well as the primary key value.

Note

If the named table doesn't exist for your account and region, or if the item identified by the primary key you passed in doesn't exist, a [ResourceNotFoundException](#) is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DeleteItemRequest;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import java.util.HashMap;
```

Code

```
public static void deleteDynamoDBItem(DynamoDbClient ddb, String tableName, String
key, String keyVal) {

    HashMap<String,AttributeValue> keyToGet =
        new HashMap<String,AttributeValue>();

    keyToGet.put(key, AttributeValue.builder()
        .s(keyVal)
        .build());

    DeleteItemRequest deleteReq = DeleteItemRequest.builder()
        .tableName(tableName)
        .key(keyToGet)
        .build();

    try {
        ddb.deleteItem(deleteReq);
    } catch (DynamoDbException e) {
```

```
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Map Java objects to DynamoDB items with the AWS SDK for Java 2.x

The [DynamoDB Enhanced Client API](#) is a high-level library that is the successor to the `DynamoDBMapper` class of in the SDK for Java v1.x. It offers a straightforward way to map client-side classes to DynamoDB tables. You define the relationships between tables and their corresponding data classes in your code. After you define those relationships, you can intuitively perform various create, read, update, or delete (CRUD) operations on tables or items in DynamoDB.

The DynamoDB Enhanced Client API also includes the [Enhanced Document API](#) that enables you to work with document-type items that do not follow a defined schema.

The DynamoDB Enhanced Client API is discussed in the following topics.

- [Get Started using the DynamoDB Enhanced Client API](#)
- [Learn the basics of the DynamoDB Enhanced Client API](#)
- [Use advanced mapping features](#)
- [Work with JSON documents with the Enhanced Document API for DynamoDB](#)
- [Use extensions](#)
- [Use the DynamoDB Enhanced Client API asynchronously](#)
- [Data class annotations](#)

Get Started using the DynamoDB Enhanced Client API

The following tutorial introduces you to fundamentals that you need to work with the DynamoDB Enhanced Client API.

Add dependencies

To begin working with the DynamoDB Enhanced Client API in your project, add a dependency on the dynamodb-enhanced Maven artifact. This is shown in the following examples.

Maven

```
<project>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version><VERSION></version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>dynamodb-enhanced</artifactId>
    </dependency>
  </dependencies>
  ...
</project>
```

Perform a search of the Maven central repository for the [latest version](#) and replace `<VERSION>` with this value.

Gradle

```
repositories {
    mavenCentral()
}
dependencies {
    implementation(platform("software.amazon.awssdk:bom:<VERSION>"))
    implementation("software.amazon.awssdk:dynamodb-enhanced")
    ...
}
```

Perform a search of the Maven central repository for the [latest version](#) and replace `<VERSION>` with this value.

Generate a `TableSchema` from a data class

A [TableSchema](#) enables the enhanced client to map DynamoDB attribute values to and from your client-side classes. In this tutorial, you learn about TableSchemas derived from a static data class and generated from code by using a builder.

Use an annotated data class

The SDK for Java 2.x includes a [set of annotations](#) that you can use with a data class to quickly generate a TableSchema for mapping your classes to tables.

Start by creating a data class that conforms to the [JavaBean specification](#). The specification requires that a class has a no-argument public constructor and has getters and setters for each attribute in the class. Include a class-level annotation to indicate that the data class is a `DynamoDbBean`. Also, at a minimum, include a `DynamoDbPartitionKey` annotation on the getter or setter for the primary key attribute.

You can apply [attribute-level annotations](#) to getters or setters, but not both.

Note

The term `property` is normally used for a value encapsulated in a `JavaBean`. However, this guide uses the term `attribute` instead, to be consistent with the terminology used by DynamoDB.

The following `Customer` class shows annotations that link the class definition to a DynamoDB table.

Customer class

```
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
```

```
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;

import java.time.Instant;

@DynamoDbBean
public class Customer {

    private String id;
    private String name;
    private String email;
    private Instant regDate;

    @DynamoDbPartitionKey
    public String getId() { return this.id; }

    public void setId(String id) { this.id = id; }

    public String getCustName() { return this.name; }

    public void setCustName(String name) { this.name = name; }

    @DynamoDbSortKey
    public String getEmail() { return this.email; }

    public void setEmail(String email) { this.email = email; }

    public Instant getRegistrationDate() { return this.regDate; }

    public void setRegistrationDate(Instant registrationDate) { this.regDate =
registrationDate; }

    @Override
    public String toString() {
        return "Customer [id=" + id + ", name=" + name + ", email=" + email
            + ", regDate=" + regDate + "]";
    }
}
```

After you have created an annotated data class, use it to create the `TableSchema`, as shown in the following snippet.

```
static final TableSchema<Customer> customerTableSchema =
    TableSchema.fromBean(Customer.class);
```

A `TableSchema` is designed to be static and immutable. You can usually instantiate it at class-load time.

The static `TableSchema.fromBean()` factory method introspects the bean to generate the mapping of data class attributes (properties) to and from DynamoDB attributes.

For an example of working with a data model made up of several data classes, see the `Person` class in the [???](#) section.

Use a builder

You can skip the cost of bean introspection if you define the table schema in code. If you code the schema, your class does not need to follow JavaBean naming standards nor does it need to be annotated. The following example uses a builder and is equivalent to the `Customer` class example that uses annotations.

```
static final TableSchema<Customer> customerTableSchema =
    TableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(Customer::getId)
            .setter(Customer::setId)
            .tags(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("email")
            .getter(Customer::getEmail)
            .setter(Customer::setEmail)
            .tags(StaticAttributeTags.primarySortKey()))
        .addAttribute(String.class, a -> a.name("name")
            .getter(Customer::getCustName)
            .setter(Customer::setCustName))
        .addAttribute(Instant.class, a -> a.name("registrationDate")
            .getter(Customer::getRegistrationDate)
            .setter(Customer::setRegistrationDate))
        .build();
```

Create an enhanced client and `DynamoDbTable`

Create an enhanced client

The [DynamoDbEnhancedClient](#) class or its asynchronous counterpart, [DynamoDbEnhancedAsyncClient](#), is the entry point to working with the DynamoDB Enhanced Client API.

The enhanced client requires a standard [DynamoDbClient](#) to perform work. The API offers two ways to create a `DynamoDbEnhancedClient` instance. The first option, shown in the following snippet, creates a standard `DynamoDbClient` with default settings picked up from configuration settings.

```
DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.create();
```

If you want to configure the underlying standard client, you can supply it to the enhanced client's builder method as shown in the following snippet.

```
// Configure an instance of the standard DynamoDbClient.
DynamoDbClient standardClient = DynamoDbClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();

// Use the configured standard client with the enhanced client.
DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
    .dynamoDbClient(standardClient)
    .build();
```

Create a `DynamoDbTable` instance

Think of a [DynamoDbTable](#) as the client-side representation of a DynamoDB table that uses the mapping functionality provided by a `TableSchema`. The `DynamoDbTable` class provides methods for CRUD operations that let you interact with a single DynamoDB table.

`DynamoDbTable<T>` is a generic class that takes a single type argument, whether it is a custom class or an `EnhancedDocument` when working with document-type items. This argument type establishes the relationship between the class that you use and the single DynamoDB table.

Use the `table()` factory method of the `DynamoDbEnhancedClient` to create a `DynamoDbTable` instance as shown in the following snippet.

```
static final DynamoDbTable<Customer> customerTable =
    enhancedClient.table("Customer", TableSchema.fromBean(Customer.class));
```

`DynamoDbTable` instances are candidates for singletons because they are immutable and can be used throughout your application.

Your code now has an in-memory representation of a DynamoDB table that can work with `Customer` instances. The actual DynamoDB table might or might not exist. If the table named `Customer` already exists, you can begin performing CRUD operations against it. If it doesn't exist, use the `DynamoDbTable` instance to create the table as discussed in the next section.

Create a DynamoDB table if needed

After you have created a `DynamoDbTable` instance, use it to perform a *one-time* creation of a table in DynamoDB.

Create table example code

The following example creates a DynamoDB table based on the `Customer` data class.

This example creates a DynamoDB table with the name `Customer`—identical to the class name—but the table name can be something else. Whatever you name the table, you must use this name in additional applications to work with the table. Supply this name to the `table()` method anytime you create another `DynamoDbTable` object in order to work with the underlying DynamoDB table.

The Java lambda parameter, `builder`, passed to the `createTable` method lets you [customize the table](#). In this example, [provisioned throughput](#) is configured. If you want to use default settings when you create a table, skip the builder as shown in the following snippet.

```
customerTable.createTable();
```

When default settings are used, values for provisioned throughput are not set. Instead, the billing mode for the table is set to [on-demand](#).

The example also uses a [DynamoDbWaiter](#) before attempting to print out the table name received in the response. The creation of a table takes some time. Therefore, using a waiter means you don't have to write logic that polls the DynamoDB service to see if the table exists before using the table.

Imports

```
import com.example.dynamodb.Customer;
import software.amazon.awssdk.core.internal.waiters.ResponseOrException;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedClient;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbTable;
import software.amazon.awssdk.enhanced.dynamodb.TableSchema;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableResponse;
```

```
import software.amazon.awssdk.services.dynamodb.waiters.DynamoDbWaiter;
```

Code

```
public static void createCustomerTable(DynamoDbTable<Customer> customerTable,
DynamoDbClient standardClient) {
    // Create the DynamoDB table using the 'customerTable' DynamoDbTable instance.
    customerTable.createTable(builder -> builder
        .provisionedThroughput(b -> b
            .readCapacityUnits(10L)
            .writeCapacityUnits(10L)
            .build())
    );
    // The DynamoDbClient instance (named 'standardClient') passed to the builder for
    the DynamoDbWaiter is the same instance
    // that was passed to the builder of the DynamoDbEnhancedClient instance that we
    created previously.
    // By using the same instance, it ensures that the same Region that was configured
    on the standard DynamoDbClient
    // instance is used for other service clients that accept a DynamoDbClient during
    construction.
    try (DynamoDbWaiter waiter =
DynamoDbWaiter.builder().client(standardClient).build()) { // DynamoDbWaiter is
Autocloseable
        ResponseOrException<DescribeTableResponse> response = waiter
            .waitUntilTableExists(builder ->
builder.tableName("Customer").build())
            .matched();
        DescribeTableResponse tableDescription = response.response().orElseThrow(
            () -> new RuntimeException("Customer table was not created."));
        // The actual error can be inspected in response.exception()
        logger.info("Customer table was created.");
    }
}
```

Note

A DynamoDB table's attribute names begin with a lowercase letter when the table is generated from a data class. If you want the table's attribute name to begin with an uppercase letter, use the [@DynamoDbAttribute\(*NAME*\) annotation](#) and provide the name you want as a parameter.

Perform operations

After the table is created, use the `DynamoDbTable` instance to perform operations against the DynamoDB table.

In the following example, a singleton `DynamoDbTable<Customer>` is passed as a parameter along with a [Customer data class](#) instance to add a new item to the table.

```
public static void putItemExample(DynamoDbTable<Customer> customerTable, Customer
customer){
    logger.info(customer.toString());
    customerTable.putItem(customer);
}
```

Customer object

```
Customer customer = new Customer();
customer.setId("1");
customer.setCustName("Customer Name");
customer.setEmail("customer@example.com");
customer.setRegistrationDate(Instant.parse("2023-07-03T10:15:30.00Z"));
```

Before sending the `customer` object to the DynamoDB service, log the output of the object's `toString()` method to compare it to what the enhanced client sends.

```
Customer [id=1, name=Customer Name, email=customer@example.com,
regDate=2023-07-03T10:15:30Z]
```

Wire-level logging shows the payload of the generated request. The enhanced client generated the low-level representation from the data class. The `regDate` attribute, which is an `Instant` type in Java, is represented as a DynamoDB string.

```
{
  "TableName": "Customer",
  "Item": {
    "registrationDate": {
      "S": "2023-07-03T10:15:30Z"
    },
    "id": {
      "S": "1"
    }
  }
}
```

```
    },
    "custName": {
        "S": "Customer Name"
    },
    "email": {
        "S": "customer@example.com"
    }
}
}
```

Work with an existing table

The previous section showed how to create a DynamoDB table starting with a Java data class. If you already have an existing table and want to use the features of the enhanced client, you can create a Java data class to work with the table. You need to examine the DynamoDB table and add the necessary annotations to the data class.

Before you work with an existing table, call the `DynamoDbEnhanced.table()` method. This was done in the previous example with the following statement.

```
DynamoDbTable<Customer> customerTable = enhancedClient.table("Customer",
    TableSchema.fromBean(Customer.class));
```

After the `DynamoDbTable` instance is returned, you can begin working right away with the underlying table. You do not need to recreate the table by calling the `DynamoDbTable.createTable()` method.

The following example demonstrates this by immediately retrieving a `Customer` instance from the DynamoDB table.

```
DynamoDbTable<Customer> customerTable = enhancedClient.table("Customer",
    TableSchema.fromBean(Customer.class));
// The Customer table exists already and has an item with a primary key value of "1"
// and a sort key value of "customer@example.com".
customerTable.getItem(
    Key.builder()
        .partitionValue("1")
        .sortValue("customer@example.com").build());
```

⚠ Important

The table name used in the `table()` method must match the existing DynamoDB table name.

Learn the basics of the DynamoDB Enhanced Client API

This topic discusses the basic features of the DynamoDB Enhanced Client API and compares it to the [standard DynamoDB client API](#).

If you are new to the DynamoDB Enhanced Client API, we recommend that you go through the [introductory tutorial](#) to familiarize yourself with fundamental classes.

DynamoDB items in Java

DynamoDB tables store items. Depending on your use case, items on the Java side can take the form of statically structured data or structures created dynamically.

If your use case calls for items with a consistent set of attributes, use [annotated classes](#) or use a [builder](#) to generate the appropriate statically-typed `TableSchema`.

Alternatively, if you need to store items that consist of varying structures, create a `DocumentTableSchema`. `DocumentTableSchema` is part of the [Enhanced Document API](#) and requires only a statically-typed primary key and works with `EnhancedDocument` instances to hold the data elements. The Enhanced Document API is covered in another [topic](#).

Attribute types for data model classes

Although DynamoDB supports [a small number of attribute types](#) compared to the rich type system of Java, the DynamoDB Enhanced Client API provides mechanisms to convert members of a Java class to and from DynamoDB attribute types.

The attribute types (properties) of your Java data classes should be objects types, not primitives. For example, always use `Long` and `Integer` object data types, not `long` and `int` primitives.

By default, the DynamoDB Enhanced Client API supports attribute converters for a large number of types, such as [Integer](#), [String](#), [BigDecimal](#), and [Instant](#). The list appears in the [known implementing classes of the AttributeConverter interface](#). The list includes many types and collections such as maps, lists, and sets.

To store the data for an attribute type that isn't supported by default or doesn't conform to the JavaBean convention, you can write a custom `AttributeConverter` implementation to do the conversion. See the attribute conversion section for an [example](#).

To store the data for an attribute type whose class conforms to the Java beans specification (or an [immutable data class](#)), you can take two approaches.

- If you have access to the source file, you can annotate the class with `@DynamoDbBean` (or `@DynamoDbImmutable`). The section that discusses nested attributes shows [examples](#) of using annotated classes.
- If do not have access to the source file of the JavaBean data class for the attribute (or you don't want to annotate the source file of a class that you do have access to), then you can use the builder approach. This creates a table schema without defining the keys. Then, you can nest this table schema inside another table schema to perform the mapping. The nested attribute section has an [example](#) showing use of nested schemas.

Null values

When you use the `putItem` method, the enhanced client does not include null-valued attributes of a mapped data object in the request to DynamoDB.

The SDK's default behavior for `updateItem` requests removes attributes from the item in DynamoDB that are set to null in the object that you submit in the `updateItem` method. If you intend to update some attribute values and keep the others unchanged, you have two options.

- Retrieve the item (by using `getItem`) before you make changes to values. By using this approach, the SDK submits all updated and old values to DynamoDB.
- Use either the [IgnoreNullsMode](#).`SCALAR_ONLY` or `IgnoreNullsMode`.`MAPS_ONLY` when you build the request to update the item. Both modes ignore null-valued properties in the object that represent scalar attributes in DynamoDB. The [the section called "Update items that contain complex types"](#) topic in this guide contains more information about the `IgnoreNullsMode` values and how to work with complex types.

The following example demonstrates `ignoreNullsMode()` for the `updateItem()` method.

```
public static void updateItemNullsExample() {
    Customer customer = new Customer();
```

```
customer.setCustName("CustomerName");
customer.setEmail("email");
customer.setId("1");
customer.setRegistrationDate(Instant.now());

logger.info("Original customer: {}", customer);

// Put item with values for all attributes.
try {
    customerAsyncDynamoDbTable.putItem(customer).join();
} catch (RuntimeException rte) {
    logger.error("A exception occurred during putItem: {}",
rte.getCause().getMessage(), rte);
    return;
}

// Create a Customer instance with the same 'id' and 'email' values, but a
different 'name' value.
// Do not set the 'registrationDate' attribute.
Customer customerForUpdate = new Customer();
customerForUpdate.setCustName("NewName");
customerForUpdate.setEmail("email");
customerForUpdate.setId("1");

// Update item without setting the 'registrationDate' property and set
IgnoreNullsMode to SCALAR_ONLY.
try {
    Customer updatedWithNullsIgnored = customerAsyncDynamoDbTable.updateItem(b
-> b
        .item(customerForUpdate)
        .ignoreNullsMode(IgnoreNullsMode.SCALAR_ONLY))
        .join();
    logger.info("Customer updated with nulls ignored: {}",
updatedWithNullsIgnored.toString());
} catch (RuntimeException rte) {
    logger.error("An exception occurred during updateItem: {}",
rte.getCause().getMessage(), rte);
    return;
}

// Update item without setting the registrationDate attribute and not setting
ignoreNulls to true.
try {
```

```

        Customer updatedWithNullsUsed =
customerAsyncDynamoDbTable.updateItem(customerForUpdate)
            .join();
        logger.info("Customer updated with nulls used: {}",
updatedWithNullsUsed.toString());
    } catch (RuntimeException rte) {
        logger.error("An exception occurred during updateItem: {}",
rte.getCause().getMessage(), rte);
    }
}

// Logged lines.
Original customer: Customer [id=1, name=CustomerName, email=email,
regDate=2024-10-11T14:12:30.222858Z]
Customer updated with nulls ignored: Customer [id=1, name=NewName, email=email,
regDate=2024-10-11T14:12:30.222858Z]
Customer updated with nulls used: Customer [id=1, name=NewName, email=email,
regDate=null]

```

DynamoDB Enhanced Client basic methods

Basic methods of the enhanced client map to the DynamoDB service operations that they're named after. The following examples show the simplest variation of each method. You can customize each method by passing in an enhanced request object. Enhanced request objects offer most of the features available in the standard DynamoDB client. They are fully documented in the AWS SDK for Java 2.x API Reference.

The example uses the [the section called "Customer class"](#) shown previously.

```

// CreateTable
customerTable.createTable();

// GetItem
Customer customer =
customerTable.getItem(Key.builder().partitionValue("a123").build());

// UpdateItem
Customer updatedCustomer = customerTable.updateItem(customer);

// PutItem
customerTable.putItem(customer);

```

```

// DeleteItem
Customer deletedCustomer =
    customerTable.deleteItem(Key.builder().partitionValue("a123").sortValue(456).build());

// Query
PageIterable<Customer> customers = customerTable.query(keyEqualTo(k ->
    k.partitionValue("a123")));

// Scan
PageIterable<Customer> customers = customerTable.scan();

// BatchGetItem
BatchGetResultPageIterable batchResults =
    enhancedClient.batchGetItem(r -> r.addReadBatch(ReadBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        .addGetItem(key1)
        .addGetItem(key2)
        .addGetItem(key3)
        .build()));

// BatchWriteItem
batchResults = enhancedClient.batchWriteItem(r ->
    r.addWriteBatch(WriteBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        .addPutItem(customer)
        .addDeleteItem(key1)
        .addDeleteItem(key1)
        .build()));

// TransactGetItems
transactResults = enhancedClient.transactGetItems(r -> r.addGetItem(customerTable,
    key1)
        .addGetItem(customerTable,
    key2));

// TransactWriteItems
enhancedClient.transactWriteItems(r -> r.addConditionCheck(customerTable,
    i -> i.key(orderKey)
        .conditionExpression(conditionExpression))
        .addUpdateItem(customerTable, customer)
        .addDeleteItem(customerTable, key));

```

Compare DynamoDB Enhanced Client to standard DynamoDB client

Both DynamoDB client APIs—[standard](#) and [enhanced](#)—let you work with DynamoDB tables to perform CRUD (create, read, update and delete) data-level operations. The difference between the client APIs is how that is accomplished. Using the standard client, you work directly with low-level data attributes. The enhanced client API uses familiar Java classes and maps to the low-level API behind the scenes.

While both client APIs support data-level operations, the standard DynamoDB client also supports resource-level operations. Resource-level operations manage the database, such as creating backups, listing tables, and updating tables. The enhanced client API supports a select number of resource-level operations such as creating, describing, and deleting tables.

To illustrate the different approaches used by the two client APIs, the following code examples show the creation of the same ProductCatalog table using the standard client and the enhanced client.

Compare: Create a table using the standard DynamoDB client

```
DependencyFactory.dynamoDbClient().createTable(builder -> builder
    .tableName(TABLE_NAME)
    .attributeDefinitions(
        b -> b.attributeName("id").attributeType(ScalarAttributeType.N),
        b -> b.attributeName("title").attributeType(ScalarAttributeType.S),
        b -> b.attributeName("isbn").attributeType(ScalarAttributeType.S)
    )
    .keySchema(
        builder1 -> builder1.attributeName("id").keyType(KeyType.HASH),
        builder2 -> builder2.attributeName("title").keyType(KeyType.RANGE)
    )
    .globalSecondaryIndexes(builder3 -> builder3
        .indexName("products_by_isbn")
        .keySchema(builder2 -> builder2
            .attributeName("isbn").keyType(KeyType.HASH))
        .projection(builder2 -> builder2
            .projectionType(ProjectionType.INCLUDE)
            .nonKeyAttributes("price", "authors"))
        .provisionedThroughput(builder4 -> builder4
            .writeCapacityUnits(5L).readCapacityUnits(5L))
    )
    .provisionedThroughput(builder1 -> builder1
        .readCapacityUnits(5L).writeCapacityUnits(5L))
```

```
);
```

Compare: Create a table using the DynamoDB Enhanced Client

```
DynamoDbEnhancedClient enhancedClient = DependencyFactory.enhancedClient();
productCatalog = enhancedClient.table(TABLE_NAME,
    TableSchema.fromImmutableClass(ProductCatalog.class));
productCatalog.createTable(b -> b
    .provisionedThroughput(b1 -> b1.readCapacityUnits(5L).writeCapacityUnits(5L))
    .globalSecondaryIndices(b2 -> b2.indexName("products_by_isbn")
        .projection(b4 -> b4
            .projectionType(ProjectionType.INCLUDE)
            .nonKeyAttributes("price", "authors"))
        .provisionedThroughput(b3 ->
b3.writeCapacityUnits(5L).readCapacityUnits(5L))
    );
```

The enhanced client uses the following annotated data class. The DynamoDB Enhanced Client maps Java data types to DynamoDB data types for less verbose code that is easier to follow. `ProductCatalog` is an example of using an immutable class with the DynamoDB Enhanced Client. The use of Immutable classes for mapped data classes is [discussed later](#) in this topic.

ProductCatalog class

```
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbIgnore;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbImmutable;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;

import java.math.BigDecimal;
import java.util.Objects;
import java.util.Set;

@DynamoDbImmutable(builder = ProductCatalog.Builder.class)
public class ProductCatalog implements Comparable<ProductCatalog> {
    private Integer id;
```

```
private String title;
private String isbn;
private Set<String> authors;
private BigDecimal price;

private ProductCatalog(Builder builder){
    this.authors = builder.authors;
    this.id = builder.id;
    this.isbn = builder.isbn;
    this.price = builder.price;
    this.title = builder.title;
}

public static Builder builder(){ return new Builder(); }

@DynamoDbPartitionKey
public Integer id() { return id; }

@DynamoDbSortKey
public String title() { return title; }

@DynamoDbSecondaryPartitionKey(indexNames = "products_by_isbn")
public String isbn() { return isbn; }
public Set<String> authors() { return authors; }
public BigDecimal price() { return price; }

public static final class Builder {
    private Integer id;
    private String title;
    private String isbn;
    private Set<String> authors;
    private BigDecimal price;
    private Builder(){

    public Builder id(Integer id) { this.id = id; return this; }
    public Builder title(String title) { this.title = title; return this; }
    public Builder isbn(String ISBN) { this.isbn = ISBN; return this; }
    public Builder authors(Set<String> authors) { this.authors = authors; return
this; }
    public Builder price(BigDecimal price) { this.price = price; return this; }
    public ProductCatalog build() { return new ProductCatalog(this); }
}
```

```

@Override
public String toString() {
    final StringBuffer sb = new StringBuffer("ProductCatalog{");
    sb.append("id=").append(id);
    sb.append(", title=").append(title).append('\ ');
    sb.append(", isbn=").append(isbn).append('\ ');
    sb.append(", authors=").append(authors);
    sb.append(", price=").append(price);
    sb.append('}');
    return sb.toString();
}

@Override
public boolean equals(Object o) {
    if (this == o) return true;
    if (o == null || getClass() != o.getClass()) return false;
    ProductCatalog that = (ProductCatalog) o;
    return id.equals(that.id) && title.equals(that.title) && Objects.equals(isbn,
that.isbn) && Objects.equals(authors, that.authors) && Objects.equals(price,
that.price);
}

@Override
public int hashCode() {
    return Objects.hash(id, title, isbn, authors, price);
}

@Override
@DynamoDbIgnore
public int compareTo(ProductCatalog other) {
    if (this.id.compareTo(other.id) != 0){
        return this.id.compareTo(other.id);
    } else {
        return this.title.compareTo(other.title);
    }
}
}

```

The following two code examples of a batch write illustrate the verbosity and lack of type safety when using the standard client as opposed to the enhanced client.

Compare: Batch write using the standard DynamoDB client

```
public static void batchWriteStandard(DynamoDbClient dynamoDbClient, String
tableName) {

    Map<String, AttributeValue> catalogItem = Map.of(
        "authors", AttributeValue.builder().ss("a", "b").build(),
        "id", AttributeValue.builder().n("1").build(),
        "isbn", AttributeValue.builder().s("1-565-85698").build(),
        "title", AttributeValue.builder().s("Title 1").build(),
        "price", AttributeValue.builder().n("52.13").build());

    Map<String, AttributeValue> catalogItem2 = Map.of(
        "authors", AttributeValue.builder().ss("a", "b", "c").build(),
        "id", AttributeValue.builder().n("2").build(),
        "isbn", AttributeValue.builder().s("1-208-98073").build(),
        "title", AttributeValue.builder().s("Title 2").build(),
        "price", AttributeValue.builder().n("21.99").build());

    Map<String, AttributeValue> catalogItem3 = Map.of(
        "authors", AttributeValue.builder().ss("g", "k", "c").build(),
        "id", AttributeValue.builder().n("3").build(),
        "isbn", AttributeValue.builder().s("7-236-98618").build(),
        "title", AttributeValue.builder().s("Title 3").build(),
        "price", AttributeValue.builder().n("42.00").build());

    Set<WriteRequest> writeRequests = Set.of(
        WriteRequest.builder().putRequest(b -> b.item(catalogItem)).build(),
        WriteRequest.builder().putRequest(b -> b.item(catalogItem2)).build(),
        WriteRequest.builder().putRequest(b -> b.item(catalogItem3)).build());

    Map<String, Set<WriteRequest>> productCatalogItems = Map.of(
        "ProductCatalog", writeRequests);

    BatchWriteItemResponse response = dynamoDbClient.batchWriteItem(b ->
b.requestItems(productCatalogItems));

    logger.info("Unprocessed items: " + response.unprocessedItems().size());
}
```

Compare: Batch write using the DynamoDB Enhanced Client

```
public static void batchWriteEnhanced(DynamoDbTable<ProductCatalog> productCatalog)
{
    ProductCatalog prod = ProductCatalog.builder()
        .id(1)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(52.13))
        .title("Title 1")
        .build();
    ProductCatalog prod2 = ProductCatalog.builder()
        .id(2)
        .isbn("1-208-98073")
        .authors(new HashSet<>(Arrays.asList("a", "b", "c")))
        .price(BigDecimal.valueOf(21.99))
        .title("Title 2")
        .build();
    ProductCatalog prod3 = ProductCatalog.builder()
        .id(3)
        .isbn("7-236-98618")
        .authors(new HashSet<>(Arrays.asList("g", "k", "c")))
        .price(BigDecimal.valueOf(42.00))
        .title("Title 3")
        .build();

    BatchWriteResult batchWriteResult = DependencyFactory.enhancedClient()
        .batchWriteItem(b -> b.writeBatches(
            WriteBatch.builder(ProductCatalog.class)
                .mappedTableResource(productCatalog)
                .addPutItem(prod).addPutItem(prod2).addPutItem(prod3)
                .build()
        ));
    logger.info("Unprocessed items: " +
batchWriteResult.unprocessedPutItemsForTable(productCatalog).size());
}
```

Work with immutable data classes

The mapping feature of the DynamoDB Enhanced Client API works with immutable data classes. An immutable class has only getters and requires a builder class that the SDK uses to create instances of the class. Instead of using the `@DynamoDbBean` annotation as shown in the [Customer class](#),

immutable classes use the `@DynamoDbImmutable` annotation, which takes a parameter that indicates the builder class to use.

The following class is an immutable version of `Customer`.

```
package org.example.tests.model.immutable;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbImmutable;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondarySortKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;

import java.time.Instant;

@DynamoDbImmutable(builder = CustomerImmutable.Builder.class)
public class CustomerImmutable {
    private final String id;
    private final String name;
    private final String email;
    private final Instant regDate;

    private CustomerImmutable(Builder b) {
        this.id = b.id;
        this.email = b.email;
        this.name = b.name;
        this.regDate = b.regDate;
    }

    // This method will be automatically discovered and used by the TableSchema.
    public static Builder builder() { return new Builder(); }

    @DynamoDbPartitionKey
    public String id() { return this.id; }

    @DynamoDbSortKey
    public String email() { return this.email; }

    @DynamoDbSecondaryPartitionKey(indexNames = "customers_by_name")
    public String name() { return this.name; }
```

```
@DynamoDbSecondarySortKey(indexNames = {"customers_by_date", "customers_by_name"})
public Instant regDate() { return this.regDate; }

public static final class Builder {
    private String id;
    private String email;
    private String name;
    private Instant regDate;

    // The private Builder constructor is visible to the enclosing
    CustomerImmutable class.
    private Builder() {}

    public Builder id(String id) { this.id = id; return this; }
    public Builder email(String email) { this.email = email; return this; }
    public Builder name(String name) { this.name = name; return this; }
    public Builder regDate(Instant regDate) { this.regDate = regDate; return
this; }

    // This method will be automatically discovered and used by the TableSchema.
    public CustomerImmutable build() { return new CustomerImmutable(this); }
}
}
```

You must meet the following requirements when you annotate a data class with `@DynamoDbImmutable`.

1. Every method that is both not an override of `Object.class` and has not been annotated with `@DynamoDbIgnore` must be a getter for an attribute of the DynamoDB table.
2. Every getter must have a corresponding case-sensitive setter on the builder class.
3. Only one of the following construction conditions must be met.
 - The builder class must have a public default constructor.
 - The data class must have a public static method named `builder()` that takes no parameters and returns an instance of the builder class. This option is shown in the immutable `Customer` class.
4. The builder class must have a public method named `build()` that takes no parameters and returns an instance of the immutable class.

To create a `TableSchema` for your immutable class, use the `fromImmutableClass()` method on `TableSchema` as shown in the following snippet.

```
static final TableSchema<CustomerImmutable> customerImmutableTableSchema =
    TableSchema.fromImmutableClass(CustomerImmutable.class);
```

Just as you can create a DynamoDB table from a mutable class, you can create one from an immutable class with a *one-time* call to `createTable()` of `DynamoDbTable` as shown in the following snippet example.

```
static void createTableFromImmutable(DynamoDbEnhancedClient enhancedClient, String
    tableName, DynamoDbWaiter waiter){
    // First, create an in-memory representation of the table using the 'table()'
    method of the DynamoDb Enhanced Client.
    // 'table()' accepts a name for the table and a TableSchema instance that you
    created previously.
    DynamoDbTable<CustomerImmutable> customerDynamoDbTable = enhancedClient
        .table(tableName, TableSchema.fromImmutableClass(CustomerImmutable.class));

    // Second, call the 'createTable()' method on the DynamoDbTable instance.
    customerDynamoDbTable.createTable();
    waiter.waitUntilTableExists(b -> b.tableName(tableName));
}
```

Use third-party libraries, such as Lombok

Third-party libraries, such as [Project Lombok](#), help generate boilerplate code associated with immutable objects. The DynamoDB Enhanced Client API works with these libraries as long as the data classes follow the conventions detailed in this section.

The following example shows the immutable `CustomerImmutable` class with Lombok annotations. Note how Lombok's `onMethod` feature copies attribute-based DynamoDB annotations, such as `@DynamoDbPartitionKey`, onto the generated code.

```
@Value
@Builder
@dynamoDbImmutable(builder = Customer.CustomerBuilder.class)
public class Customer {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;
```

```
@Getter(onMethod_=@DynamoDbSortKey)
private String email;

@Getter(onMethod_=@DynamoDbSecondaryPartitionKey(indexNames = "customers_by_name"))
private String name;

@Getter(onMethod_=@DynamoDbSecondarySortKey(indexNames = {"customers_by_date",
"customers_by_name"}))
private Instant createdAt;
}
```

Use expressions and conditions

Expressions in the DynamoDB Enhanced Client API are Java representations of [DynamoDB expressions](#).

The DynamoDB Enhanced Client API uses three types of expressions:

[Expression](#)

The Expression class is used when you define conditions and filters.

[QueryConditional](#)

This type of expression represents [key conditions](#) for query operations.

[UpdateExpression](#)

This class helps you write DynamoDB [update expressions](#) and is currently used in the extension framework when you update an item.

Expression anatomy

An expression is made up of the following:

- A string expression (required). The string contains a DynamoDB logic expression with placeholder names for attribute names and attribute values.
- A map of expression values (usually required).
- A map of expression names (optional).

Use a builder to generate anExpression object that takes the following general form.

```
Expression expression = Expression.builder()
    .expression(<String>)
    .expressionNames(<Map>)
    .expressionValues(<Map>)
    .build()
```

Expressions usually require a map of expression values. The map provides the values for the placeholders in the string expression. The map key consists of the placeholder name preceded with a colon (:) and the map value is an instance of [AttributeValue](#). The [AttributeValues](#) class has convenience methods to generate an `AttributeValue` instance from a literal. Alternatively, you can use the `AttributeValue.Builder` to generate an `AttributeValue` instance.

The following snippet shows a map with two entries after comment line 2. The string passed to the `expression()` method, shown after comment line 1, contains the placeholders that DynamoDB resolves before performing the operation. This snippet doesn't contain a map of expression names, because *price* is a permissible attribute name.

```
public static void scanAsync(DynamoDbAsyncTable productCatalog) {
    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
        .attributesToProject("id", "title", "authors", "price")
        .filterExpression(Expression.builder()
            // 1. :min_value and :max_value are placeholders for the values
provided by the map
            .expression("price >= :min_value AND price <= :max_value")
            // 2. Two values are needed for the expression and each is
supplied as a map entry.
            .expressionValues(
                Map.of( ":min_value", numberValue(8.00),
                    ":max_value", numberValue(400_000.00)))
            .build())
        .build();
}
```

If an attribute name in the DynamoDB table is a reserved word, begins with a number, or contains a space, a map of expression names is required for the Expression.

For example, if the attribute name was *1price* instead of *price* in the previous code example, the example would need to be modified as shown in the following example.

```
ScanEnhancedRequest request = ScanEnhancedRequest.builder()
```

```
.filterExpression(Expression.builder()
    .expression("#price >= :min_value AND #price <= :max_value")
    .expressionNames( Map.of("#price", "price") )
    .expressionValues(
        Map.of(":min_value", numberValue(8.00),
            ":max_value", numberValue(400_000.00)))
    .build())
.build();
```

A placeholder for an expression name begins with the pound sign (#). An entry for the map of expression names uses the placeholder as the key and the attribute name as the value. The map is added to the expression builder with the `expressionNames()` method. DynamoDB resolves the attribute name before it performs the operation.

Expression values are not required if a function is used in the string expression. An example of an expression function is `attribute_exists(<attribute_name>)`.

The following example builds an `Expression` that uses a [DynamoDB function](#). The expression string in this example uses no placeholders. This expression could be used on a `putItem` operation to check if an item already exists in the database with a `movie` attribute's value equal to the data object's `movie` attribute.

```
Expression exp = Expression.builder().expression("attribute_not_exists
(movie)").build();
```

The DynamoDB Developer Guide contains complete information on the [low-level expressions](#) that are used with DynamoDB.

Condition expressions and conditionals

When you use the `putItem()`, `updateItem()`, and `deleteItem()` methods, and also when you use transaction and batch operations, you use [Expression](#) objects to specify conditions that DynamoDB must meet to proceed with the operation. These expressions are named condition expressions. For an example, see the condition expression used in the `addDeleteItem()` method (after comment line 1) of [transaction example](#) shown in this guide.

When you work with the `query()` methods, a condition is expressed as a [QueryConditional](#). The `QueryConditional` class has several static convenience methods that help you write the criteria that determine which items to read from DynamoDB.

For examples of `QueryConditionals`, see the first code example of the [the section called “Query method examples”](#) section of this guide.

Filter expressions

Filter expressions are used in scan and query operations to filter the items that are returned.

A filter expression is applied after all the data is read from the database, so the read cost is the same as if there were no filter. The *Amazon DynamoDB Developer Guide* has more information about using filter expressions for both [query](#) and [scan](#) operations.

The following example shows a filter expression added to a scan request. The criteria restricts the items returned to items with a price between 8.00 and 80.00 inclusive.

```
Map<String, AttributeValue> expressionValues = Map.of(
    ":min_value", numberValue(8.00),
    ":max_value", numberValue(80.00));

ScanEnhancedRequest request = ScanEnhancedRequest.builder()
    .consistentRead(true)
    // 1. the 'attributesToProject()' method allows you to specify which
values you want returned.
    .attributesToProject("id", "title", "authors", "price")
    // 2. Filter expression limits the items returned that match the
provided criteria.
    .filterExpression(Expression.builder()
        .expression("price >= :min_value AND price <= :max_value")
        .expressionValues(expressionValues)
        .build())
    .build();
```

Update expressions

The DynamoDB Enhanced Client's `updateItem()` method provides a standard way to update items in DynamoDB. However, when you require more functionality, [UpdateExpressions](#) provide a type-safe representation of DynamoDB [update expression syntax](#). For example, you can use `UpdateExpressions` to increase values without first reading items from DynamoDB, or add individual members to a list. Update expressions are currently available in custom extensions for the `updateItem()` method.

For an example that uses update expressions, see the [custom extension example](#) in this guide.

More information about update expressions is available in the [Amazon DynamoDB Developer Guide](#).

Work with paginated results: scans and queries

The scan, query and batch methods of the DynamoDB Enhanced Client API return responses with one or more *pages*. A page contains one or more items. Your code can process the response on per-page basis or it can process individual items.

A paginated response returned by the synchronous `DynamoDbEnhancedClient` client returns a [PageIterable](#) object, whereas a response returned by the asynchronous `DynamoDbEnhancedAsyncClient` returns a [PagePublisher](#) object.

This section looks at processing paginated results and provides examples that use the scan and query APIs.

Scan a table

The SDK's [scan](#) method corresponds to the [DynamoDB operation](#) of the same name. The DynamoDB Enhanced Client API offers the same options but it uses a familiar object model and handles the pagination for you.

First, we explore the `PageIterable` interface by looking at the scan method of the synchronous mapping class, [DynamoDbTable](#).

Use the synchronous API

The following example shows the scan method that uses an [expression](#) to filter the items that are returned. The [ProductCatalog](#) is the model object that was shown earlier.

The filtering expression shown after comment line 2 limits the `ProductCatalog` items that are returned to those with a price value between 8.00 and 80.00 inclusively.

This example also excludes the `isbn` values by using the `attributesToProject` method shown after comment line 1.

After comment line 3, the `PageIterable` object, `pagedResults`, is returned by the scan method. The `stream` method of `PageIterable` returns a [java.util.Stream](#) object, which you can use to process the pages. In this example, the number of pages is counted and logged.

Starting with comment line 4, the example shows two variations of accessing the `ProductCatalog` items. The version after comment line 4a streams through each page and sorts

and logs the items on each page. The version after comment line 4b skips the page iteration and accesses the items directly.

The `PageIterable` interface offers multiple ways to process results because of its two parent interfaces—[java.lang.Iterable](#) and [SdkIterable](#). `Iterable` brings the `forEach`, `iterator` and `splitter` methods, and `SdkIterable` brings the `stream` method.

```
public static void scanSync(DynamoDbTable<ProductCatalog> productCatalog) {

    Map<String, AttributeValue> expressionValues = Map.of(
        ":min_value", numberValue(8.00),
        ":max_value", numberValue(80.00));

    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
        // 1. the 'attributesToProject()' method allows you to specify which
values you want returned.
        .attributesToProject("id", "title", "authors", "price")
        // 2. Filter expression limits the items returned that match the
provided criteria.
        .filterExpression(Expression.builder()
            .expression("price >= :min_value AND price <= :max_value")
            .expressionValues(expressionValues)
            .build())
        .build();

    // 3. A PageIterable object is returned by the scan method.
    PageIterable<ProductCatalog> pagedResults = productCatalog.scan(request);
    logger.info("page count: {}", pagedResults.stream().count());

    // 4. Log the returned ProductCatalog items using two variations.
    // 4a. This version sorts and logs the items of each page.
    pagedResults.stream().forEach(p -> p.items().stream()
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(
            item -> logger.info(item.toString())
        ));
    // 4b. This version sorts and logs all items for all pages.
    pagedResults.items().stream()
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(
            item -> logger.info(item.toString())
        );
}
```

```
}
```

Use the asynchronous API

The asynchronous scan method returns results as a `PagePublisher` object. The `PagePublisher` interface has two subscribe methods that you can use to process response pages. One subscribe method comes from the `org.reactivestreams.Publisher` parent interface. To process pages using this first option, pass a [Subscriber](#) instance to the subscribe method. The first example that follows shows the use of subscribe method.

The second subscribe method comes from the [SdkPublisher](#) interface. This version of subscribe accepts a [Consumer](#) rather than a `Subscriber`. This subscribe method variation is shown in the second example that follows.

The following example shows the asynchronous version of the scan method that uses the same filter expression shown in the previous example.

After comment line 3, `DynamoDbAsyncTable.scan` returns a `PagePublisher` object. On the next line, the code creates an instance of the `org.reactivestreams.Subscriber` interface, `ProductCatalogSubscriber`, which subscribes to the `PagePublisher` after comment line 4.

The `Subscriber` object collects the `ProductCatalog` items from each page in the `onNext` method after comment line 8 in the `ProductCatalogSubscriber` class example. The items are stored in the private `List` variable and are accessed in the calling code with the `ProductCatalogSubscriber.getSubscribedItems()` method. This is called after comment line 5.

After the list is retrieved, the code sorts all `ProductCatalog` items by price and logs each item.

The [CountDownLatch](#) in the `ProductCatalogSubscriber` class blocks the calling thread until all items have been added to the list before continuing after comment line 5.

```
public static void scanAsync(DynamoDbAsyncTable productCatalog) {
    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
        .attributesToProject("id", "title", "authors", "price")
        .filterExpression(Expression.builder()
            // 1. :min_value and :max_value are placeholders for the values
provided by the map
            .expression("price >= :min_value AND price <= :max_value")
```

```

        // 2. Two values are needed for the expression and each is
        // supplied as a map entry.
        .expressionValues(
            Map.of( ":min_value", numberValue(8.00),
                  ":max_value", numberValue(400_000.00)))
        .build())
    .build();

    // 3. A PagePublisher object is returned by the scan method.
    PagePublisher<ProductCatalog> pagePublisher = productCatalog.scan(request);
    ProductCatalogSubscriber subscriber = new ProductCatalogSubscriber();
    // 4. Subscribe the ProductCatalogSubscriber to the PagePublisher.
    pagePublisher.subscribe(subscriber);
    // 5. Retrieve all collected ProductCatalog items accumulated by the
    // subscriber.
    subscriber.getSubscribedItems().stream()
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(item ->
            logger.info(item.toString()));
    // 6. Use a Consumer to work through each page.
    pagePublisher.subscribe(page -> page
        .items().stream()
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(item ->
            logger.info(item.toString())))
        .join(); // If needed, blocks the subscribe() method thread until it is
    // finished processing.
    // 7. Use a Consumer to work through each ProductCatalog item.
    pagePublisher.items()
        .subscribe(product -> logger.info(product.toString()))
        .exceptionally(failure -> {
            logger.error("ERROR - ", failure);
            return null;
        })
        .join(); // If needed, blocks the subscribe() method thread until it is
    // finished processing.
}

```

```

private static class ProductCatalogSubscriber implements
Subscriber<Page<ProductCatalog>> {
    private CountDownLatch latch = new CountDownLatch(1);
    private Subscription subscription;
    private List<ProductCatalog> itemsFromAllPages = new ArrayList<>();
}

```

```

@Override
public void onSubscribe(Subscription sub) {
    subscription = sub;
    subscription.request(1L);
    try {
        latch.await(); // Called by main thread blocking it until latch is
released.
    } catch (InterruptedException e) {
        throw new RuntimeException(e);
    }
}

@Override
public void onNext(Page<ProductCatalog> productCatalogPage) {
    // 8. Collect all the ProductCatalog instances in the page, then ask the
publisher for one more page.
    itemsFromAllPages.addAll(productCatalogPage.items());
    subscription.request(1L);
}

@Override
public void onError(Throwable throwable) {
}

@Override
public void onComplete() {
    latch.countDown(); // Call by subscription thread; latch releases.
}

List<ProductCatalog> getSubscribedItems() {
    return this.itemsFromAllPages;
}
}

```

The following snippet example uses the version of the `PagePublisher.subscribe` method that accepts a `Consumer` after comment line 6. The Java lambda parameter consumes pages, which further process each item. In this example, each page is processed and the items on each page are sorted and then logged.

```

// 6. Use a Consumer to work through each page.
pagePublisher.subscribe(page -> page
    .items().stream()

```

```
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(item ->
            logger.info(item.toString()))
    .join(); // If needed, blocks the subscribe() method thread until it is
finished processing.
```

The `items` method of `PagePublisher` unwraps the model instances so that your code can process the items directly. This approach is shown in the following snippet.

```
// 7. Use a Consumer to work through each ProductCatalog item.
pagePublisher.items()
    .subscribe(product -> logger.info(product.toString()))
    .exceptionally(failure -> {
        logger.error("ERROR - ", failure);
        return null;
    })
    .join(); // If needed, blocks the subscribe() method thread until it is
finished processing.
```

Query a table

The [`query\(\)`](#) method of the `DynamoDbTable` class finds items based on primary key values. The `@DynamoDbPartitionKey` annotation and the optional `@DynamoDbSortKey` annotation are used to define the primary key on your data class.

The `query()` method requires a partition key value that finds items that match the supplied value. If your table also defines a sort key, you can add a value for it to your query as an additional comparison condition to fine tune the results.

Except for processing the results, the synchronous and asynchronous versions of `query()` work the same. As with the `scan` API, the `query` API returns a `PageIterable` for a synchronous call and a `PagePublisher` for asynchronous call. We discussed the use of `PageIterable` and `PagePublisher` previously in the `scan` section.

Query method examples

The `query()` method code example that follows uses the `MovieActor` class. The data class defines a composite primary key that is made up of the `movie` attribute for the partition key and the `actor` attribute for the sort key.

The class also signals that it uses a global secondary index named `acting_award_year`. The index's composite primary key is composed of the `actingaward` attribute for the partition key and

the **actingyear** for the sort key. Later in this topic, when we show how to create and use indexes, we'll refer to the **acting_award_year** index.

MovieActor class

```
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbAttribute;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondarySortKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;

import java.util.Objects;

@DynamoDbBean
public class MovieActor implements Comparable<MovieActor> {

    private String movieName;

MovieActor{movieName='movie03', actorName='actor3', actingAward='actingaward3',
  actingYear=2003, actingSchoolName='null'}
MovieActor{movieName='movie03', actorName='actor4', actingAward='actingaward4',
  actingYear=2003, actingSchoolName='actingschool4'}

```

The following code defines two [QueryConditional](#) instances. QueryConditionals work with key values—either the partition key alone or in combination with the sort key—and correspond to the [key conditional expressions](#) of the DynamoDB service API. After comment line 1, the example defines the `keyEqual` instance that matches items with a partition value of `movie01`.

This example also defines a filter expression that filters off any item that has no `actingschoolname` on after comment line 2.

After comment line 3, the example shows the [QueryEnhancedRequest](#) instance that the code passes to the `DynamoDbTable.query()` method. This object combines the key condition and filter that the SDK uses to generate the request to the DynamoDB service.

```

public static void query(DynamoDbTable movieActorTable) {

    // 1. Define a QueryConditional instance to return items matching a partition
    value.
    QueryConditional keyEqual = QueryConditional.keyEqualTo(b ->
b.partitionValue("movie01"));
    // 1a. Define a QueryConditional that adds a sort key criteria to the partition
    value criteria.

```

```

    QueryConditional sortGreaterThanOrEqualTo =
QueryConditional.sortGreaterThanOrEqualTo(b ->
b.partitionValue("movie01").sortValue("actor2"));
    // 2. Define a filter expression that filters out items whose attribute value
is null.
    final Expression filterOutNoActingschoolname =
Expression.builder().expression("attribute_exists(actingschoolname)").build();

    // 3. Build the query request.
QueryEnhancedRequest tableQuery = QueryEnhancedRequest.builder()
    .queryConditional(keyEqual)
    .filterExpression(filterOutNoActingschoolname)
    .build();
    // 4. Perform the query.
PageIterable<MovieActor> pagedResults = movieActorTable.query(tableQuery);
logger.info("page count: {}", pagedResults.stream().count()); // Log number of
pages.

pagedResults.items().stream()
    .sorted()
    .forEach(
        item -> logger.info(item.toString()) // Log the sorted list of
items.
    );

```

The following is the output from running the method. The output displays items with a `movieName` value of **movie01** and displays no items with `actingSchoolName` equal to **null**.

```

MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4',
actingYear=2001, actingSchoolName='actingschool4'}

```

In the following query request variation shown previously after comment line 3, the code replaces the `keyEqual QueryConditional` with the `sortGreaterThanOrEqualTo QueryConditional` that was defined after comment line 1a. The following code also removes the filter expression.

```
QueryEnhancedRequest tableQuery = QueryEnhancedRequest.builder()
    .queryConditional(sortGreaterThanOrEqualTo)
```

Because this table has a composite primary key, all `QueryConditional` instances require a partition key value. `QueryConditional` methods that begin with `sort...` indicate that a *sort* key is required. The results are not sorted.

The following output displays the results from the query. The query returns items that have a `movieName` value equal to **movie01** and only items that have an `actorName` value that is greater than or equal to **actor2**. Because the filter was removed, the query returns items that have no value for the `actingSchoolName` attribute.

```

Perform batch operations

The DynamoDB Enhanced Client API offers two batch methods, [batchGetItem\(\)](#) and [batchWriteItem\(\)](#).

`batchGetItem()` example

With the [DynamoDbEnhancedClient.batchGetItem\(\)](#) method, you can retrieve up to 100 individual items across multiple tables in one overall request. The following example uses the [Customer](#) and [MovieActor](#) data classes shown previously.

In the example after lines 1 and 2, you build [ReadBatch](#) objects that you later add as parameters to the `batchGetItem()` method after comment line 3.

The code after comment line 1 builds the batch to read from the `Customer` table. The code after comment line 1a shows the use of a [GetItemEnhancedRequest](#) builder that takes a primary key value and a sort key value to specify the item to read. If the data class has composite key, you must provide both the partition key value and the sort key value.

In contrast to specifying key values to request an item, you can use a data class to request an item as shown after comment line 1b. The SDK extracts the key values behind the scenes before submitting the request.

When you specify the item using the key-based approach as shown in the two statements after 2a, you can also specify that DynamoDB should perform a [strongly consistent read](#). When the `consistentRead()` method is used, it must be used on all requested items for the same table.

To retrieve the items that DynamoDB found, use the [resultsForTable\(\)](#) method that is shown after comment line 4. Call the method for each table that was read in the request. `resultsForTable()` returns a list of found items that you can process using any `java.util.List` method. This example logs each item.

To discover items that DynamoDB did not process, use the approach after comment line 5. The `BatchGetResultPage` class has the [unprocessedKeysForTable\(\)](#) method that gives you access to each key that was unprocessed. The [BatchGetItem API reference](#) has more information about situations that result in unprocessed items.

```
public static void batchGetItemExample(DynamoDbEnhancedClient enhancedClient,
                                       DynamoDbTable<Customer> customerTable,
                                       DynamoDbTable<MovieActor> movieActorTable) {

    Customer customer2 = new Customer();
    customer2.setId("2");
    customer2.setEmail("cust2@example.org");

    // 1. Build a batch to read from the Customer table.
    ReadBatch customerBatch = ReadBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        // 1a. Specify the primary key value and sort key value for the item.
        .addGetItem(b -> b.key(k ->
k.partitionValue("1").sortValue("cust1@orgname.org")))
        // 1b. Alternatively, supply a data class instances to provide the
primary key values.
        .addGetItem(customer2)
        .build();

    // 2. Build a batch to read from the MovieActor table.
    ReadBatch moveActorBatch = ReadBatch.builder(MovieActor.class)
        .mappedTableResource(movieActorTable)
        // 2a. Call consistentRead(Boolean.TRUE) for each item for the same
table.
```

```

        .addGetItem(b -> b.key(k ->
k.partitionValue("movie01").sortValue("actor1"))).consistentRead(Boolean.TRUE))
        .addGetItem(b -> b.key(k ->
k.partitionValue("movie01").sortValue("actor4"))).consistentRead(Boolean.TRUE))
        .build();

// 3. Add ReadBatch objects to the request.
BatchGetResultPageIterable resultPages = enhancedClient.batchGetItem(b ->
b.readBatches(customerBatch, moveActorBatch));

// 4. Retrieve the successfully requested items from each table.
resultPages.resultsForTable(customerTable).forEach(item ->
logger.info(item.toString()));
resultPages.resultsForTable(movieActorTable).forEach(item ->
logger.info(item.toString()));

// 5. Retrieve the keys of the items requested but not processed by the
service.
resultPages.forEach((BatchGetResultPage pageResult) -> {
    pageResult.unprocessedKeysForTable(customerTable).forEach(key ->
logger.info("Unprocessed item key: " + key.toString()));
    pageResult.unprocessedKeysForTable(movieActorTable).forEach(key ->
logger.info("Unprocessed item key: " + key.toString()));
});
}

```

Assume that the following items are in the two tables before running the example code.

Items in tables

```

Customer [id=1, name=CustName1, email=cust1@example.org,
regDate=2023-03-31T15:46:27.688Z]
Customer [id=2, name=CustName2, email=cust2@example.org,
regDate=2023-03-31T15:46:28.688Z]
Customer [id=3, name=CustName3, email=cust3@example.org,
regDate=2023-03-31T15:46:29.688Z]
Customer [id=4, name=CustName4, email=cust4@example.org,
regDate=2023-03-31T15:46:30.688Z]
Customer [id=5, name=CustName5, email=cust5@example.org,
regDate=2023-03-31T15:46:31.689Z]
MovieActor{movieName='movie01', actorName='actor0', actingAward='actingaward0',
actingYear=2001, actingSchoolName='null'}
MovieActor{movieName='movie01', actorName='actor1', actingAward='actingaward1',
actingYear=2001, actingSchoolName='actingschool1'}

```

```

MovieActor{movieName='movie01', actorName='actor2', actingAward='actingaward2',
  actingYear=2001, actingSchoolName='actingschool2'}
MovieActor{movieName='movie01', actorName='actor3', actingAward='actingaward3',
  actingYear=2001, actingSchoolName='null'}
MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4',
  actingYear=2001, actingSchoolName='actingschool4'}

```

The following output shows the items returned and logged after comment line 4.

```

Customer [id=1, name=CustName1, email=cust1@example.org,
  regDate=2023-03-31T15:46:27.688Z]
Customer [id=2, name=CustName2, email=cust2@example.org,
  regDate=2023-03-31T15:46:28.688Z]
MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4',
  actingYear=2001, actingSchoolName='actingschool4'}
MovieActor{movieName='movie01', actorName='actor1', actingAward='actingaward1',
  actingYear=2001, actingSchoolName='actingschool1'}

```

batchWriteItem() example

The `batchWriteItem()` method puts or deletes multiple items in one or more tables. You can specify up to 25 individual put or delete operations in the request. The following example uses the [ProductCatalog](#) and [MovieActor](#) model classes shown previously.

`WriteBatch` objects are built after comment lines 1 and 2. For the `ProductCatalog` table, the code puts one item and deletes one item. For the `MovieActor` table after comment line 2, the code puts two items and deletes one.

The `batchWriteItem` method is called after comment line 3. The [builder](#) parameter provides the batch requests for each table.

The returned [BatchWriteResult](#) object provides separate methods for each operation to view unprocessed requests. The code after comment line 4a provides the keys for unprocessed delete requests and the code after comment line 4b provides the unprocessed put items.

```

    public static void batchWriteItemExample(DynamoDbEnhancedClient enhancedClient,
                                             DynamoDbTable<ProductCatalog>
catalogTable,
                                             DynamoDbTable<MovieActor> movieActorTable)
    {

        // 1. Build a batch to write to the ProductCatalog table.

```

```

WriteBatch products = WriteBatch.builder(ProductCatalog.class)
    .mappedTableResource(catalogTable)
    .addPutItem(b -> b.item(getProductCatItem1()))
    .addDeleteItem(b -> b.key(k -> k
        .partitionValue(getProductCatItem2().id())
        .sortValue(getProductCatItem2().title()))))
    .build();

// 2. Build a batch to write to the MovieActor table.
WriteBatch movies = WriteBatch.builder(MovieActor.class)
    .mappedTableResource(movieActorTable)
    .addPutItem(getMovieActorYeoh())
    .addPutItem(getMovieActorBlanchettPartial())
    .addDeleteItem(b -> b.key(k -> k
        .partitionValue(getMovieActorStreep().getMovieName())
        .sortValue(getMovieActorStreep().getActorName()))))
    .build();

// 3. Add WriteBatch objects to the request.
BatchWriteResult batchWriteResult = enhancedClient.batchWriteItem(b ->
b.writeBatches(products, movies));
// 4. Retrieve keys for items the service did not process.
// 4a. 'unprocessedDeleteItemsForTable()' returns keys for delete requests that
did not process.
if (batchWriteResult.unprocessedDeleteItemsForTable(movieActorTable).size() >
0) {

batchWriteResult.unprocessedDeleteItemsForTable(movieActorTable).forEach(key ->
    logger.info(key.toString()));
}
// 4b. 'unprocessedPutItemsForTable()' returns keys for put requests that did
not process.
if (batchWriteResult.unprocessedPutItemsForTable(catalogTable).size() > 0) {
    batchWriteResult.unprocessedPutItemsForTable(catalogTable).forEach(key ->
        logger.info(key.toString()));
}
}

```

The following helper methods provide the model objects for the put and delete operations.

Helper methods

```

public static ProductCatalog getProductCatItem1() {
    return ProductCatalog.builder()

```

```
        .id(2)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(30.22))
        .title("Title 55")
        .build();
    }

    public static ProductCatalog getProductCatItem2() {
        return ProductCatalog.builder()
            .id(4)
            .price(BigDecimal.valueOf(40.00))
            .title("Title 1")
            .build();
    }

    public static MovieActor getMovieActorBlanchettPartial() {
        MovieActor movieActor = new MovieActor();
        movieActor.setActorName("Cate Blanchett");
        movieActor.setMovieName("Blue Jasmine");
        movieActor.setActingYear(2023);
        movieActor.setActingAward("Best Actress");
        return movieActor;
    }

    public static MovieActor getMovieActorStreep() {
        MovieActor movieActor = new MovieActor();
        movieActor.setActorName("Meryl Streep");
        movieActor.setMovieName("Sophie's Choice");
        movieActor.setActingYear(1982);
        movieActor.setActingAward("Best Actress");
        movieActor.setActingSchoolName("Yale School of Drama");
        return movieActor;
    }

    public static MovieActor getMovieActorYeoh(){
        MovieActor movieActor = new MovieActor();
        movieActor.setActorName("Michelle Yeoh");
        movieActor.setMovieName("Everything Everywhere All at Once");
        movieActor.setActingYear(2023);
        movieActor.setActingAward("Best Actress");
        movieActor.setActingSchoolName("Royal Academy of Dance");
        return movieActor;
    }
}
```

```
}

```

Assume that the tables contain the following items before you run the example code.

```
MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
```

After the example code finishes, the tables contain the following items.

```
MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='null'}
MovieActor{movieName='Everything Everywhere All at Once', actorName='Michelle Yeoh', actingAward='Best Actress', actingYear=2023, actingSchoolName='Royal Academy of Dance'}
ProductCatalog{id=2, title='Title 55', isbn='1-565-85698', authors=[a, b], price=30.22}
```

Notice in the `MovieActor` table that the `Blue Jasmine` movie item has been replaced with the item used in the `put` request acquired through the `getMovieActorBlanchettPartial()` helper method. If a data bean attribute value was not provided, the value in the database is removed. This is why the resulting `actingSchoolName` is null for the `Blue Jasmine` movie item.

Note

Although the API documentation suggests that condition expressions can be used and that consumed capacity and collection metrics can be returned with individual [put](#) and [delete](#) requests, this is not the case in a batch write scenario. To improve performance for batch operations, these individual options are ignored.

Perform transaction operations

The DynamoDB Enhanced Client API provides the `transactGetItems()` and the `transactWriteItems()` methods. The transaction methods of the SDK for Java provide atomicity, consistency, isolation, and durability (ACID) in DynamoDB tables, helping you to maintain data correctness in your applications.

transactGetItems() example

The [transactGetItems\(\)](#) method accepts up to 100 individual requests for items. All items are read in a single atomic transaction. The *Amazon DynamoDB Developer Guide* has information about the [conditions that cause a transactGetItems\(\) method to fail](#), and also about the isolation level used when you call [transactGetItem\(\)](#).

After comment line 1 in the following example, the code calls the `transactGetItems()` method with a [builder](#) parameter. The builder's [addGetItem\(\)](#) is invoked three times with a data object that contains the key values that the SDK will use to generate the final request.

The request returns a list of [Document](#) objects after comment line 2. The list of documents that is returned contains non-null [Document](#) instances of item data in the same order as requested. The [Document.getItem\(MappedTableResource<T> mappedTableResource\)](#) method converts an untyped Document object into a typed Java object if item data was returned, otherwise the method returns null.

```
public static void transactGetItemsExample(DynamoDbEnhancedClient enhancedClient,
                                          DynamoDbTable<ProductCatalog>
catalogTable,
                                          DynamoDbTable<MovieActor>
movieActorTable) {

    // 1. Request three items from two tables using a builder.
    final List<Document> documents = enhancedClient.transactGetItems(b -> b
        .addGetItem(catalogTable,
Key.builder().partitionValue(2).sortValue("Title 55").build())
        .addGetItem(movieActorTable, Key.builder().partitionValue("Sophie's
Choice").sortValue("Meryl Streep").build())
        .addGetItem(movieActorTable, Key.builder().partitionValue("Blue
Jasmine").sortValue("Cate Blanchett").build())
        .build());

    // 2. A list of Document objects is returned in the same order as requested.
    ProductCatalog title55 = documents.get(0).getItem(catalogTable);
    if (title55 != null) {
        logger.info(title55.toString());
    }

    MovieActor sophiesChoice = documents.get(1).getItem(movieActorTable);
    if (sophiesChoice != null) {
        logger.info(sophiesChoice.toString());
    }
}
```

```

    }

    // 3. The getItem() method returns null if the Document object contains no item
    from DynamoDB.
    MovieActor blueJasmine = documents.get(2).getItem(movieActorTable);
    if (blueJasmine != null) {
        logger.info(blueJasmine.toString());
    }
}

```

The DynamoDB tables contain the following items before the code example runs.

```

ProductCatalog{id=2, title='Title 55', isbn='orig_isbn', authors=[b, g], price=10}
MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best
Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}

```

The following output is logged. If an item is requested but not found, it not returned as is the case for the request for the movie named Blue Jasmine.

```

ProductCatalog{id=2, title='Title 55', isbn='orig_isbn', authors=[b, g], price=10}
MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best
Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}

```

transactWriteItems() examples

The [transactWriteItems\(\)](#) accepts up to 100 put, update, or delete actions in a single atomic transaction across multiple tables. The *Amazon DynamoDB Developer Guide* contains details about restrictions and failure conditions of the [underlying DynamoDB service operation](#).

Basic example

In the following example, four operations are requested for two tables. The corresponding model classes [ProductCatalog](#) and [MovieActor](#) were shown previously.

Each of the three possible operations—put, update, and delete—uses a dedicated request parameter to specify the details.

The code after comment line 1 shows the simple variation of the `addPutItem()` method. The method accepts a [MappedTableResource](#) object and the data object instance to put. The statement after comment line 2 shows the variation that accepts a

[TransactPutItemEnhancedRequest](#) instance. This variation lets you add more options in the request, such as a condition expression. A subsequent [example](#) shows a condition expression for an individual operation.

An update operation is requested after comment line 3.

[TransactUpdateItemEnhancedRequest](#) has an `ignoreNulls()` method that lets you configure what the SDK does with null values on the model object. If the `ignoreNulls()` method returns true, the SDK does not remove the table's attribute values for data object attributes that are null. If the `ignoreNulls()` method returns false, the SDK requests the DynamoDB service to remove the attributes from the item in the table. The default value for `ignoreNulls` is false.

The statement after comment line 4 shows the variation of a delete request that takes a data object. The enhanced client extracts the key values before dispatching the final request.

```
public static void transactWriteItems(DynamoDbEnhancedClient enhancedClient,
                                     DynamoDbTable<ProductCatalog> catalogTable,
                                     DynamoDbTable<MovieActor> movieActorTable) {

    enhancedClient.transactWriteItems(b -> b
        // 1. Simplest variation of put item request.
        .addPutItem(catalogTable, getProductCatId2())
        // 2. Put item request variation that accommodates condition
expressions.
        .addPutItem(movieActorTable,
TransactPutItemEnhancedRequest.builder(MovieActor.class)
            .item(getMovieActorStreep())

        .conditionExpression(Expression.builder().expression("attribute_not_exists
(movie)").build())
            .build())
        // 3. Update request that does not remove attribute values on the table
if the data object's value is null.
        .addUpdateItem(catalogTable,
TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
            .item(getProductCatId4ForUpdate())
            .ignoreNulls(Boolean.TRUE)
            .build())
        // 4. Variation of delete request that accepts a data object. The key
values are extracted for the request.
        .addDeleteItem(movieActorTable, getMovieActorBlanchett())

    );
}
```

```
}
```

The following helper methods provide the data objects for the add*Item parameters.

Helper methods

```
public static ProductCatalog getProductCatId2() {
    return ProductCatalog.builder()
        .id(2)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(30.22))
        .title("Title 55")
        .build();
}

public static ProductCatalog getProductCatId4ForUpdate() {
    return ProductCatalog.builder()
        .id(4)
        .price(BigDecimal.valueOf(40.00))
        .title("Title 1")
        .build();
}

public static MovieActor getMovieActorBlanchett() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Cate Blanchett");
    movieActor.setMovieName("Tar");
    movieActor.setActingYear(2022);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("National Institute of Dramatic Art");
    return movieActor;
}

public static MovieActor getMovieActorStreep() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Meryl Streep");
    movieActor.setMovieName("Sophie's Choice");
    movieActor.setActingYear(1982);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("Yale School of Drama");
    return movieActor;
}
```

The DynamoDB tables contain the following items before the code example runs.

```
1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Tar', actorName='Cate Blanchett', actingAward='Best Actress',
  actingYear=2022, actingSchoolName='National Institute of Dramatic Art'}
```

The following items are in the tables after the code finishes running.

```
3 | ProductCatalog{id=2, title='Title 55', isbn='1-565-85698', authors=[a, b],
  price=30.22}
4 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=40.0}
5 | MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best
  Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
```

The item on line 2 has been deleted and lines 3 and 5 show the items that were put. Line 4 shows the update of line 1. The price value is the only value that changed on the item. If `ignoreNulls()` had returned `false`, line 4 would look like the following line.

```
ProductCatalog{id=4, title='Title 1', isbn='null', authors=null, price=40.0}
```

Condition check example

The following example shows the use of a condition check. A condition check is used to check that an item exists or to check the condition of specific attributes of an item in the database. The item checked in the condition check cannot be used in another operation in the transaction.

Note

You can't target the same item with multiple operations within the same transaction. For example, you can't perform a condition check and also attempt to update the same item in the same transaction.

The example shows one of each type of operation in a transactional write items request. After comment line 2, the `addConditionCheck()` method supplies the condition that fails the transaction if the `conditionExpression` parameter evaluates to `false`. The condition expression that is returned from the method shown in the Helper methods block checks if the award year for the movie `Sophie's Choice` is not equal to 1982. If it is, the expression evaluates to `false` and the transaction fails.

This guide discusses [expressions](#) in depth in another topic.

```

public static void conditionCheckFailExample(DynamoDbEnhancedClient enhancedClient,
                                             DynamoDbTable<ProductCatalog>
catalogTable,
                                             DynamoDbTable<MovieActor>
movieActorTable) {

    try {
        enhancedClient.transactWriteItems(b -> b
            // 1. Perform one of each type of operation with the next three
methods.
                .addPutItem(catalogTable,
TransactPutItemEnhancedRequest.builder(ProductCatalog.class)
                    .item(getProductCatId2()).build())
                .addUpdateItem(catalogTable,
TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
                    .item(getProductCatId4ForUpdate())
                    .ignoreNulls(Boolean.TRUE).build())
                .addDeleteItem(movieActorTable,
TransactDeleteItemEnhancedRequest.builder()
                    .key(b1 -> b1

.partitionValue(getMovieActorBlanchett().getMovieName())

.sortValue(getMovieActorBlanchett().getActorName())).build()
            // 2. Add a condition check on a table item that is not involved in
another operation in this request.
                .addConditionCheck(movieActorTable, ConditionCheck.builder()
                    .conditionExpression(buildConditionCheckExpression())
                    .key(k -> k
                        .partitionValue("Sophie's Choice")
                        .sortValue("Meryl Streep"))
            // 3. Specify the request to return existing values from
the item if the condition evaluates to true.
                .returnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD)
                    .build())
                .build());
            // 4. Catch the exception if the transaction fails and log the information.
        } catch (TransactionCanceledException ex) {
            ex.cancellationReasons().stream().forEach(cancellationReason -> {
                logger.info(cancellationReason.toString());
            });
        }
    }
}

```

```
    }  
}
```

The following helper methods are used in the previous code example.

Helper methods

```
private static Expression buildConditionCheckExpression() {  
    Map<String, AttributeValue> expressionValue = Map.of(  
        ":year", numberValue(1982));  
  
    return Expression.builder()  
        .expression("actingyear <> :year")  
        .expressionValues(expressionValue)  
        .build();  
}  
  
public static ProductCatalog getProductCatId2() {  
    return ProductCatalog.builder()  
        .id(2)  
        .isbn("1-565-85698")  
        .authors(new HashSet<>(Arrays.asList("a", "b")))  
        .price(BigDecimal.valueOf(30.22))  
        .title("Title 55")  
        .build();  
}  
  
public static ProductCatalog getProductCatId4ForUpdate() {  
    return ProductCatalog.builder()  
        .id(4)  
        .price(BigDecimal.valueOf(40.00))  
        .title("Title 1")  
        .build();  
}  
  
public static MovieActor getMovieActorBlanchett() {  
    MovieActor movieActor = new MovieActor();  
    movieActor.setActorName("Cate Blanchett");  
    movieActor.setMovieName("Blue Jasmine");  
    movieActor.setActingYear(2013);  
    movieActor.setActingAward("Best Actress");  
    movieActor.setActingSchoolName("National Institute of Dramatic Art");  
    return movieActor;  
}
```

```
}

```

The DynamoDB tables contain the following items before the code example runs.

```
1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
3 | MovieActor{movieName='Tar', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2022, actingSchoolName='National Institute of Dramatic Art'}
```

The following items are in the tables after the code finishes running.

```
ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
MovieActor{movieName='Tar', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2022, actingSchoolName='National Institute of Dramatic Art'}
```

Items remain unchanged in the tables because the transaction failed. The `actingYear` value for the movie `Sophie's Choice` is 1982, as shown on line 2 of the items in the table before the `transactWriteItem()` method is called.

To capture the cancellation information for the transaction, enclose the `transactWriteItems()` method call in a try block and catch the [TransactionCanceledException](#). After comment line 4 of the example, the code logs each [CancellationReason](#) object. Because the code following comment line 3 of the example specifies that values should be returned for the item that caused the transaction to fail, the log displays the raw database values for the `Sophie's Choice` movie item.

```
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Item={actor=AttributeValue(S=Meryl Streep),
  movie=AttributeValue(S=Sophie's Choice), actingaward=AttributeValue(S=Best Actress),
  actingyear=AttributeValue(N=1982), actingschoolname=AttributeValue(S=Yale School of Drama)},
  Code=ConditionalCheckFailed, Message=The conditional request failed.)
```

Single operation condition example

The following example shows the use of a condition on a single operation in a transaction request. The delete operation after comment line 1 contains a condition that checks the value of the target item of the operation against the database. In this example, the condition expression created with the helper method after comment line 2 specifies that the item should be deleted from the database if the acting year of the movie is not equal to 2013.

[Expressions](#) are discussed later in this guide.

```

public static void singleOperationConditionFailExample(DynamoDbEnhancedClient
enhancedClient,

DynamoDbTable<ProductCatalog> catalogTable,
                                                    DynamoDbTable<MovieActor>
movieActorTable) {
    try {
        enhancedClient.transactWriteItems(b -> b
            .addPutItem(catalogTable,
TransactPutItemEnhancedRequest.builder(ProductCatalog.class)
                .item(getProductCatId2())
                .build())
            .addUpdateItem(catalogTable,
TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
                .item(getProductCatId4ForUpdate())
                .ignoreNulls(Boolean.TRUE).build())
            // 1. Delete operation that contains a condition expression
            .addDeleteItem(movieActorTable,
TransactDeleteItemEnhancedRequest.builder()
                .key((Key.Builder k) -> {
                    MovieActor blanchett = getMovieActorBlanchett();
                    k.partitionValue(blanchett.getMovieName())
                        .sortValue(blanchett.getActorName());
                })
                .conditionExpression(buildDeleteItemExpression()))
        .returnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD)
            .build())
        .build());
    } catch (TransactionCanceledException ex) {
        ex.cancellationReasons().forEach(cancellationReason ->
logger.info(cancellationReason.toString()));
    }
}

```

```
}

// 2. Provide condition expression to check if 'actingyear' is not equal to 2013.
private static Expression buildDeleteItemExpression() {
    Map<String, AttributeValue> expressionValue = Map.of(
        ":year", numberValue(2013));

    return Expression.builder()
        .expression("actingyear <> :year")
        .expressionValues(expressionValue)
        .build();
}
```

The following helper methods are used in the previous code example.

Helper methods

```
public static ProductCatalog getProductCatId2() {
    return ProductCatalog.builder()
        .id(2)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(30.22))
        .title("Title 55")
        .build();
}

public static ProductCatalog getProductCatId4ForUpdate() {
    return ProductCatalog.builder()
        .id(4)
        .price(BigDecimal.valueOf(40.00))
        .title("Title 1")
        .build();
}

public static MovieActor getMovieActorBlanchett() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Cate Blanchett");
    movieActor.setMovieName("Blue Jasmine");
    movieActor.setActingYear(2013);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("National Institute of Dramatic Art");
    return movieActor;
}
```

The DynamoDB tables contain the following items before the code example runs.

```
1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
```

The following items are in the tables after the code finishes running.

```
ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2023-03-15 11:29:07 [main] INFO org.example.tests.TransactDemoTest:168 -
MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
```

Items remain unchanged in the tables because the transaction failed. The `actingYear` value for the movie `Blue Jasmine` is `2013` as shown on line 2 in the list of items before the code example runs.

The following lines are logged to the console.

```
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Item={actor=AttributeValue(S=Cate Blanchett),
movie=AttributeValue(S=Blue Jasmine), actingaward=AttributeValue(S=Best Actress),
actingyear=AttributeValue(N=2013), actingschoolname=AttributeValue(S=National
Institute of Dramatic Art)},
Code=ConditionalCheckFailed, Message=The conditional request failed)
```

Use secondary indices

Secondary indices improve data access by defining alternative keys that you use in query and scan operations. Global secondary indices (GSI) have a partition key and a sort key that can be different from those on the base table. In contrast, local secondary indices (LSI) use the partition key of the primary index.

Annotate data class with secondary index annotations

Attributes that participate in secondary indices require either the `@DynamoDbSecondaryPartitionKey` or `@DynamoDbSecondarySortKey` annotation.

The following class shows annotations for two indices. The GSI named `SubjectLastPostedDateIndex` uses the `Subject` attribute for the partition key and the `LastPostedDateTime` for the sort

key. The LSI named *ForumLastPostedDateIndex* uses the `ForumName` as its partition key and `LastPostedDateTime` as its sort key.

Note that the `Subject` attribute serves a dual role. It is the primary key's sort key and the partition key of the GSI named *SubjectLastPostedDateIndex*.

MessageThread class

The `MessageThread` class is suitable to use as a data class for the [example Thread table](#) in the *Amazon DynamoDB Developer Guide*.

Imports

```
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import
    software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondarySortKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;

import java.util.List;
```

```
@DynamoDbBean

        ", Subject='" + Subject + '\'' +
        ", Message='" + Message + '\'' +
        ", LastPostedBy='" + LastPostedBy + '\'' +
        ", LastPostedDateTime='" + LastPostedDateTime + '\'' +
        ", Views=" + Views +
        ", Replies=" + Replies +
        ", Answered=" + Answered +
        ", Tags=" + Tags +
        '}';
    }
}

```

Create the index

Beginning with version 2.20.86 of the SDK for Java, the `createTable()` method automatically generates secondary indexes from data class annotations. By default, all attributes from the base table are copied to an index and the provisioned throughput values are 20 read capacity units and 20 write capacity units.

However, if you use an SDK version prior to 2.20.86, you need to build the index along with the table as shown in the following example. This example builds the two indexes for the `Thread` table. The [builder](#) parameter has methods to configure both types of indexes as shown after comment lines 1 and 2. You use the index builder's `indexName()` method to associate the index names specified in the data class annotations with the intended type of index.

This code configures all of the table attributes to end up in both indexes after comment lines 3 and 4. More information about [attribute projections](#) is available in the *Amazon DynamoDB Developer Guide*.

```

public static void createMessageThreadTable(DynamoDbTable<MessageThread>
messageThreadDynamoDbTable, DynamoDbClient dynamoDbClient) {
    messageThreadDynamoDbTable.createTable(b -> b
        // 1. Generate the GSI.
        .globalSecondaryIndices(gsi ->
gsi.indexName("SubjectLastPostedDateIndex")
        // 3. Populate the GSI with all attributes.
        .projection(p -> p
            .projectionType(ProjectionType.ALL))
        )
        // 2. Generate the LSI.
        .localSecondaryIndices(lsi -> lsi.indexName("ForumLastPostedDateIndex"))
    )
}

```

```

        // 4. Populate the LSI with all attributes.
        .projection(p -> p
            .projectionType(ProjectionType.ALL))
    )
};

```

Query by using an index

The following example queries the local secondary index *ForumLastPostedDateIndex*.

Following comment line 2, you create a [QueryConditional](#) object that is required when calling the [DynamoDbIndex.query\(\)](#) method.

You get a reference to the index you want to query after comment line 3 by passing in the name of the index. Following comment line 4, you call the `query()` method on the index passing in the `QueryConditional` object.

You also configure the query to return three attribute values as shown after comment line 5. If `attributesToProject()` is not called, the query returns all attribute values. Notice that the specified attribute names begin with lowercase letters. These attribute names match those used in the table, not necessarily the attribute names of the data class.

Following comment line 6, iterate through the results and log each item returned by the query and also store it in the list to return to the caller.

```

public static List<MessageThread> queryUsingSecondaryIndices(DynamoDbEnhancedClient
    enhancedClient,
                                                            String lastPostedDate,
                                                            DynamoDbTable<MessageThread> threadTable) {
    // 1. Log the parameter value.
    logger.info("lastPostedDate value: {}", lastPostedDate);

    // 2. Create a QueryConditional whose sort key value must be greater than or
    equal to the parameter value.
    QueryConditional queryConditional =
    QueryConditional.sortGreaterThanOrEqualTo(qc ->
        qc.partitionValue("Forum02").sortValue(lastPostedDate));

    // 3. Specify the index name to query the DynamoDbIndex instance.
    final DynamoDbIndex<MessageThread> forumLastPostedDateIndex =
    threadTable.index("ForumLastPostedDateIndex");

```

```

    // 4. Perform the query by using the QueryConditional object.
    final SdkIterable<Page<MessageThread>> pagedResult =
forumLastPostedDateIndex.query(q -> q
        .queryConditional(queryConditional)
        // 5. Request three attribute in the results.
        .attributesToProject("forumName", "subject", "lastPostedDateTime"));

    List<MessageThread> collectedItems = new ArrayList<>();
    // 6. Iterate through the pages response and sort the items.
    pagedResult.stream().forEach(page -> page.items().stream()

        .sorted(Comparator.comparing(MessageThread::getLastPostedDateTime))
            .forEach(mt -> {
                // 7. Log the returned items and add the collection to
return to the caller.
                logger.info(mt.toString());
                collectedItems.add(mt);
            }));
    return collectedItems;
}

```

The following items exist in the database before the query is run.

```

MessageThread{ForumName='Forum01', Subject='Subject01', Message='Message01',
  LastPostedBy='', LastPostedDateTime='2023.03.28', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject02', Message='Message02',
  LastPostedBy='', LastPostedDateTime='2023.03.29', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject04', Message='Message04',
  LastPostedBy='', LastPostedDateTime='2023.03.31', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject08', Message='Message08',
  LastPostedBy='', LastPostedDateTime='2023.04.04', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject10', Message='Message10',
  LastPostedBy='', LastPostedDateTime='2023.04.06', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum03', Subject='Subject03', Message='Message03',
  LastPostedBy='', LastPostedDateTime='2023.03.30', Views=0, Replies=0, Answered=0,
  Tags=null}

```

```
MessageThread{ForumName='Forum03', Subject='Subject06', Message='Message06',
  LastPostedBy='', LastPostedDateTime='2023.04.02', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum03', Subject='Subject09', Message='Message09',
  LastPostedBy='', LastPostedDateTime='2023.04.05', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum05', Subject='Subject05', Message='Message05',
  LastPostedBy='', LastPostedDateTime='2023.04.01', Views=0, Replies=0, Answered=0,
  Tags=null}
MessageThread{ForumName='Forum07', Subject='Subject07', Message='Message07',
  LastPostedBy='', LastPostedDateTime='2023.04.03', Views=0, Replies=0, Answered=0,
  Tags=null}
```

The logging statements at lines 1 and 6 result in the following console output.

```
lastPostedDate value: 2023.03.31
MessageThread{ForumName='Forum02', Subject='Subject04', Message='', LastPostedBy='',
  LastPostedDateTime='2023.03.31', Views=0, Replies=0, Answered=0, Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject08', Message='', LastPostedBy='',
  LastPostedDateTime='2023.04.04', Views=0, Replies=0, Answered=0, Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject10', Message='', LastPostedBy='',
  LastPostedDateTime='2023.04.06', Views=0, Replies=0, Answered=0, Tags=null}
```

The query returned items with a `forumName` value of `Forum02` and a `lastPostedDateTime` value greater than or equal to `2023.03.31`. The results show message values with an empty string although the message attributes have values in the index. This is because the message attribute was not projected after comment line 5.

Use advanced mapping features

Learn about advanced table schema features in the DynamoDB Enhanced Client API.

Understand table schema types

[TableSchema](#) is the interface to the mapping functionality of the DynamoDB Enhanced Client API. It can map a data object to and from a map of [AttributeValues](#). A `TableSchema` object needs to know about the structure of the table it is mapping. This structure information is stored in a [TableMetadata](#) object.

The enhanced client API has several implementations of `TableSchema`, which follow.

Table schema generated from annotated classes

It is a moderately expensive operation to build a `TableSchema` from annotated classes, so we recommend doing this once, at application startup.

[BeanTableSchema](#)

This implementation is built based on attributes and annotations of a bean class. An example of this approach is demonstrated in the [Get started section](#).

Note

If a `BeanTableSchema` is not behaving as you expect, enable debug logging for `software.amazon.awssdk.enhanced.dynamodb.beans`.

[ImmutableTableSchema](#)

This implementation is built from an immutable data class. This approach is described in the [???](#) section.

Table schema generated with a builder

The following `TableSchemas` are built from code by using a builder. This approach is less costly than the approach that uses annotated data classes. The builder approach avoids the use of annotations and doesn't require JavaBean naming standards.

[StaticTableSchema](#)

This implementation is built for mutable data classes. The getting started section of this guide demonstrated how to [generate a `StaticTableSchema` using a builder](#).

[StaticImmutableTableSchema](#)

Similarly to how you build a `StaticTableSchema`, you generate an implementation of this type of `TableSchema` using a [builder](#) for use with immutable data classes.

Table schema for data without a fixed schema

[DocumentTableSchema](#)

Unlike other implementations of `TableSchema`, you don't define attributes for a `DocumentTableSchema` instance. Usually, you specify only primary keys and attribute converter providers. An `EnhancedDocument` instance provides the attributes that you build from individual elements or from a JSON string.

Explicitly include or exclude attributes

The DynamoDB Enhanced Client API offers annotations to exclude data class attributes from becoming attributes on a table. With the API, you can also use an attribute name that's different from the data class attribute name.

Exclude attributes

To ignore attributes that should not be mapped to a DynamoDB table, mark the attribute with the `@DynamoDbIgnore` annotation.

```
private String internalKey;

@dynamoDbIgnore
public String getInternalKey() { return this.internalKey; }
public void setInternalKey(String internalKey) { this.internalKey = internalKey;}
```

Include attributes

To change the name of an attribute used in the DynamoDB table, mark it with the `@DynamoDbAttribute` annotation and supply a different name.

```
private String internalKey;

@dynamoDbAttribute("renamedInternalKey")
public String getInternalKey() { return this.internalKey; }
public void setInternalKey(String internalKey) { this.internalKey = internalKey;}
```

Control attribute conversion

By default, a table schema provides converters for many common Java types through a default implementation of the [AttributeConverterProvider](#) interface. You can change the overall

default behavior with a custom `AttributeConverterProvider` implementation. You can also change the converter for a single attribute.

For a list of available converters, see the [AttributeConverter](#) interface Java doc.

Provide custom attribute converter providers

You can provide a single `AttributeConverterProvider` or a chain of ordered `AttributeConverterProviders` through the `@DynamoDbBean (converterProviders = {...})` annotation. Any custom `AttributeConverterProvider` must extend the `AttributeConverterProvider` interface.

Note that if you supply your own chain of attribute converter providers, you will override the default converter provider, `DefaultAttributeConverterProvider`. If you want to use the functionality of the `DefaultAttributeConverterProvider`, you must include it in the chain.

It's also possible to annotate the bean with an empty array `{}`. This disables the use of any attribute converter providers, including the default. In this case all attributes that are to be mapped must have their own attribute converter.

The following snippet shows a single converter provider.

```
@DynamoDbBean(converterProviders = ConverterProvider1.class)
public class Customer {

}
```

The following snippet shows the use of a chain of converter providers. Since the SDK default is provided last, it has the lowest priority.

```
@DynamoDbBean(converterProviders = {
    ConverterProvider1.class,
    ConverterProvider2.class,
    DefaultAttributeConverterProvider.class})
public class Customer {

}
```

The static table schema builders have an `attributeConverterProviders()` method that works the same way. This is shown in the following snippet.

```
private static final StaticTableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    StaticTableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("name")
            a.getter(Customer::getName)
            a.setter(Customer::setName))
        .attributeConverterProviders(converterProvider1, converterProvider2)
        .build();
```

Override the mapping of a single attribute

To override the way a single attribute is mapped, supply an `AttributeConverter` for the attribute. This addition overrides any converters provided by `AttributeConverterProviders` in the table schema. This adds a custom converter for only that attribute. Other attributes, even those of the same type, won't use that converter unless it is explicitly specified for those other attributes.

The `@DynamoDbConvertedBy` annotation is used to specify the custom `AttributeConverter` class as shown in the following snippet.

```
@DynamoDbBean
public class Customer {
    private String name;

    @DynamoDbConvertedBy(CustomAttributeConverter.class)
    public String getName() { return this.name; }
    public void setName(String name) { this.name = name;}
}
```

The builders for static schemas have an equivalent attribute builder `attributeConverter()` method. This method takes an instance of an `AttributeConverter` as the following shows.

```
private static final StaticTableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    StaticTableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("name")
            a.getter(Customer::getName)
            a.setter(Customer::setName)
            a.attributeConverter(customAttributeConverter))
        .build();
```

Example

This example shows an `AttributeConverterProvider` implementation that provides an attribute converter for [java.net.HttpCookie](http://java.net/HttpCookie) objects.

The following `SimpleUser` class contains an attribute named `lastUsedCookie` that is an instance of `HttpCookie`.

The parameter to the `@DynamoDbBean` annotations lists the two `AttributeConverterProvider` classes that provide converters.

Class with annotations

```
@DynamoDbBean(converterProviders = {CookieConverterProvider.class,
DefaultAttributeConverterProvider.class})
public static final class SimpleUser {
    private String name;
    private HttpCookie lastUsedCookie;

    @DynamoDbPartitionKey
    public String getName() {
        return name;
    }

    public void setName(String name) {
        this.name = name;
    }

    public HttpCookie getLastUsedCookie() {
        return lastUsedCookie;
    }

    public void setLastUsedCookie(HttpCookie lastUsedCookie) {
        this.lastUsedCookie = lastUsedCookie;
    }
}
```

Static table schema

```
private static final TableSchema<SimpleUser> SIMPLE_USER_TABLE_SCHEMA =
    TableSchema.builder(SimpleUser.class)
        .newItemSupplier(SimpleUser::new)
        .attributeConverterProviders(CookieConverterProvider.create(),
AttributeConverterProvider.defaultProvider())
```

```

        .addAttribute(String.class, a -> a.name("name")
            .setter(SimpleUser::setName)
            .getter(SimpleUser::getName)
            .tags(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(HttpCookie.class, a -> a.name("lastUsedCookie")
            .setter(SimpleUser::setLastUsedCookie)
            .getter(SimpleUser::getLastUsedCookie))
        .build();

```

The `CookieConverterProvider` in the following example provides an instance of an `HttpCookieConverter`.

```

public static final class CookieConverterProvider implements
AttributeConverterProvider {
    private final Map<EnhancedType<?>, AttributeConverter<?>> converterCache =
ImmutableMap.of(
        // 1. Add HttpCookieConverter to the internal cache.
        EnhancedType.of(HttpCookie.class), new HttpCookieConverter());

    public static CookieConverterProvider create() {
        return new CookieConverterProvider();
    }

    // The SDK calls this method to find out if the provider contains a
AttributeConverter instance
    // for the EnhancedType<T> argument.
    @SuppressWarnings("unchecked")
    @Override
    public <T> AttributeConverter<T> converterFor(EnhancedType<T> enhancedType) {
        return (AttributeConverter<T>) converterCache.get(enhancedType);
    }
}

```

Conversion code

In the `transformFrom()` method of the following `HttpCookieConverter` class, the code receives an `HttpCookie` instance and transforms it into a `DynamoDB` map that is stored as an attribute.

The `transformTo()` method receives a `DynamoDB` map parameter, then invokes the `HttpCookie` constructor that requires a name and a value.

```

public static final class HttpCookieConverter implements
AttributeConverter<HttpCookie> {

    @Override
    public AttributeValue transformFrom(HttpCookie httpCookie) {

        return AttributeValue.fromM(
            Map.of ("cookieName", AttributeValue.fromS(httpCookie.getName()),
                "cookieValue", AttributeValue.fromS(httpCookie.getValue()))
        );
    }

    @Override
    public HttpCookie transformTo(AttributeValue attributeValue) {
        Map<String, AttributeValue> map = attributeValue.m();
        return new HttpCookie(
            map.get("cookieName").s(),
            map.get("cookieValue").s());
    }

    @Override
    public EnhancedType<HttpCookie> type() {
        return EnhancedType.of(HttpCookie.class);
    }

    @Override
    public AttributeValueType attributeValueType() {
        return AttributeValueType.M;
    }
}

```

Change update behavior of attributes

You can customize the update behavior of individual attributes when you perform an *update* operation. Some examples of update operations in the DynamoDB Enhanced Client API are [updateItem\(\)](#) and [transactWriteItems\(\)](#).

For example, imagine that you want to store a *created on* timestamp on your record. However, you want its value to be written only if there's no existing value for the attribute already in the database. In this case, you use the [WRITE_IF_NOT_EXISTS](#) update behavior.

The following example shows the annotation that adds the behavior to the `createdOn` attribute.

```

@DynamoDbBean
public class Customer extends GenericRecord {
    private String id;
    private Instant createdOn;

    @DynamoDbPartitionKey
    public String getId() { return this.id; }
    public void setId(String id) { this.name = id; }

    @DynamoDbUpdateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS)
    public Instant getCreatedOn() { return this.createdOn; }
    public void setCreatedOn(Instant createdOn) { this.createdOn = createdOn; }
}

```

You can declare the same update behavior when you build a static table schema as shown in the following example after comment line 1.

```

static final TableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    TableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(Customer::getId)
            .setter(Customer::setId)

        .tags(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(Instant.class, a -> a.name("createdOn")
            .getter(Customer::getCreatedOn)
            .setter(Customer::setCreatedOn)
            // 1. Add an UpdateBehavior.

        .tags(StaticAttributeTags.updateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS)))
        .build();

```

Flatten attributes from other classes

If the attributes for your table are spread across several different Java classes, either through inheritance or composition, the DynamoDB Enhanced Client API provides support to flatten the attributes into one class.

Use inheritance

If your classes use inheritance, use the following approaches to flatten the hierarchy.

Use annotated beans

For the annotation approach, both classes must carry the `@DynamoDbBean` annotation and a class must carry one or more primary key annotations.

The following shows examples of data classes that have an inheritance relationship.

Standard data class

```
@DynamoDbBean
public class Customer extends GenericRecord {
    private String name;

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }
}

@dynamoDbBean
public abstract class GenericRecord {
    private String id;
    private String createdAt;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedAt() { return createdAt; }
    public void setCreatedAt(String createdAt) { this.createdAt =
    createdAt; }
}
```

Lombok

Lombok's [onMethod option](#) copies attribute-based DynamoDB annotations, such as `@DynamoDbPartitionKey`, onto the generated code.

```
@DynamoDbBean
@Data
@ToString(callSuper = true)
public class Customer extends GenericRecord {
    private String name;
}
```

```

@Data
@DynamoDbBean
public abstract class GenericRecord {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;
    private String createdAt;
}

```

Use static schemas

For the static schema approach, use the `extend()` method of the builder to collapse the attributes of the parent class onto the child class. This is shown after comment line 1 in the following example.

```

        StaticTableSchema<org.example.tests.model.inheritance.stat.GenericRecord>
GENERIC_RECORD_SCHEMA =

StaticTableSchema.builder(org.example.tests.model.inheritance.stat.GenericRecord.class)
    // The partition key will be inherited by the top level mapper.
    .addAttribute(String.class, a -> a.name("id"))

    .getter(org.example.tests.model.inheritance.stat.GenericRecord::getId)

    .setter(org.example.tests.model.inheritance.stat.GenericRecord::setId)
        .tags(primaryPartitionKey()))
    .addAttribute(String.class, a -> a.name("created_date"))

    .getter(org.example.tests.model.inheritance.stat.GenericRecord::getCreatedAt)

    .setter(org.example.tests.model.inheritance.stat.GenericRecord::setCreatedAt))
    .build();

        StaticTableSchema<org.example.tests.model.inheritance.stat.Customer>
CUSTOMER_SCHEMA =

StaticTableSchema.builder(org.example.tests.model.inheritance.stat.Customer.class)

    .newItemSupplier(org.example.tests.model.inheritance.stat.Customer::new)
        .addAttribute(String.class, a -> a.name("name"))

    .getter(org.example.tests.model.inheritance.stat.Customer::getName)

```

```

.setter(org.example.tests.model.inheritance.stat.Customer::setName))
        // 1. Use the extend() method to collapse the parent attributes
onto the child class.
        .extend(GENERIC_RECORD_SCHEMA) // All the attributes of the
GenericRecord schema are added to Customer.
        .build();

```

The previous static schema example uses the following data classes. Because the mapping is defined when you build the static table schema, the data classes don't require annotations.

Data classes

Standard data class

```

public class Customer extends GenericRecord {
    private String name;

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }
}

public abstract class GenericRecord {
    private String id;
    private String createdAt;

    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedAt() { return createdAt; }
    public void setCreatedAt(String createdAt) { this.createdAt =
createdAt; }
}

```

Lombok

```

@Data
@ToString(callSuper = true)
public class Customer extends GenericRecord{
    private String name;
}

@Data

```

```
public abstract class GenericRecord {
    private String id;
    private String createdAt;
}
```

Use composition

If your classes use composition, use the following approaches to flatten the hierarchy.

Use annotated beans

The `@DynamoDbFlatten` annotation flattens the contained class.

The following data class examples use the `@DynamoDbFlatten` annotation to effectively add all attributes of the contained `GenericRecord` class to the `Customer` class.

Standard data class

```
@DynamoDbBean
public class Customer {
    private String name;
    private GenericRecord record;

    public String getName() { return this.name; }
    public void setName(String name) { this.name = name; }

    @DynamoDbFlatten
    public GenericRecord getRecord() { return this.record; }
    public void setRecord(GenericRecord record) { this.record = record; }

    @DynamoDbBean
    public class GenericRecord {
        private String id;
        private String createdAt;

        @DynamoDbPartitionKey
        public String getId() { return this.id; }
        public void setId(String id) { this.id = id; }

        public String getCreatedAt() { return this.createdAt; }
        public void setCreatedAt(String createdAt) { this.createdAt =
            createdAt; }
    }
}
```

```
}

```

Lombok

```
@Data
@DynamoDbBean
public class Customer {
    private String name;
    @Getter(onMethod_=@DynamoDbFlatten)
    private GenericRecord record;
}

@Data
@DynamoDbBean
public class GenericRecord {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;
    private String createdAt;
}

```

You can use the `flatten` annotation to flatten as many different eligible classes as you need to. The following constraints apply:

- All attribute names must be unique after they are flattened.
- There must never be more than one partition key, sort key, or table name.

Use static schemas

When you build a static table schema, use the `flatten()` method of the builder. You also supply the getter and setter methods that identify the contained class.

```
StaticTableSchema<GenericRecord> GENERIC_RECORD_SCHEMA =
    StaticTableSchema.builder(GenericRecord.class)
        .newItemSupplier(GenericRecord::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(GenericRecord::getId)
            .setter(GenericRecord::setId)
            .tags(primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("created_date")
            .getter(GenericRecord::getCreatedAt)

```

```

        .setter(GenericRecord::setCreatedDate))
        .build();

    StaticTableSchema<Customer> CUSTOMER_SCHEMA =
        StaticTableSchema.builder(Customer.class)
            .newItemSupplier(Customer::new)
            .addAttribute(String.class, a -> a.name("name")
                .getter(Customer::getName)
                .setter(Customer::setName))
            // Because we are flattening a component object, we supply a
getter and setter so the
            // mapper knows how to access it.
            .flatten(GENERIC_RECORD_SCHEMA, Customer::getRecord,
Customer::setRecord)
            .build();

```

The previous static schema example uses the following data classes.

Data classes

Standard data class

```

public class Customer {
    private String name;
    private GenericRecord record;

    public String getName() { return this.name; }
    public void setName(String name) { this.name = name; }

    public GenericRecord getRecord() { return this.record; }
    public void setRecord(GenericRecord record) { this.record = record; }

public class GenericRecord {
    private String id;
    private String createdAt;

    public String getId() { return this.id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedAt() { return this.createdAt; }
    public void setCreatedAt(String createdAt) { this.createdAt =
createdAt; }
}

```

Lombok

```
@Data
public class Customer {
    private String name;
    private GenericRecord record;
}

@Data
public class GenericRecord {
    private String id;
    private String createdAt;
}
```

You can use the builder pattern to flatten as many different eligible classes as you need to.

Implications for other code

When you use the `@DynamoDbFlatten` attribute (or `flatten()` builder method), the item in DynamoDB contains an attribute for each attribute of the composed object. It also includes the attributes of the composing object.

In contrast, if you annotate a data class with a composed class and don't use `@DynamoDbFlatten`, the item is saved with the composed object as a single attribute.

For example, compare the `Customer` class shown in the [flattening with composition example](#) with and without flattening of the `record` attribute. You can visualize the difference with JSON as shown in the following table.

With flattening	Without flattening
3 attributes	2 attributes
<pre>{ "id": "1", "createdAt": "today", "name": "my name" }</pre>	<pre>{ "id": "1", "record": { "createdAt": "today", "name": "my name" } }</pre>

The difference becomes important if you have other code accessing the DynamoDB table that expects to find certain attributes.

Work with attributes that are beans, maps, lists and sets

A bean definition, such as the `Person` class shown below, might define properties (or attributes) that refer to types with additional attributes. For instance, in the `Person` class, `mainAddress` is a property that refers to an `Address` bean that defines additional value attributes. `addresses` refers to a Java Map, whose elements refer to `Address` beans. These complex types can be thought of as containers of simple attributes that you use for their data value in the context of DynamoDB.

DynamoDB refers to the value properties of nested elements, such as maps, lists, or beans, as *nested attributes*. The [Amazon DynamoDB Developer Guide](#) refers to the saved form of a Java map, list or bean as a *document type*. Simple attributes that you use for their data value in Java are referred to as *scalar types* in DynamoDB. Sets, which contains multiple scalar elements of the same type, and referred to as *set types*.

It is important to know that the DynamoDB Enhanced Client API converts a property that is bean to a DynamoDB map document type when it is save.

Person class

```
@DynamoDbBean
public class Person {
    private Integer id;
    private String firstName;
    private String lastName;
    private Integer age;
    private Address mainAddress;
    private Map<String, Address> addresses;
    private List<PhoneNumber> phoneNumbers;
    private Set<String> hobbies;

    @DynamoDbPartitionKey
    public Integer getId() {
        return id;
    }

    public void setId(Integer id) {
        this.id = id;
    }
}
```

```
public String getFirstName() {
    return firstName;
}

public void setFirstName(String firstName) {
    this.firstName = firstName;
}

public String getLastName() {
    return lastName;
}

public void setLastName(String lastName) {
    this.lastName = lastName;
}

public Integer getAge() {
    return age;
}

public void setAge(Integer age) {
    this.age = age;
}

public Address getMainAddress() {
    return mainAddress;
}

public void setMainAddress(Address mainAddress) {
    this.mainAddress = mainAddress;
}

public Map<String, Address> getAddresses() {
    return addresses;
}

public void setAddresses(Map<String, Address> addresses) {
    this.addresses = addresses;
}

public List<PhoneNumber> getPhoneNumbers() {
    return phoneNumbers;
}
```

```
public void setPhoneNumbers(List<PhoneNumber> phoneNumbers) {
    this.phoneNumbers = phoneNumbers;
}

public Set<String> getHobbies() {
    return hobbies;
}

public void setHobbies(Set<String> hobbies) {
    this.hobbies = hobbies;
}

@Override
public String toString() {
    return "Person{" +
        "addresses=" + addresses +
        ", id=" + id +
        ", firstName='" + firstName + '\'' +
        ", lastName='" + lastName + '\'' +
        ", age=" + age +
        ", mainAddress=" + mainAddress +
        ", phoneNumbers=" + phoneNumbers +
        ", hobbies=" + hobbies +
        '}';
}
}
```

Address class

```
@DynamoDbBean
public class Address {
    private String street;
    private String city;
    private String state;
    private String zipCode;

    public Address() {
    }

    public String getStreet() {
        return this.street;
    }
}
```

```
public String getCity() {
    return this.city;
}

public String getState() {
    return this.state;
}

public String getZipCode() {
    return this.zipCode;
}

public void setStreet(String street) {
    this.street = street;
}

public void setCity(String city) {
    this.city = city;
}

public void setState(String state) {
    this.state = state;
}

public void setZipCode(String zipCode) {
    this.zipCode = zipCode;
}

@Override
public boolean equals(Object o) {
    if (this == o) return true;
    if (o == null || getClass() != o.getClass()) return false;
    Address address = (Address) o;
    return Objects.equals(street, address.street) && Objects.equals(city,
address.city) && Objects.equals(state, address.state) && Objects.equals(zipCode,
address.zipCode);
}

@Override
public int hashCode() {
    return Objects.hash(street, city, state, zipCode);
}
```

```
@Override
public String toString() {
    return "Address{" +
        "street='" + street + '\'' +
        ", city='" + city + '\'' +
        ", state='" + state + '\'' +
        ", zipCode='" + zipCode + '\'' +
        '}';
}
}
```

PhoneNumber class

```
@DynamoDbBean
public class PhoneNumber {
    String type;
    String number;

    public String getType() {
        return type;
    }

    public void setType(String type) {
        this.type = type;
    }

    public String getNumber() {
        return number;
    }

    public void setNumber(String number) {
        this.number = number;
    }

    @Override
    public String toString() {
        return "PhoneNumber{" +
            "type='" + type + '\'' +
            ", number='" + number + '\'' +
            '}';
    }
}
```

Save complex types

Use annotated data classes

You save nested attributes for custom classes by simply annotating them. The `Address` class and `PhoneNumber` class shown previously are annotated with only the `@DynamoDbBean` annotation. When the DynamoDB Enhanced Client API builds the table schema for the `Person` class with the following snippet, the API discovers the use of the `Address` and `PhoneNumber` classes and builds the corresponding mappings to work with DynamoDB.

```
TableSchema<Person> personTableSchema = TableSchema.fromBean(Person.class);
```

Use abstract schemas with builders

The alternative approach is to use static table schema builders for each nested bean class as shown in the following code.

The table schemas for the `Address` and `PhoneNumber` classes are abstract in the sense that they cannot be used with a DynamoDB table. This is because they lack definitions for the primary key. They are used, however, as nested schemas in the table schema for the `Person` class.

After comment lines 1 and 2 in the definition of `PERSON_TABLE_SCHEMA`, you see the code that uses the abstract table schemas. The use of `documentOf` in the `EnhanceType.documentOf(...)` method does not indicate that the method returns an `EnhancedDocument` type of the Enhanced Document API. The `documentOf(...)` method in this context returns an object that knows how to map its class argument to and from DynamoDB table attributes by using the table schema argument.

Static schema code

```
// Abstract table schema that cannot be used to work with a DynamoDB table,  
// but can be used as a nested schema.  
public static final TableSchema<Address> TABLE_SCHEMA_ADDRESS =  
TableSchema.builder(Address.class)  
    .newItemSupplier(Address::new)  
    .addAttribute(String.class, a -> a.name("street")  
        .getter(Address::getStreet)  
        .setter(Address::setStreet))  
    .addAttribute(String.class, a -> a.name("city")  
        .getter(Address::getCity)  
        .setter(Address::setCity))  
    .addAttribute(String.class, a -> a.name("zipcode"))
```

```

        .getter(Address::getZipCode)
        .setter(Address::setZipCode))
    .addAttribute(String.class, a -> a.name("state")
        .getter(Address::getState)
        .setter(Address::setState))
    .build();

// Abstract table schema that cannot be used to work with a DynamoDB table,
// but can be used as a nested schema.
public static final TableSchema<PhoneNumber> TABLE_SCHEMA_PHONENUMBER =
TableSchema.builder(PhoneNumber.class)
    .newItemSupplier(PhoneNumber::new)
    .addAttribute(String.class, a -> a.name("type")
        .getter(PhoneNumber::getType)
        .setter(PhoneNumber::setType))
    .addAttribute(String.class, a -> a.name("number")
        .getter(PhoneNumber::getNumber)
        .setter(PhoneNumber::setNumber))
    .build();

// A static table schema that can be used with a DynamoDB table.
// The table schema contains two nested schemas that are used to perform mapping
to/from DynamoDB.
public static final TableSchema<Person> PERSON_TABLE_SCHEMA =
    TableSchema.builder(Person.class)
        .newItemSupplier(Person::new)
        .addAttribute(Integer.class, a -> a.name("id")
            .getter(Person::getId)
            .setter(Person::setId)
            .addTag(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("firstName")
            .getter(Person::getFirstName)
            .setter(Person::setFirstName))
        .addAttribute(String.class, a -> a.name("lastName")
            .getter(Person::getLastName)
            .setter(Person::setLastName))
        .addAttribute(Integer.class, a -> a.name("age")
            .getter(Person::getAge)
            .setter(Person::setAge))
        .addAttribute(EnhancedType.documentOf(Address.class, TABLE_SCHEMA_ADDRESS),
a -> a.name("mainAddress")
            .getter(Person::getMainAddress)
            .setter(Person::setMainAddress))
        .addAttribute(EnhancedType.listOf(String.class), a -> a.name("hobbies"))

```

```

        .getter(Person::getHobbies)
        .setter(Person::setHobbies))
    .addAttribute(EnhancedType.mapOf(
        EnhancedType.of(String.class),
        // 1. Use mapping functionality of the Address table schema.
        EnhancedType.documentOf(Address.class, TABLE_SCHEMA_ADDRESS)), a ->
a.name("addresses")
        .getter(Person::getAddresses)
        .setter(Person::setAddresses))
    .addAttribute(EnhancedType.listOf(
        // 2. Use mapping functionality of the PhoneNumber table schema.
        EnhancedType.documentOf(PhoneNumber.class, TABLE_SCHEMA_PHONENUMBER)),
a -> a.name("phoneNumbers")
        .getter(Person::getPhoneNumbers)
        .setter(Person::setPhoneNumbers))
    .build();

```

Project attributes of complex types

For `query()` and `scan()` methods, you can specify which attributes you want to be returned in the results by using method calls such as `addNestedAttributeToProject()` and `attributesToProject()`. The DynamoDB Enhanced Client API converts the Java method call parameters into [projection expressions](#) before the request is sent.

The following example populates the `Person` table with two items, then performs three scan operations.

The first scan accesses all items in the table in order to compare the results to the other scan operations.

The second scan uses the [addNestedAttributeToProject\(\)](#) builder method to return only the `street` attribute value.

The third scan operation uses the [attributesToProject\(\)](#) builder method to return the data for the first-level attribute, `hobbies`. The attribute type of `hobbies` is a list. To access individual list items, perform a `get()` operation on the list.

```

    personDynamoDbTable = getDynamoDbEnhancedClient().table("Person",
PERSON_TABLE_SCHEMA);
    PersonUtils.createPersonTable(personDynamoDbTable, getDynamoDbClient());
    // Use a utility class to add items to the Person table.
    List<Person> personList = PersonUtils.getItemsForCount(2);

```

```

    // This utility method performs a put against DynamoDB to save the instances in
    the list argument.
    PersonUtils.putCollection(getDynamoDbEnhancedClient(), personList,
    personDynamoDbTable);

    // The first scan logs all items in the table to compare to the results of the
    subsequent scans.
    final PageIterable<Person> allItems = personDynamoDbTable.scan();
    allItems.items().forEach(p ->
        // 1. Log what is in the table.
        logger.info(p.toString()));

    // Scan for nested attributes.
    PageIterable<Person> streetScanResult = personDynamoDbTable.scan(b -> b
        // Use the 'addNestedAttributeToProject()' or
    'addNestedAttributesToProject()' to access data nested in maps in DynamoDB.
        .addNestedAttributeToProject(
            NestedAttributeName.create("addresses", "work", "street")
        ));

    streetScanResult.items().forEach(p ->
        //2. Log the results of requesting nested attributes.
        logger.info(p.toString()));

    // Scan for a top-level list attribute.
    PageIterable<Person> hobbiesScanResult = personDynamoDbTable.scan(b -> b
        // Use the 'attributesToProject()' method to access first-level
    attributes.
        .attributesToProject("hobbies"));

    hobbiesScanResult.items().forEach((p) -> {
        // 3. Log the results of the request for the 'hobbies' attribute.
        logger.info(p.toString());
        // To access an item in a list, first get the parent attribute, 'hobbies',
    then access items in the list.
        String hobby = p.getHobbies().get(1);
        // 4. Log an item in the list.
        logger.info(hobby);
    });

```

```

// Logged results from comment line 1.
Person{id=2, firstName='first name 2', lastName='last name 2', age=11,
    addresses={work=Address{street='street 21', city='city 21', state='state 21',

```

```

zipCode='33333'}, home=Address{street='street 2', city='city 2', state='state 2',
zipCode='22222'}}, phoneNumbers=[PhoneNumber{type='home', number='222-222-2222'},
PhoneNumber{type='work', number='333-333-3333'}]}, hobbies=[hobby 2, hobby 21]]
Person{id=1, firstName='first name 1', lastName='last name 1', age=11,
addresses={work=Address{street='street 11', city='city 11', state='state 11',
zipCode='22222'}, home=Address{street='street 1', city='city 1', state='state 1',
zipCode='11111'}}, phoneNumbers=[PhoneNumber{type='home', number='111-111-1111'},
PhoneNumber{type='work', number='222-222-2222'}]}, hobbies=[hobby 1, hobby 11]]

// Logged results from comment line 2.
Person{id=null, firstName='null', lastName='null', age=null,
addresses={work=Address{street='street 21', city='null', state='null',
zipCode='null'}}}, phoneNumbers=null, hobbies=null}
Person{id=null, firstName='null', lastName='null', age=null,
addresses={work=Address{street='street 11', city='null', state='null',
zipCode='null'}}}, phoneNumbers=null, hobbies=null}

// Logged results from comment lines 3 and 4.
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
phoneNumbers=null, hobbies=[hobby 2, hobby 21]]
hobby 21
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
phoneNumbers=null, hobbies=[hobby 1, hobby 11]]
hobby 11

```

Note

If the `attributesToProject()` method follows any other builder method that adds attributes that you want to project, the list of attribute names supplied to the `attributesToProject()` replaces all other attribute names.

A scan performed with the `ScanEnhancedRequest` instance in the following snippet returns only hobby data.

```

ScanEnhancedRequest lastOverwrites = ScanEnhancedRequest.builder()
    .addNestedAttributeToProject(
        NestedAttributeName.create("addresses", "work", "street"))
    .addAttributeToProject("firstName")
    // If the 'attributesToProject()' method follows other builder methods
    that add attributes for projection,
    // its list of attributes replace all previous attributes.
    .attributesToProject("hobbies")
    .build();

```

```

PageIterable<Person> hobbiesOnlyResult =
    personDynamoDbTable.scan(lastOverwrites);
hobbiesOnlyResult.items().forEach(p ->
    logger.info(p.toString()));

// Logged results.
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
    phoneNumbers=null, hobbies=[hobby 2, hobby 21]}
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
    phoneNumbers=null, hobbies=[hobby 1, hobby 11]}

```

The following code snippet uses the `attributesToProject()` method first. This ordering preserves all other requested attributes.

```

ScanEnhancedRequest attributesPreserved = ScanEnhancedRequest.builder()
    // Use 'attributesToProject()' first so that the method call does not
    // replace all other attributes
    // that you want to project.
    .attributesToProject("firstName")
    .addNestedAttributeToProject(
        NestedAttributeName.create("addresses", "work", "street"))
    .addAttributeToProject("hobbies")
    .build();
PageIterable<Person> allAttributesResult =
    personDynamoDbTable.scan(attributesPreserved);
allAttributesResult.items().forEach(p ->
    logger.info(p.toString()));

// Logged results.
Person{id=null, firstName='first name 2', lastName='null', age=null,
    addresses={work=Address{street='street 21', city='null', state='null',
    zipCode='null'}}}, phoneNumbers=null, hobbies=[hobby 2, hobby 21]}
Person{id=null, firstName='first name 1', lastName='null', age=null,
    addresses={work=Address{street='street 11', city='null', state='null',
    zipCode='null'}}}, phoneNumbers=null, hobbies=[hobby 1, hobby 11]}

```

Use complex types in expressions

You can use complex types in expressions, such as filter expressions and condition expressions, by using dereferencing operators to navigate the structure of the complex type. For objects and maps, use the `.` (dot) and for list elements use `[n]` (square brackets around the sequence number

of the element). You can't refer to individual elements of a set, but you can use the [contains function](#).

The following example show two filter expressions that are used in scan operations. The filter expressions specify the match conditions for items you want in the results. The example uses `Person`, `Address`, and `PhoneNumber` classes shown previously.

```
public void scanUsingFilterOfNestedAttr() {
    // The following is a filter expression for an attribute that is a map of
    Address objects.
    // By using this filter expression, the SDK returns Person objects that have an
    address
    // with 'mailing' as a key and 'MS2' for a state value.
    Expression addressFilter = Expression.builder()
        .expression("addresses.#type.#field = :value")
        .putExpressionName("#type", "mailing")
        .putExpressionName("#field", "state")
        .putExpressionValue(":value",
AttributeValue.builder().s("MS2").build())
        .build();

    PageIterable<Person> addressFilterResults = personDynamoDbTable.scan(rb -> rb.
        filterExpression(addressFilter));
    addressFilterResults.items().stream().forEach(p -> logger.info("Person: {}",
p));

    assert addressFilterResults.items().stream().count() == 1;

    // The following is a filter expression for an attribute that is a list of
    phone numbers.
    // By using this filter expression, the SDK returns Person objects whose second
    phone number
    // in the list has a type equal to 'cell'.
    Expression phoneFilter = Expression.builder()
        .expression("phoneNumbers[1].#type = :type")
        .putExpressionName("#type", "type")
        .putExpressionValue(":type",
AttributeValue.builder().s("cell").build())
        .build();

    PageIterable<Person> phoneFilterResults = personDynamoDbTable.scan(rb -> rb
        .filterExpression(phoneFilter)
```

```

        .attributesToProject("id", "firstName", "lastName", "phoneNumbers")
    );

    phoneFilterResults.items().stream().forEach(p -> logger.info("Person: {}", p));

    assert phoneFilterResults.items().stream().count() == 1;
    assert
phoneFilterResults.items().stream().findFirst().get().getPhoneNumbers().get(1).getType().equal
    }

```

Helper method that populates the table

```

public static void populateDatabase() {
    Person person1 = new Person();
    person1.setId(1);
    person1.setFirstName("FirstName1");
    person1.setLastName("LastName1");

    Address billingAddr1 = new Address();
    billingAddr1.setState("BS1");
    billingAddr1.setCity("BillingTown1");

    Address mailing1 = new Address();
    mailing1.setState("MS1");
    mailing1.setCity("MailingTown1");

    person1.setAddresses(Map.of("billing", billingAddr1, "mailing", mailing1));

    PhoneNumber pn1_1 = new PhoneNumber();
    pn1_1.setType("work");
    pn1_1.setNumber("111-111-1111");

    PhoneNumber pn1_2 = new PhoneNumber();
    pn1_2.setType("home");
    pn1_2.setNumber("222-222-2222");

    List<PhoneNumber> phoneNumbers1 = List.of(pn1_1, pn1_2);
    person1.setPhoneNumbers(phoneNumbers1);

    personDynamoDbTable.putItem(person1);

    Person person2 = person1;
    person2.setId(2);
}

```

```
person2.setFirstName("FirstName2");
person2.setLastName("LastName2");

Address billingAddress2 = billingAddr1;
billingAddress2.setCity("BillingTown2");
billingAddress2.setState("BS2");

Address mailing2 = mailing1;
mailing2.setCity("MailingTown2");
mailing2.setState("MS2");

person2.setAddresses(Map.of("billing", billingAddress2, "mailing", mailing2));

PhoneNumber pn2_1 = new PhoneNumber();
pn2_1.setType("work");
pn2_1.setNumber("333-333-3333");

PhoneNumber pn2_2 = new PhoneNumber();
pn2_2.setType("cell");
pn2_2.setNumber("444-444-4444");

List<PhoneNumber> phoneNumbers2 = List.of(pn2_1, pn2_2);
person2.setPhoneNumbers(phoneNumbers2);

personDynamoDbTable.putItem(person2);
}
```

JSON representation of items in the database

```
{

      "type": "cell"
    }
  ]
}
```

```
}
```

Update items that contain complex types

To update an item that contains complex types, you have two basic approaches:

- Approach 1: First retrieve the item (by using `getItem`), update the object, then call `DynamoDbTable#updateItem`.
- Approach 2: Don't retrieve the item, but construct a new instance, set the properties you want to update, and submit the instance to `DynamoDbTable#updateItem` by setting the appropriate value of [IgnoreNullsMode](#). This approach does not require that you fetch the item before updating it.

The examples shown in this section use the `Person`, `Address`, and `PhoneNumber` classes shown previously.

Update approach 1: retrieve, then update

By using this approach, you ensure that no data is lost on update. The DynamoDB Enhanced Client API recreates the bean with the attributes from the item saved in DynamoDB including values of complex types. You then need to use the getters and setters to update the bean. The downside of this approach is the cost you incur retrieving the item first.

The following example demonstrates that no data is lost if you first retrieve the item before updating it.

```
public void retrieveThenUpdateExample() {
    // Assume that we ran this code yesterday.
    Person person = new Person();
    person.setId(1);
    person.setFirstName("FirstName");
    person.setLastName("LastName");

    Address mainAddress = new Address();
    mainAddress.setStreet("123 MyStreet");
    mainAddress.setCity("MyCity");
    mainAddress.setState("MyState");
    mainAddress.setZipCode("MyZipCode");
    person.setMainAddress(mainAddress);

    PhoneNumber homePhone = new PhoneNumber();
```

```
    homePhone.setNumber("1111111");
    homePhone.setType("HOME");
    person.setPhoneNumbers(List.of(homePhone));

    personDynamoDbTable.putItem(person);

    // Assume that we are running this code now.
    // First, retrieve the item
    Person retrievedPerson =
personDynamoDbTable.getItem(Key.builder().partitionValue(1).build());

    // Make any updates.
    retrievedPerson.getMainAddress().setCity("YourCity");

    // Save the updated bean. 'updateItem' returns the bean as it appears after the
update.
    Person updatedPerson = personDynamoDbTable.updateItem(retrievedPerson);

    // Verify for this example.
    Address updatedMainAddress = updatedPerson.getMainAddress();
    assert updatedMainAddress.getCity().equals("YourCity");
    assert updatedMainAddress.getState().equals("MyState"); // Unchanged.
    // The list of phone numbers remains; it was not set to null;
    assert updatedPerson.getPhoneNumbers().size() == 1;
}
```

Update approach 2: Use an IgnoreNullsMode enum without retrieving the item first

To update an item in DynamoDB, you can provide a new object that has only the properties that you want updated and leave the other values as null. With this approach, you need to be aware of how null values in the object are treated by the SDK and how you can control the behavior.

To specify which null-valued properties you want the SDK to ignore, provide an `IgnoreNullsMode` enum when you build the [UpdateItemEnhancedRequest](#). As an example of using one of the enumerated values, the following snippet uses the `IgnoreNullsMode.SCALAR_ONLY` mode.

```
// Create a new Person object to update the existing item in DynamoDB.
Person personForUpdate = new Person();
personForUpdate.setId(1);
personForUpdate.setFirstName("updatedFirstName"); // 'firstName' is a top scalar
property.
```

```
Address addressForUpdate = new Address();
addressForUpdate.setCity("updatedCity");
personForUpdate.setMainAddress(addressForUpdate);
```

```
personDynamoDbTable.updateItem(r -> r
    .item(personForUpdate)
    .ignoreNullsMode(IgnoreNullsMode.SCALAR_ONLY)
    .build());
```

/* With `IgnoreNullsMode.SCALAR_ONLY` provided, The SDK ignores all null properties. The SDK adds or replaces the 'firstName' property with the provided value, "updatedFirstName". The SDK updates the 'city' value of 'mainAddress', as long as the 'mainAddress' attribute already exists in DynamoDB.

In the background, the SDK generates an update expression that it sends in the request to DynamoDB.

The following JSON object is a simplified version of what it sends. Notice that the SDK includes the paths

to 'mainAddress.city' and 'firstName' in the SET clause of the update expression. No null values in

'personForUpdate' are included.

```
{
  "TableName": "PersonTable",
  "Key": {
    "id": {
      "N": "1"
    }
  },
  "ReturnValues": "ALL_NEW",
  "UpdateExpression": "SET #mainAddress.#city = :mainAddress_city, #firstName = :firstName",
  "ExpressionAttributeNames": {
    "#city": "city",
    "#firstName": "firstName",
    "#mainAddress": "mainAddress"
  },
  "ExpressionAttributeValues": {
    ":firstName": {
      "S": "updatedFirstName"
    },
    ":mainAddress_city": {
      "S": "updatedCity"
    }
  }
}
```

```

    }
  }
}

```

Had we chosen `IgnoreNullsMode.DEFAULT` instead of `IgnoreNullsMode.SCALAR_ONLY`, the SDK would have included null values in the `"ExpressionAttributeValues"` section of the request as shown in the following snippet.

```

"ExpressionAttributeValues": {
  ":mainAddress": {
    "M": {
      "zipCode": {
        "NULL": true
      },
      "city": {
        "S": "updatedCity"
      },
      "street": {
        "NULL": true
      },
      "state": {
        "NULL": true
      }
    }
  },
  ":firstName": {
    "S": "updatedFirstName"
  }
}
*/

```

The Amazon DynamoDB Developer Guide contains more information about [update expressions](#).

Descriptions of the `IgnoreNullsMode` options

- `IgnoreNullsMode.SCALAR_ONLY` - Use this setting to update scalar attributes at any level. The SDK constructs an update statement that sends only non-null, scalar attributes to DynamoDB. The SDK ignores null-valued, scalar attributes of a bean or map, retaining the saved value in DynamoDB.

When you update a scalar attribute of map or bean, the map must already exist in DynamoDB. If you add a map or a bean to the object that does not already exist for the object in DynamoDB,

you get a `DynamoDbException` with the message *The document path provided in the update expression is invalid for update*. You must use `MAPS_ONLY` mode to add a bean or map to DynamoDB before you update any of its attributes.

- `IgnoreNullsMode.MAPS_ONLY` - Use this setting to add or replace properties that are a bean or a map. The SDK replaces or adds any map or bean provided in the object. Any beans or maps that are null in the object are ignored, retaining the map that exists in DynamoDB.
- `IgnoreNullsMode.DEFAULT` - With this setting, the SDK never ignores null values. Scalar attributes at any level that are null are updated to null. The SDK updates any null-valued bean, map, list, or set property in the object to null in DynamoDB. When you use this mode—or don't provide a mode since it's the default mode—you should retrieve the item first so that values in DynamoDB are not set to null that are provided in the object for updating, unless your intention is to set the values to null.

In all modes, if you provide an object to `updateItem` that has a non-null list or set, the list or set is saved to DynamoDB.

Why the modes?

When you provide an object with a bean or map to the `updateItem` method, the SDK can't tell if it should use the property values in the bean (or entry values in the map) to update the item, or if the entire bean/map should replace what's been saved to DynamoDB.

Working from our previous example that shows the retrieval of the item first, let's attempt to update the `city` attribute of `mainAddress` without the retrieval.

```
/* The retrieval example saved the Person object with a 'mainAddress' property whose
   'city' property value is "MyCity".
   /* Note that we create a new Person with only the necessary information to update the
   city value
   of the mainAddress. */
Person personForUpdate = new Person();
personForUpdate.setId(1);
// The update we want to make changes the city.
Address mainAddressForUpdate = new Address();
mainAddressForUpdate.setCity("YourCity");
personForUpdate.setMainAddress(mainAddressForUpdate);

// Lets' try the following:
Person updatedPerson = personDynamoDbTable.updateItem(personForUpdate);
/*
```

Since we haven't retrieved the item, we don't know if the 'mainAddress' property already exists, so what update expression should the SDK generate?

A) Should it replace or add the 'mainAddress' with the provided object (setting all attributes to null other than city) as shown in the following simplified JSON?

```
{
  "TableName": "PersonTable",
  "Key": {
    "id": {
      "N": "1"
    }
  },
  "ReturnValues": "ALL_NEW",
  "UpdateExpression": "SET #mainAddress = :mainAddress",
  "ExpressionAttributeNames": {
    "#mainAddress": "mainAddress"
  },
  "ExpressionAttributeValues": {
    ":mainAddress": {
      "M": {
        "zipCode": {
          "NULL": true
        },
        "city": {
          "S": "YourCity"
        },
        "street": {
          "NULL": true
        },
        "state": {
          "NULL": true
        }
      }
    }
  }
}
```

B) Or should it update only the 'city' attribute of an existing 'mainAddress' as shown in the following simplified JSON?

```
{
  "TableName": "PersonTable",
```

```

    "Key": {
      "id": {
        "N": "1"
      }
    },
    "ReturnValues": "ALL_NEW",
    "UpdateExpression": "SET #mainAddress.#city = :mainAddress_city",
    "ExpressionAttributeNames": {
      "#city": "city",
      "#mainAddress": "mainAddress"
    },
    "ExpressionAttributeValues": {
      ":mainAddress_city": {
        "S": "YourCity"
      }
    }
  }
}

```

However, assume that we don't know if the 'mainAddress' already exists. If it doesn't exist, the SDK would try to update an attribute of a non-existent map, which results in an exception.

In this particular case, we would likely select option B (SCALAR_ONLY) to retain the other values of the 'mainAddress'.

*/

The following two examples show uses of the MAPS_ONLY and SCALAR_ONLY enumerated values. MAPS_ONLY adds a map and SCALAR_ONLY updates a map.

IgnoreNullsMode.MAPS_ONLY example

```

public void mapsOnlyModeExample() {
    // Assume that we ran this code yesterday.
    Person person = new Person();
    person.setId(1);
    person.setFirstName("FirstName");

    personDynamoDbTable.putItem(person);

    // Assume that we are running this code now.

    /* Note that we create a new Person with only the necessary information to
    update the city value

```

```

of the mainAddress. */
Person personForUpdate = new Person();
personForUpdate.setId(1);
// The update we want to make changes the city.
Address mainAddressForUpdate = new Address();
mainAddressForUpdate.setCity("YourCity");
personForUpdate.setMainAddress(mainAddressForUpdate);

Person updatedPerson = personDynamoDbTable.updateItem(r -> r
    .item(personForUpdate)
    .ignoreNullsMode(IgnoreNullsMode.MAPS_ONLY)); // Since the mainAddress
property does not exist, use MAPS_ONLY mode.
assert updatedPerson.getMainAddress().getCity().equals("YourCity");
assert updatedPerson.getMainAddress().getState() == null;
}

```

IgnoreNullsMode.SCALAR_ONLY example

```

public void scalarOnlyExample() {
    // Assume that we ran this code yesterday.
    Person person = new Person();
    person.setId(1);
    Address mainAddress = new Address();
    mainAddress.setCity("MyCity");
    mainAddress.setState("MyState");
    person.setMainAddress(mainAddress);

    personDynamoDbTable.putItem(person);

    // Assume that we are running this code now.

    /* Note that we create a new Person with only the necessary information to
update the city value
of the mainAddress. */
    Person personForUpdate = new Person();
    personForUpdate.setId(1);
    // The update we want to make changes the city.
    Address mainAddressForUpdate = new Address();
    mainAddressForUpdate.setCity("YourCity");
    personForUpdate.setMainAddress(mainAddressForUpdate);

    Person updatedPerson = personDynamoDbTable.updateItem(r -> r

```

```

        .item(personForUpdate)
        .ignoreNullsMode(IgnoreNullsMode.SCALAR_ONLY)); // SCALAR_ONLY mode
ignores null properties in the in mainAddress.
    assert updatedPerson.getMainAddress().getCity().equals("YourCity");
    assert updatedPerson.getMainAddress().getState().equals("MyState"); // The
state property remains the same.
}

```

Refer to the following table to see which null values are ignored for each mode. You can often work with either SCALAR_ONLY and MAPS_ONLY except when you work with beans or maps.

Which null-valued properties in the object submitted to `updateItem` does the SDK ignore for each mode?

Type of property	in SCALAR_ONLY mode	in MAPS_ONLY mode	in DEFAULT mode
Top scalar	Yes	Yes	No
Bean or map	Yes	Yes	No
Scalar value of a bean or map entry	Yes ¹	No ²	No
List or set	Yes	Yes	No

¹This assumes the map already exists in DynamoDB. Any scalar value—null or not null—of the bean or map that you provide in the object for update requires that a path to the value exists in DynamoDB. The SDK constructs a path to the attribute by using the `.` (dot) dereference operator before it submits the request.

²Since you use MAPS_ONLY mode to fully replace or to add a bean or map, all null values in the bean or map are retained in the map saved to DynamoDB.

Preserve empty objects with `@DynamoDbPreserveEmptyObject`

If you save a bean to Amazon DynamoDB with empty objects and you want the SDK to recreate the empty objects upon retrieval, annotate the getter of the inner bean with `@DynamoDbPreserveEmptyObject`.

To illustrate how the annotation works, the code example uses the following two beans.

Example beans

The following data class contains two `InnerBean` fields. The getter method, `getInnerBeanWithoutAnno()`, is not annotated with `@DynamoDbPreserveEmptyObject`. The `getInnerBeanWithAnno()` method is annotated.

```
@DynamoDbBean
public class MyBean {

    private String id;
    private String name;
    private InnerBean innerBeanWithoutAnno;
    private InnerBean innerBeanWithAnno;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }

    public InnerBean getInnerBeanWithoutAnno() { return innerBeanWithoutAnno; }
    public void setInnerBeanWithoutAnno(InnerBean innerBeanWithoutAnno)
    { this.innerBeanWithoutAnno = innerBeanWithoutAnno; }

    @DynamoDbPreserveEmptyObject
    public InnerBean getInnerBeanWithAnno() { return innerBeanWithAnno; }
    public void setInnerBeanWithAnno(InnerBean innerBeanWithAnno)
    { this.innerBeanWithAnno = innerBeanWithAnno; }

    @Override
    public String toString() {
        return new StringJoiner(", ", MyBean.class.getSimpleName() + "[", "]")
            .add("innerBeanWithoutAnno=" + innerBeanWithoutAnno)
            .add("innerBeanWithAnno=" + innerBeanWithAnno)
            .add("id='" + id + "'")
            .add("name='" + name + "'")
            .toString();
    }
}
```

Instances of the following `InnerBean` class are fields of `MyBean` and are initialized as empty objects in the example code.

```

@DynamoDbBean
public class InnerBean {

    private String innerBeanField;

    public String getInnerBeanField() {
        return innerBeanField;
    }

    public void setInnerBeanField(String innerBeanField) {
        this.innerBeanField = innerBeanField;
    }

    @Override
    public String toString() {
        return "InnerBean{" +
            "innerBeanField='" + innerBeanField + '\'' +
            '}';
    }
}

```

The following code example saves a `MyBean` object with initialized inner beans to DynamoDB and then retrieves the item. The logged output shows that the `innerBeanWithoutAnno` is not initialized, but `innerBeanWithAnno` has been created.

```

public MyBean preserveEmptyObjectAnnoUsingGetItemExample(DynamoDbTable<MyBean>
myBeanTable) {
    // Save an item to DynamoDB.
    MyBean bean = new MyBean();
    bean.setId("1");
    bean.setInnerBeanWithoutAnno(new InnerBean()); // Instantiate the inner bean.
    bean.setInnerBeanWithAnno(new InnerBean()); // Instantiate the inner bean.
    myBeanTable.putItem(bean);

    GetItemEnhancedRequest request = GetItemEnhancedRequest.builder()
        .key(Key.builder().partitionValue("1").build())
        .build();
    MyBean myBean = myBeanTable.getItem(request);

    logger.info(myBean.toString());
    // Output 'MyBean[innerBeanWithoutAnno=null,
innerBeanWithAnno=InnerBean{innerBeanField='null'}, id='1', name='null']'.
}

```

```
    return myBean;
}
```

Alternative static schema

You can use the following `StaticTableSchema` version of the table schemas in place of the annotations on the beans.

```
public static TableSchema<MyBean> buildStaticSchemas() {

    StaticTableSchema<InnerBean> innerBeanStaticTableSchema =
        StaticTableSchema.builder(InnerBean.class)
            .newItemSupplier(InnerBean::new)
            .addAttribute(String.class, a -> a.name("innerBeanField")
                .getter(InnerBean::getInnerBeanField)
                .setter(InnerBean::setInnerBeanField))
            .build();

    return StaticTableSchema.builder(MyBean.class)
        .newItemSupplier(MyBean::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(MyBean::getId)
            .setter(MyBean::setId)
            .addTag(primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("name")
            .getter(MyBean::getName)
            .setter(MyBean::setName))
        .addAttribute(EnhancedType.documentOf(InnerBean.class,
            innerBeanStaticTableSchema),
            a -> a.name("innerBean1")
                .getter(MyBean::getInnerBeanWithoutAnno)
                .setter(MyBean::setInnerBeanWithoutAnno))
        .addAttribute(EnhancedType.documentOf(InnerBean.class,
            innerBeanStaticTableSchema,
            b -> b.preserveEmptyObject(true)),
            a -> a.name("innerBean2")
                .getter(MyBean::getInnerBeanWithAnno)
                .setter(MyBean::setInnerBeanWithAnno))
        .build();
}
```

Avoid saving null attributes of nested objects

You can skip null attributes of nested objects when saving a data class object to DynamoDB by applying the `@DynamoDbIgnoreNulls` annotation. By contrast, top-level attributes with null values are never saved to the database.

To illustrate how the annotation works, the code example uses the following two beans.

Example beans

The following data class contains two `InnerBean` fields. The getter method, `getInnerBeanWithoutAnno()`, is not annotated. The `getInnerBeanWithIgnoreNullsAnno()` method is annotated with `@DynamoDbIgnoreNulls`.

```
@DynamoDbBean
public class MyBean {

    private String id;
    private String name;
    private InnerBean innerBeanWithoutAnno;
    private InnerBean innerBeanWithIgnoreNullsAnno;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }

    public InnerBean getInnerBeanWithoutAnno() { return innerBeanWithoutAnno; }
    public void setInnerBeanWithoutAnno(InnerBean innerBeanWithoutAnno)
    { this.innerBeanWithoutAnno = innerBeanWithoutAnno; }

    @DynamoDbIgnoreNulls
    public InnerBean getInnerBeanWithIgnoreNullsAnno() { return
innerBeanWithIgnoreNullsAnno; }
    public void setInnerBeanWithIgnoreNullsAnno(InnerBean innerBeanWithAnno)
    { this.innerBeanWithIgnoreNullsAnno = innerBeanWithAnno; }

    @Override
    public String toString() {
        return new StringJoiner(", ", MyBean.class.getSimpleName() + "[", "]")
            .add("innerBeanWithoutAnno=" + innerBeanWithoutAnno)
```

```

        .add("innerBeanWithIgnoreNullsAnno=" + innerBeanWithIgnoreNullsAnno)
        .add("id='" + id + "'")
        .add("name='" + name + "'")
        .toString();
    }
}

```

Instances of the following `InnerBean` class are fields of `MyBean` and are used in the following example code.

```

@DynamoDbBean
public class InnerBean {

    private String innerBeanFieldString;
    private Integer innerBeanFieldInteger;

    public String getInnerBeanFieldString() { return innerBeanFieldString; }
    public void setInnerBeanFieldString(String innerBeanFieldString)
    { this.innerBeanFieldString = innerBeanFieldString; }

    public Integer getInnerBeanFieldInteger() { return innerBeanFieldInteger; }
    public void setInnerBeanFieldInteger(Integer innerBeanFieldInteger)
    { this.innerBeanFieldInteger = innerBeanFieldInteger; }

    @Override
    public String toString() {
        return new StringJoiner(", ", InnerBean.class.getSimpleName() + "[", "]")
            .add("innerBeanFieldString='" + innerBeanFieldString + "'")
            .add("innerBeanFieldInteger=" + innerBeanFieldInteger)
            .toString();
    }
}

```

The following code example creates an `InnerBean` object and sets only one of its two attributes with a value.

```

public void ignoreNullsAnnoUsingPutItemExample(DynamoDbTable<MyBean> myBeanTable) {
    // Create an InnerBean object and give only one attribute a value.
    InnerBean innerBeanOneAttributeSet = new InnerBean();
    innerBeanOneAttributeSet.setInnerBeanFieldInteger(200);
}

```

```

        // Create a MyBean instance and use the same InnerBean instance both for
        attributes.
        MyBean bean = new MyBean();
        bean.setId("1");
        bean.setInnerBeanWithoutAnno(innerBeanOneAttributeSet);
        bean.setInnerBeanWithIgnoreNullsAnno(innerBeanOneAttributeSet);

        Map<String, AttributeValue> itemMap = myBeanTable.tableSchema().itemToMap(bean,
true);
        logger.info(itemMap.toString());
        // Log the map that is sent to the database.
        //
        {innerBeanWithIgnoreNullsAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200)}),
id=AttributeValue(S=1),
innerBeanWithoutAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200),
innerBeanFieldString=AttributeValue(NUL=true)}})}

        // Save the MyBean object to the table.
        myBeanTable.putItem(bean);
    }

```

To visualize the low-level data that is sent to DynamoDB, the code logs the attribute map before saving the MyBean object.

The logged output shows that the `innerBeanWithIgnoreNullsAnno` outputs one attribute,

```
innerBeanWithIgnoreNullsAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200)})
```

The `innerBeanWithoutAnno` instance outputs two attributes. One attribute has a value of 200 and the other is a null-valued attribute.

```
innerBeanWithoutAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200),
innerBeanFieldString=AttributeValue(NUL=true)})
```

JSON representation of the attribute map

The following JSON representation makes it easier to see the data that is saved to DynamoDB.

```
{
  "id": {
    "S": "1"
  },

```

```

"innerBeanWithIgnoreNullsAnno": {
  "M": {
    "innerBeanFieldInteger": {
      "N": "200"
    }
  }
},
"innerBeanWithoutAnno": {
  "M": {
    "innerBeanFieldInteger": {
      "N": "200"
    },
    "innerBeanFieldString": {
      "NULL": true
    }
  }
}
}

```

Alternative static schema

You can use the following `StaticTableSchema` version of the table schemas in place data class annotations.

```

public static TableSchema<MyBean> buildStaticSchemas() {

    StaticTableSchema<InnerBean> innerBeanStaticTableSchema =
        StaticTableSchema.builder(InnerBean.class)
            .newItemSupplier(InnerBean::new)
            .addAttribute(String.class, a -> a.name("innerBeanFieldString")
                .getter(InnerBean::getInnerBeanFieldString)
                .setter(InnerBean::setInnerBeanFieldString))
            .addAttribute(Integer.class, a -> a.name("innerBeanFieldInteger")
                .getter(InnerBean::getInnerBeanFieldInteger)
                .setter(InnerBean::setInnerBeanFieldInteger))
            .build();

    return StaticTableSchema.builder(MyBean.class)
        .newItemSupplier(MyBean::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(MyBean::getId)
            .setter(MyBean::setId)
            .addTag(primaryPartitionKey()))

```

```
.addAttribute(String.class, a -> a.name("name")
    .getter(MyBean::getName)
    .setter(MyBean::setName))
.addAttribute(EnhancedType.documentOf(InnerBean.class,
    innerBeanStaticTableSchema),
    a -> a.name("innerBeanWithoutAnno")
    .getter(MyBean::getInnerBeanWithoutAnno)
    .setter(MyBean::setInnerBeanWithoutAnno))
.addAttribute(EnhancedType.documentOf(InnerBean.class,
    innerBeanStaticTableSchema,
    b -> b.ignoreNulls(true)),
    a -> a.name("innerBeanWithIgnoreNullsAnno")
    .getter(MyBean::getInnerBeanWithIgnoreNullsAnno)
    .setter(MyBean::setInnerBeanWithIgnoreNullsAnno))
.build();
}
```

Work with JSON documents with the Enhanced Document API for DynamoDB

The [Enhanced Document API](#) for AWS SDK for Java 2.x is designed to work with document-oriented data that has no fixed schema. However, it also lets you use custom classes to map individual attributes.

The Enhanced Document API is the successor to the [Document API](#) of the AWS SDK for Java v1.x.

Contents

- [Get started using the Enhanced Document API](#)
 - [Create a DocumentTableSchema and a DynamoDbTable](#)
- [Build enhanced documents](#)
 - [Build from a JSON string](#)
 - [Build from individual elements](#)
- [Perform CRUD operations](#)
- [Access enhanced document attributes as custom objects](#)
- [Use an EnhancedDocument without DynamoDB](#)

Get started using the Enhanced Document API

The Enhanced Document API requires the same [dependencies](#) that are needed for the DynamoDB Enhanced Client API. It also requires a [DynamoDbEnhancedClient instance](#) as shown at the start of this topic.

Because the Enhanced Document API was released with version 2.20.3 of the AWS SDK for Java 2.x, you need that version or greater.

Create a DocumentTableSchema and a DynamoDbTable

To invoke commands against a DynamoDB table using the Enhanced Document API, associate the table with a client-side [DynamoDbTable<EnhancedDocument>](#) resource object.

The enhanced client's `table()` method creates a `DynamoDbTable<EnhancedDocument>` instance and requires parameters for the DynamoDB table name and a `DocumentTableSchema`.

The builder for a [DocumentTableSchema](#) requires a primary index key and one or more attribute converter providers. The `AttributeConverterProvider.defaultProvider()` method provides converters for [default types](#). It should be specified even if you provide a custom attribute converter provider. You can add an optional secondary index key to the builder.

The following code snippet shows the code that generates the client-side representation of a DynamoDB person table that stores schemaless `EnhancedDocument` objects.

```
DynamoDbTable<EnhancedDocument> documentDynamoDbTable =
    enhancedClient.table("person",
        TableSchema.documentSchemaBuilder()
            // Specify the primary key attributes.

        .addIndexPartitionKey(TableMetadata.primaryIndexName(),"id", AttributeValueType.S)
            .addIndexSortKey(TableMetadata.primaryIndexName(),
"lastName", AttributeValueType.S)
            // Specify attribute converter providers. Minimally add the
default one.

        .attributeConverterProviders(AttributeConverterProvider.defaultProvider())
            .build());

// Call documentTable.createTable() if "person" does not exist in DynamoDB.
// createTable() should be called only one time.
```

The following shows the JSON representation of a person object that is used throughout this section.

JSON person object

```
{
  "id": 1,
  "firstName": "Richard",
  "lastName": "Roe",
  "age": 25,
  "addresses":
  {
    "home": {
      "zipCode": "00000",
      "city": "Any Town",
      "state": "FL",
      "street": "123 Any Street"
    },
    "work": {
      "zipCode": "00001",
      "city": "Anywhere",
      "state": "FL",
      "street": "100 Main Street"
    }
  },
  "hobbies": [
    "Hobby 1",
    "Hobby 2"
  ],
  "phoneNumbers": [
    {
      "type": "Home",
      "number": "555-0100"
    },
    {
      "type": "Work",
      "number": "555-0119"
    }
  ]
}
```

Build enhanced documents

An [EnhancedDocument](#) represents a document-type object that has complex structure with nested attributes. An `EnhancedDocument` requires top-level attributes that match the primary key attributes specified for the `DocumentTableSchema`. The remaining content is arbitrary and can consist of top-level attributes and also deeply nested attributes.

You create an `EnhancedDocument` instance by using a builder that provides several ways to add elements.

Build from a JSON string

With a JSON string, you can build an `EnhancedDocument` in one method call. The following snippet creates an `EnhancedDocument` from a JSON string returned by the `jsonPerson()` helper method. The `jsonPerson()` method returns the JSON string version of the [person object](#) shown previously.

```
EnhancedDocument document =
    EnhancedDocument.builder()
        .json( jsonPerson() )
        .build();
```

Build from individual elements

Alternatively, you can build an `EnhancedDocument` instance from individual components using type-safe methods of the builder.

The following example builds a person enhanced document similar to the enhanced document that is built from the JSON string in the previous example.

```
    /* Define the shape of an address map whose JSON representation looks like the
    following.
       Use 'addressMapEnhancedType' in the following EnhancedDocument.builder() to
    simplify the code.
       "home": {
         "zipCode": "00000",
         "city": "Any Town",
         "state": "FL",
         "street": "123 Any Street"
       }*/
    EnhancedType<Map<String, String>> addressMapEnhancedType =
```

```

        EnhancedType.mapOf(EnhancedType.of(String.class),
EnhancedType.of(String.class));

    // Use the builder's typesafe methods to add elements to the enhanced
document.
    EnhancedDocument personDocument = EnhancedDocument.builder()
        .putNumber("id", 50)
        .putString("firstName", "Shirley")
        .putString("lastName", "Rodriguez")
        .putNumber("age", 53)
        .putNull("nullAttribute")
        .putJson("phoneNumbers", phoneNumbersJSONString())
        /* Add the map of addresses whose JSON representation looks like the
following.
        {
            "home": {
                "zipCode": "00000",
                "city": "Any Town",
                "state": "FL",
                "street": "123 Any Street"
            }
        } */
        .putMap("addresses", getAddresses(), EnhancedType.of(String.class),
addressMapEnhancedType)
        .putList("hobbies", List.of("Theater", "Golf"),
EnhancedType.of(String.class))
        .build();

```

Helper methods

```

private static String phoneNumbersJSONString() {
    return "[" +
        "    {" +
        "        \"type\": \"Home\",\" +
        "        \"number\": \"555-0140\"\" +
        "    },\" +
        "    {" +
        "        \"type\": \"Work\",\" +
        "        \"number\": \"555-0155\"\" +
        "    }\" +
        " ]";
}

```

```
private static Map<String, Map<String, String>> getAddresses() {
    return Map.of(
        "home", Map.of(
            "zipCode", "00002",
            "city", "Any Town",
            "state", "ME",
            "street", "123 Any Street"));
}
```

Perform CRUD operations

After you define an `EnhancedDocument` instance, you can save it to a DynamoDB table. The following code snippet uses the [personDocument](#) that was created from individual elements.

```
documentDynamoDbTable.putItem(personDocument);
```

After you read an enhanced document instance from DynamoDB, you can extract the individual attribute values using getters as shown in the following code snippet that access the data saved from the `personDocument`. Alternatively, you can extract the complete content to a JSON string as shown in the last part of the example code.

```
// Read the item.
EnhancedDocument personDocFromDb =
documentDynamoDbTable.getItem(Key.builder().partitionValue(50).build());

// Access top-level attributes.
logger.info("Name: {} {}", personDocFromDb.getString("firstName"),
personDocFromDb.getString("lastName"));
// Name: Shirley Rodriguez

// Typesafe access of a deeply nested attribute. The addressMapEnhancedType
shown previously defines the shape of an addresses map.
Map<String, Map<String, String>> addresses =
personDocFromDb.getMap("addresses", EnhancedType.of(String.class),
addressMapEnhancedType);
addresses.keySet().forEach(k -> logger.info(addresses.get(k).toString()));
// {zipCode=00002, city=Any Town, street=123 Any Street, state=ME}

// Alternatively, work with AttributeValue types checking along the way for
deeply nested attributes.
```

```

    Map<String, AttributeValue> addressesMap =
personDocFromDb.getMapOfUnknownType("addresses");
    addressesMap.keySet().forEach((String k) -> {
        logger.info("Looking at data for [{}] address", k);
        // Looking at data for [home] address
        AttributeValue value = addressesMap.get(k);
        AttributeValue cityValue = value.m().get("city");
        if (cityValue != null) {
            logger.info(cityValue.s());
            // Any Town
        }
    });

    List<AttributeValue> phoneNumbers =
personDocFromDb.getListOfUnknownType("phoneNumbers");
    phoneNumbers.forEach((AttributeValue av) -> {
        if (av.hasM()) {
            AttributeValue type = av.m().get("type");
            if (type.s() != null) {
                logger.info("Type of phone: {}", type.s());
                // Type of phone: Home
                // Type of phone: Work
            }
        }
    });

    String jsonPerson = personDocFromDb.toJson();
    logger.info(jsonPerson);
    // {"firstName":"Shirley","lastName":"Rodriguez","addresses":
{"home":{"zipCode":"00002","city":"Any Town","street":"123 Any
Street","state":"ME"}}, "hobbies":["Theater","Golf"],
    //      "id":50,"nullAttribute":null,"age":53,"phoneNumbers":
[{"number":"555-0140","type":"Home"}, {"number":"555-0155","type":"Work"}]}

```

EnhancedDocument instances can be used with any method of [DynamoDbTable](#) or [DynamoDbEnhancedClient](#) in place of mapped data classes.

Access enhanced document attributes as custom objects

In addition to providing an API to read and write attributes with schemaless structures, the Enhanced Document API lets you convert attributes to and from instances of custom classes.

The Enhanced Document API uses `AttributeConverterProviders` and `AttributeConverters` that were shown in the [control attribute conversion](#) section as part of the DynamoDB Enhanced Client API.

In the following example, we use a `CustomAttributeConverterProvider` with its nested `AddressConverter` class to convert `Address` objects.

This example shows that you can mix data from classes and also data from structures that are built as needed. This example also shows that custom classes can be used at any level of a nested structure. The `Address` objects in this example are values used in a map.

```
public static void attributeToAddressClassMappingExample(DynamoDbEnhancedClient
enhancedClient, DynamoDbClient standardClient) {
    String tableName = "customer";

    // Define the DynamoDbTable for an enhanced document.
    // The schema builder provides methods for attribute converter providers and
keys.
    DynamoDbTable<EnhancedDocument> documentDynamoDbTable =
enhancedClient.table(tableName,
        DocumentTableSchema.builder()
            // Add the CustomAttributeConverterProvider along with the
default when you build the table schema.
            .attributeConverterProviders(
                List.of(
                    new CustomAttributeConverterProvider(),
                    AttributeConverterProvider.defaultProvider()))
            .addIndexPartitionKey(TableMetadata.primaryIndexName(), "id",
AttributeValueType.N)
            .addIndexSortKey(TableMetadata.primaryIndexName(), "lastName",
AttributeValueType.S)
            .build());
    // Create the DynamoDB table if needed.
    documentDynamoDbTable.createTable();
    waitForTableCreation(tableName, standardClient);

    // The getAddressessForCustomMappingExample() helper method that provides
'addresses' shows the use of a custom Address class
    // rather than using a Map<String, Map<String, String> to hold the address
data.
    Map<String, Address> addresses = getAddressessForCustomMappingExample();
```

```

    // Build an EnhancedDocument instance to save an item with a mix of structures
    defined as needed and static classes.
    EnhancedDocument personDocument = EnhancedDocument.builder()
        .putNumber("id", 50)
        .putString("firstName", "Shirley")
        .putString("lastName", "Rodriguez")
        .putNumber("age", 53)
        .putNull("nullAttribute")
        .putJson("phoneNumbers", phoneNumbersJSONString())
    // Note the use of 'EnhancedType.of(Address.class)' instead of the more
generic
        // 'EnhancedType.mapOf(EnhancedType.of(String.class),
EnhancedType.of(String.class))' that was used in a previous example.
        .putMap("addresses", addresses, EnhancedType.of(String.class),
EnhancedType.of(Address.class))
        .putList("hobbies", List.of("Hobby 1", "Hobby 2"),
EnhancedType.of(String.class))
        .build();
    // Save the item to DynamoDB.
    documentDynamoDbTable.putItem(personDocument);

    // Retrieve the item just saved.
    EnhancedDocument srPerson =
documentDynamoDbTable.getItem(Key.builder().partitionValue(50).sortValue("Rodriguez").build())

    // Access the addresses attribute.
    Map<String, Address> srAddresses = srPerson.get("addresses",
        EnhancedType.mapOf(EnhancedType.of(String.class),
EnhancedType.of(Address.class)));

    srAddresses.keySet().forEach(k -> logger.info(addresses.get(k).toString()));

    documentDynamoDbTable.deleteTable();

// The content logged to the console shows that the saved maps were converted to
Address instances.
Address{street='123 Main Street', city='Any Town', state='NC', zipCode='00000'}
Address{street='100 Any Street', city='Any Town', state='NC', zipCode='00000'}

```

CustomAttributeConverterProvider code

```
public class CustomAttributeConverterProvider implements AttributeConverterProvider {
```

```

private final Map<EnhancedType<?>, AttributeConverter<?>> converterCache =
ImmutableMap.of(
    // 1. Add AddressConverter to the internal cache.
    EnhancedType.of(Address.class), new AddressConverter());

public static CustomAttributeConverterProvider create() {
    return new CustomAttributeConverterProvider();
}

// 2. The enhanced client queries the provider for attribute converters if it
// encounters a type that it does not know how to convert.
@SuppressWarnings("unchecked")
@Override
public <T> AttributeConverter<T> converterFor(EnhancedType<T> enhancedType) {
    return (AttributeConverter<T>) converterCache.get(enhancedType);
}

// 3. Custom attribute converter
private class AddressConverter implements AttributeConverter<Address> {
    // 4. Transform an Address object into a DynamoDB map.
    @Override
    public AttributeValue transformFrom(Address address) {

        Map<String, AttributeValue> attributeValueMap = Map.of(
            "street", AttributeValue.fromS(address.getStreet()),
            "city", AttributeValue.fromS(address.getCity()),
            "state", AttributeValue.fromS(address.getState()),
            "zipCode", AttributeValue.fromS(address.getZipCode()));

        return AttributeValue.fromM(attributeValueMap);
    }

    // 5. Transform the DynamoDB map attribute to an Address object.
    @Override
    public Address transformTo(AttributeValue attributeValue) {
        Map<String, AttributeValue> m = attributeValue.m();
        Address address = new Address();
        address.setStreet(m.get("street").s());
        address.setCity(m.get("city").s());
        address.setState(m.get("state").s());
        address.setZipCode(m.get("zipCode").s());

        return address;
    }
}

```

```
@Override
public EnhancedType<Address> type() {
    return EnhancedType.of(Address.class);
}

@Override
public AttributeValueType attributeValueType() {
    return AttributeValueType.M;
}
}
```

Address class

```
public class Address {
    private String street;
    private String city;
    private String state;
    private String zipCode;

    public Address() {
    }

    public String getStreet() {
        return this.street;
    }

    public String getCity() {
        return this.city;
    }

    public String getState() {
        return this.state;
    }

    public String getZipCode() {
        return this.zipCode;
    }

    public void setStreet(String street) {
        this.street = street;
    }
}
```

```
public void setCity(String city) {
    this.city = city;
}

public void setState(String state) {
    this.state = state;
}

public void setZipCode(String zipCode) {
    this.zipCode = zipCode;
}
}
```

Helper method that provides addresses

The following helper method provides the map that use custom `Address` instances for values rather than generic `Map<String, String>` instances for values.

```
private static Map<String, Address> getAddressesForCustomMappingExample() {
    Address homeAddress = new Address();
    homeAddress.setStreet("100 Any Street");
    homeAddress.setCity("Any Town");
    homeAddress.setState("NC");
    homeAddress.setZipCode("00000");

    Address workAddress = new Address();
    workAddress.setStreet("123 Main Street");
    workAddress.setCity("Any Town");
    workAddress.setState("NC");
    workAddress.setZipCode("00000");

    return Map.of("home", homeAddress,
                 "work", workAddress);
}
```

Use an `EnhancedDocument` without `DynamoDB`

Although you usually use an instance of an `EnhancedDocument` to read and write document-type `DynamoDB` items, it can also be used independently of `DynamoDB`.

You can use `EnhancedDocuments` for their ability to convert between JSON strings or custom objects to low-level maps of `AttributeValues` as shown in the following example.

```
public static void conversionWithoutDynamoDbExample() {
    Address address = new Address();
    address.setCity("my city");
    address.setState("my state");
    address.setStreet("my street");
    address.setZipCode("00000");

    // Build an EnhancedDocument instance for its conversion functionality alone.
    EnhancedDocument addressEnhancedDoc = EnhancedDocument.builder()
        // Important: You must specify attribute converter providers when you
    build an EnhancedDocument instance not used with a DynamoDB table.
        .attributeConverterProviders(new CustomAttributeConverterProvider(),
    DefaultAttributeConverterProvider.create())
        .put("addressDoc", address, Address.class)
        .build();

    // Convert address to a low-level item representation.
    final Map<String, AttributeValue> addressAsAttributeMap =
    addressEnhancedDoc.getMapOfUnknownType("addressDoc");
    logger.info("addressAsAttributeMap: {}", addressAsAttributeMap.toString());

    // Convert address to a JSON string.
    String addressAsJsonString = addressEnhancedDoc.getJson("addressDoc");
    logger.info("addressAsJsonString: {}", addressAsJsonString);
    // Convert addressEnhancedDoc back to an Address instance.
    Address addressConverted = addressEnhancedDoc.get("addressDoc",
    Address.class);
    logger.info("addressConverted: {}", addressConverted.toString());
}

/* Console output:
    addressAsAttributeMap: {zipCode=AttributeValue(S=00000),
state=AttributeValue(S=my state), street=AttributeValue(S=my street),
city=AttributeValue(S=my city)}
    addressAsJsonString: {"zipCode":"00000","state":"my state","street":"my
street","city":"my city"}
    addressConverted: Address{street='my street', city='my city', state='my
state', zipCode='00000'}
*/
```

Note

When you use an enhanced document independent of a DynamoDB table, make sure you explicitly set attribute converter providers on the builder.

In contrast, the document table schema supplies the converter providers when an enhanced document is used with a DynamoDB table.

Use extensions

The DynamoDB Enhanced Client API supports plugin extensions that provide functionality beyond mapping operations. Extensions have two hook methods, `beforeWrite()` and `afterRead()`. `beforeWrite()` modifies a write operation before it happens, and the `afterRead()` method modifies the results of a read operation after it happens. Because some operations (such as item updates) perform both a write and then a read, both hook methods are called.

Extensions are loaded in the order that they are specified in the enhanced client builder. The load order can be important because one extension can act on values that have been transformed by a previous extension.

The enhanced client API comes with a set of plugin extensions that are located in the [extensions](#) package. By default, the enhanced client loads the [VersionedRecordExtension](#) and the [AtomicCounterExtension](#). You can override the default behavior with the enhance client builder and load any extension. You can also specify none if you don't want the default extensions.

If you load your own extensions, the enhanced client doesn't load any default extensions. If you want the behavior provided by either default extension, you need to explicitly add it to the list of extensions.

In the following example, a custom extension named `verifyChecksumExtension` is loaded after the `VersionedRecordExtension`, which is usually loaded by default by itself. The `AtomicCounterExtension` is not loaded in this example.

```
DynamoDbEnhancedClientExtension versionedRecordExtension =
    VersionedRecordExtension.builder().build();

DynamoDbEnhancedClient enhancedClient =
    DynamoDbEnhancedClient.builder()
        .dynamoDbClient(dynamoDbClient)
```

```

        .extensions(versionedRecordExtension,
verifyChecksumExtension)
        .build();

```

VersionedRecordExtension

The `VersionedRecordExtension` is loaded by default and will increment and track an item version number as items are written to the database. A condition will be added to every write that causes the write to fail if the version number of the actual persisted item doesn't match the value that the application last read. This behavior effectively provides optimistic locking for item updates. If another process updates an item between the time the first process has read the item and is writing an update to it, the write will fail.

To specify which attribute to use to track the item version number, tag a numeric attribute in the table schema.

The following snippet specifies that the `version` attribute should hold the item version number.

```

@DynamoDbVersionAttribute
public Integer getVersion() {...};
public void setVersion(Integer version) {...};

```

The equivalent static table schema approach is shown in the following snippet.

```

.addAttribute(Integer.class, a -> a.name("version")
                .getter(Customer::getVersion)
                .setter(Customer::setVersion)
                // Apply the 'version' tag to the attribute.

.tags(VersionedRecordExtension.AttributeTags.versionAttribute())

```

AtomicCounterExtension

The `AtomicCounterExtension` is loaded by default and increments a tagged numerical attribute each time a record is written to the database. Start and increment values can be specified. If no values are specified, the start value is set to 0 and the attribute's value increments by 1.

To specify which attribute is a counter, tag an attribute of type `Long` in the table schema.

The following snippet shows the use of the default start and increment values for the `counter` attribute.

```
@DynamoDbAtomicCounter
public Long getCounter() {...};
public void setCounter(Long counter) {...};
```

The static table schema approach is shown in the following snippet. The atomic counter extension uses a start value of 10 and increments the value by 5 each time the record is written.

```
.addAttribute(Integer.class, a -> a.name("counter")
    .getter(Customer::getCounter)
    .setter(Customer::setCounter)
    // Apply the 'atomicCounter' tag to the
attribute with start and increment values.
    .tags(StaticAttributeTags.atomicCounter(10L,
5L))
```

AutoGeneratedTimestampRecordExtension

The `AutoGeneratedTimestampRecordExtension` automatically updates tagged attributes of type [Instant](#) with a current timestamp every time the item is successfully written to the database.

This extension is not loaded by default. Therefore, you need to specify it as a custom extension when you build the enhanced client as shown in the first example in this topic.

To specify which attribute to update with the current timestamp, tag the `Instant` attribute in the table schema.

The `lastUpdate` attribute is the target of the extensions behavior in the following snippet. Note the requirement that the attribute must be an `Instant` type.

```
@DynamoDbAutoGeneratedTimestampAttribute
public Instant getLastUpdate() {...}
public void setLastUpdate(Instant lastUpdate) {...}
```

The equivalent static table schema approach is shown in the following snippet.

```
.addAttribute(Instant.class, a -> a.name("lastUpdate")
    .getter(Customer::getLastUpdate)
    .setter(Customer::setLastUpdate)
    // Applying the 'autoGeneratedTimestamp' tag to
the attribute.
```

```
.tags(AutoGeneratedTimestampRecordExtension.AttributeTags.autoGeneratedTimestampAttribute())
```

AutoGeneratedUuidExtension

You can generate a unique UUID (Universally Unique Identifier) for an attribute when a new record is written to the database by using the [AutoGeneratedUuidExtension](#). The Java JDK [UUID.randomUUID\(\)](#) method generates the value and you apply the extension to a attributes of type `java.lang.String`.

Since the Java SDK does not load this extension by default, you need to specify it as a custom extension when you build the enhanced client as shown in the [first example in this topic](#).

The `uniqueId` attribute is the target of the extension's behavior in the following snippet.

```
@AutoGeneratedUuidExtension
public String getUniqueId() {...}
public void setUniqueId(String uniqueId) {...}
```

The equivalent static table schema approach is shown in the following snippet.

```
.addAttribute(String.class, a -> a.name("uniqueId")
                .getter(Customer::getUniqueId)
                .setter(Customer::setUniqueId)
                // Applying the 'autoGeneratedUuid' tag to the
attribute.

.tags(AutoGeneratedUuidExtension.AttributeTags.autoGeneratedUuidAttribute())
```

If you want the extension to populate the UUID only for `putItem` methods and not for `updateItem` methods, add the [update behavior](#) annotation as shown in the following snippet.

```
@AutoGeneratedUuidExtension
@DynamoDbUpdateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS)
public String getUniqueId() {...}
public void setUniqueId(String uniqueId) {...}
```

If you use the static table schema approach, use the following equivalent code.

```
.addAttribute(String.class, a -> a.name("uniqueId"))
```

```

        .getter(Customer::getUniqueId)
        .setter(Customer::setUniqueId)
        // Applying the 'autoGeneratedUuid' tag to the
attribute.

.tags(AutoGeneratedUuidExtension.AttributeTags.autoGeneratedUuidAttribute(),
StaticAttributeTags.updateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS))

```

Custom extensions

The following custom extension class shows a `beforeWrite()` method that uses an update expression. After comment line 2, we create a `SetAction` to set the `registrationDate` attribute if the item in the database doesn't already have a `registrationDate` attribute. Whenever a `Customer` object is updated, the extension makes sure that a `registrationDate` is set.

```

public final class CustomExtension implements DynamoDbEnhancedClientExtension {

    // 1. In a custom extension, use an UpdateExpression to define what action to take
before
//    an item is updated.
@Override
public WriteModification beforeWrite(DynamoDbExtensionContext.BeforeWrite context)
{
    if ( context.operationContext().tableName().equals("Customer")
        && context.operationName().equals(OperationName.UPDATE_ITEM)) {
        return WriteModification.builder()
            .updateExpression(createUpdateExpression())
            .build();
    }
    return WriteModification.builder().build(); // Return an "empty"
WriteModification instance if the extension should not be applied.
// In this case, if the code is
not updating an item on the Customer table.
}

private static UpdateExpression createUpdateExpression() {

    // 2. Use a SetAction, a subclass of UpdateAction, to provide the values in the
update.
    SetAction setAction =
        SetAction.builder()
            .path("registrationDate")

```

```

        .value("if_not_exists(registrationDate, :regValue)")
        .putExpressionValue(":regValue",
AttributeValue.fromS(Instant.now().toString()))
        .build();
// 3. Build the UpdateExpression with one or more UpdateAction.
return UpdateExpression.builder()
    .addAction(setAction)
    .build();
    }
}

```

Use the DynamoDB Enhanced Client API asynchronously

If your application requires non-blocking, asynchronous calls to DynamoDB, you can use the [DynamoDbEnhancedAsyncClient](#). It's similar to the synchronous implementation but with the following key differences:

1. When you build the `DynamoDbEnhancedAsyncClient`, you must provide the asynchronous version of the standard client, `DynamoDbAsyncClient`, as shown in the following snippet.

```

DynamoDbEnhancedAsyncClient enhancedClient =
    DynamoDbEnhancedAsyncClient.builder()
        .dynamoDbClient(dynamoDbAsyncClient)
        .build();

```

2. Methods that return a single data object return a `CompletableFuture` of the result instead of only the result. Your application can then do other work without having to block on the result. The following snippet shows the asynchronous `getItem()` method.

```

CompletableFuture<Customer> result = customerDynamoDbTable.getItem(customer);
// Perform other work here.
return result.join(); // Now block and wait for the result.

```

3. Methods that return paginated lists of results return an [SdkPublisher](#) instead of an [SdkIterable](#) that the synchronous `DynamoDbEnhancedClient` returns for the same methods. Your application can then subscribe a handler to that publisher to deal with the results asynchronously without having to block.

```

PagePublisher<Customer> results = customerDynamoDbTable.query(r ->
    r.queryConditional(keyEqualTo(k -> k.partitionValue("Smith"))));
results.subscribe(myCustomerResultsProcessor);

```

```
// Perform other work and let the processor handle the results asynchronously.
```

For a more complete example of working with the `SdkPublisher` API, see [the example](#) in the section that discusses the `asynchronousScan()` method of this guide.

Data class annotations

The following table lists the annotations that can be used on data classes and provides links to information and examples in this guide. The table is sorted in ascending alphabetical order by annotation name.

Data class annotations used in this guide

Annotation name	Annotation applies to ¹	What it does	Where it is shown in this guide
<code>DynamoDbAtomicCounter</code>	attribute ²	Increments a tagged numerical attribute each time a record is written to the database.	Introduction and discussion.
<code>DynamoDbAttribute</code>	attribute	Defines or renames a bean property that is mapped to a DynamoDB table attribute.	<ul style="list-style-type: none"> • Initial discussion. • Get started section —see Note. • In MovieActor class In Query method examples.
<code>DynamoDbAutoGeneratedTimestampAttribute</code>	attribute	Updates a tagged attribute with a current timestamp every time the item is successfully written to the database	Introduction and discussion.
<code>DynamoDbAutoGeneratedUuid</code>	attribute	Generate a unique UUID (Universally	Introduction and discussion.

Annotation name	Annotation applies to ¹	What it does	Where it is shown in this guide
		Unique Identifier) for an attribute when a new record is written to the database.	
DynamoDbBean	class	Marks a data class as mappable to a table schema.	First use on the Customer class in the Get started section. Several usages appear throughout the guide.
DynamoDbConvertedBy	attribute	Associates a custom Attribute Converter with the annotated attribute.	Initial discussion and example.
DynamoDbFlatten	attribute	Flattens all the attributes of a separate DynamoDB data class and adds them as top-level attributes to the record that is read and written to the database.	<ul style="list-style-type: none"> • Initial discussion. • Implications for other code.
DynamoDbIgnore	attribute	Results in the attribute remaining unmapped.	<ul style="list-style-type: none"> • Initial discussion. • Use in the ProductCatalog class.

Annotation name	Annotation applies to ¹	What it does	Where it is shown in this guide
DynamoDbIgnoreNulls	attribute	Prevents saving null attributes of nested DynamoDb objects.	Discussion and examples.
DynamoDbImmutable	class	Marks an immutable data class as mappable to a table schema.	<ul style="list-style-type: none"> • Introduction to the annotation. • Use in the ProductCatalog class. • Use with Lombok.
DynamoDbPartitionKey	attribute	Marks an attribute as the primary partition key (hash key) of the DynamoDb table.	<ul style="list-style-type: none"> • Initial usage on the Customer class in the Get started section. • With Lombok.
DynamoDbPreserveEmptyObject	attribute	Specifies that if no data is present for the object mapped to the annotated attribute, the object should be initialized with all null fields.	Discussion and examples.
DynamoDbSecondaryPartitionKey	attribute	Marks an attribute as a partition key for a global secondary index.	<ul style="list-style-type: none"> • Use in secondary indices and example. • In Query method examples. • In Lombok example • With immutable classes.

Annotation name	Annotation applies to ¹	What it does	Where it is shown in this guide
DynamoDbSecondarySortKey	attribute	Marks an attribute as an optional sort key for a global or local secondary index.	<ul style="list-style-type: none"> • Use in secondary indices and example. • In Query method examples. • In Lombok example. • With immutable classes.
DynamoDbSortKey	attribute	Marks an attribute as the optional primary sort key (range key).	<ul style="list-style-type: none"> • Get started section on Customer class. • With immutable classes. • In Lombok example. • In Query method examples.
DynamoDbUpdateBehavior	attribute	Specifies the behavior when this attribute is updated as part of an 'update' operation such as UpdateItem.	Introduction and example.
DynamoDbVersionAttribute	attribute	Increments an item version number.	Introduction and discussion.

¹You can apply an attribute-level annotations to the getter or setter, but not both. This guide shows annotations on getters.

²The term `property` is normally used for a value encapsulated in a JavaBean data class. However, this guide uses the term `attribute` instead, to be consistent with the terminology used by DynamoDB.

Work with Amazon EC2

This section provides examples of programming [Amazon EC2](#) that use the AWS SDK for Java 2.x.

Topics

- [Manage Amazon EC2 instances](#)
- [Use AWS Regions and Availability Zones](#)
- [Work with security groups in Amazon EC2](#)
- [Work with Amazon EC2 instance metadata](#)

Manage Amazon EC2 instances

Create an instance

Create a new Amazon EC2 instance by calling the [Ec2Client](#)'s [runInstances](#) method, providing it with a [RunInstancesRequest](#) containing the [Amazon Machine Image \(AMI\)](#) to use and an [instance type](#).

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.InstanceType;
import software.amazon.awssdk.services.ec2.model.RunInstancesRequest;
import software.amazon.awssdk.services.ec2.model.RunInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Tag;
import software.amazon.awssdk.services.ec2.model.CreateTagsRequest;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```
public static String createEC2Instance(Ec2Client ec2, String name, String amiId ) {
    RunInstancesRequest runRequest = RunInstancesRequest.builder()
```

```
        .imageId(amiId)
        .instanceType(InstanceType.T1_MICRO)
        .maxCount(1)
        .minCount(1)
        .build();

RunInstancesResponse response = ec2.runInstances(runRequest);
String instanceId = response.instances().get(0).instanceId();

Tag tag = Tag.builder()
    .key("Name")
    .value(name)
    .build();

CreateTagsRequest tagRequest = CreateTagsRequest.builder()
    .resources(instanceId)
    .tags(tag)
    .build();

try {
    ec2.createTags(tagRequest);
    System.out.printf(
        "Successfully started EC2 Instance %s based on AMI %s",
        instanceId, amiId);

    return instanceId;

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return "";
}
```

See the [complete example](#) on GitHub.

Start an instance

To start an Amazon EC2 instance, call the `Ec2Client`'s [startInstances](#) method, providing it with a [StartInstancesRequest](#) containing the ID of the instance to start.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.StartInstancesRequest;
import software.amazon.awssdk.services.ec2.model.StopInstancesRequest;
```

Code

```
public static void startInstance(Ec2Client ec2, String instanceId) {

    StartInstancesRequest request = StartInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    ec2.startInstances(request);
    System.out.printf("Successfully started instance %s", instanceId);
}
```

See the [complete example](#) on GitHub.

Stop an instance

To stop an Amazon EC2 instance, call the `Ec2Client`'s [stopInstances](#) method, providing it with a [StopInstancesRequest](#) containing the ID of the instance to stop.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.StartInstancesRequest;
import software.amazon.awssdk.services.ec2.model.StopInstancesRequest;
```

Code

```
public static void stopInstance(Ec2Client ec2, String instanceId) {

    StopInstancesRequest request = StopInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    ec2.stopInstances(request);
    System.out.printf("Successfully stopped instance %s", instanceId);
}
```

```
}
```

See the [complete example](#) on GitHub.

Reboot an instance

To reboot an Amazon EC2 instance, call the `Ec2Client`'s [rebootInstances](#) method, providing it with a [RebootInstancesRequest](#) containing the ID of the instance to reboot.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.RebootInstancesRequest;
```

Code

```
public static void rebootEC2Instance(Ec2Client ec2, String instanceId) {
    try {
        RebootInstancesRequest request = RebootInstancesRequest.builder()
            .instanceIds(instanceId)
            .build();

        ec2.rebootInstances(request);
        System.out.printf(
            "Successfully rebooted instance %s", instanceId);
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Describe instances

To list your instances, create a [DescribeInstancesRequest](#) and call the `Ec2Client`'s [describeInstances](#) method. It will return a [DescribeInstancesResponse](#) object that you can use to list the Amazon EC2 instances for your account and region.

Instances are grouped by *reservation*. Each reservation corresponds to the call to `startInstances` that launched the instance. To list your instances, you must first call the `DescribeInstancesResponse` class' `reservations` method, and then call `instances` on each returned [Reservation](#) object.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesRequest;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Instance;
import software.amazon.awssdk.services.ec2.model.Reservation;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```
public static void describeEC2Instances( Ec2Client ec2){

    String nextToken = null;

    try {

        do {

            DescribeInstancesRequest request =
DescribeInstancesRequest.builder().maxResults(6).nextToken(nextToken).build();
            DescribeInstancesResponse response = ec2.describeInstances(request);

            for (Reservation reservation : response.reservations()) {
                for (Instance instance : reservation.instances()) {
                    System.out.println("Instance Id is " + instance.instanceId());
                    System.out.println("Image id is "+ instance.imageId());
                    System.out.println("Instance type is "+
instance.instanceType());
                    System.out.println("Instance state name is "+
instance.state().name());
                    System.out.println("monitoring information is "+
instance.monitoring().state());

                }
            }

            nextToken = response.nextToken();
        } while (nextToken != null);
    }
}
```

```
    } catch (Ec2Exception e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

Results are paged; you can get further results by passing the value returned from the result object's `nextToken` method to a new request object's `nextToken` method, then using the new request object in your next call to `describeInstances`.

See the [complete example](#) on GitHub.

Monitor an instance

You can monitor various aspects of your Amazon EC2 instances, such as CPU and network utilization, available memory, and disk space remaining. To learn more about instance monitoring, see [Monitoring Amazon EC2](#) in the Amazon EC2 User Guide for Linux Instances.

To start monitoring an instance, you must create a [MonitorInstancesRequest](#) with the ID of the instance to monitor, and pass it to the `Ec2Client`'s [monitorInstances](#) method.

Imports

```
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.ec2.Ec2Client;  
import software.amazon.awssdk.services.ec2.model.MonitorInstancesRequest;  
import software.amazon.awssdk.services.ec2.model.UnmonitorInstancesRequest;
```

Code

```
public static void monitorInstance( Ec2Client ec2, String instanceId) {  
  
    MonitorInstancesRequest request = MonitorInstancesRequest.builder()  
        .instanceIds(instanceId).build();  
  
    ec2.monitorInstances(request);  
    System.out.printf(  
        "Successfully enabled monitoring for instance %s",  
        instanceId);  
}
```

See the [complete example](#) on GitHub.

Stop instance monitoring

To stop monitoring an instance, create an [UnmonitorInstancesRequest](#) with the ID of the instance to stop monitoring, and pass it to the `Ec2Client`'s [unmonitorInstances](#) method.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.MonitorInstancesRequest;
import software.amazon.awssdk.services.ec2.model.UnmonitorInstancesRequest;
```

Code

```
public static void unmonitorInstance(Ec2Client ec2, String instanceId) {
    UnmonitorInstancesRequest request = UnmonitorInstancesRequest.builder()
        .instanceIds(instanceId).build();

    ec2.unmonitorInstances(request);

    System.out.printf(
        "Successfully disabled monitoring for instance %s",
        instanceId);
}
```

See the [complete example](#) on GitHub.

Use AWS Regions and Availability Zones

Describe Regions

To list the Regions available to your account, call the `Ec2Client`'s `describeRegions` method. It returns a [DescribeRegionsResponse](#). Call the returned object's `regions` method to get a list of [Region](#) objects that represent each Region.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import java.util.concurrent.CompletableFuture;
```

Code

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeRegionsAndZones {
    public static void main(String[] args) {
        Ec2AsyncClient ec2AsyncClient = Ec2AsyncClient.builder()
            .region(Region.US_EAST_1)
            .build();

        try {
            CompletableFuture<Void> future =
describeEC2RegionsAndZonesAsync(ec2AsyncClient);
            future.join(); // Wait for both async operations to complete.
        } catch (RuntimeException rte) {
```

```

        System.err.println("An exception occurred: " + (rte.getCause() != null ?
rte.getCause().getMessage() : rte.getMessage()));
    }
}

/**
 * Asynchronously describes the EC2 regions and availability zones.
 *
 * @param ec2AsyncClient the EC2 async client used to make the API calls
 * @return a {@link CompletableFuture} that completes when both the region and
availability zone descriptions are complete
 */
public static CompletableFuture<Void>
describeEC2RegionsAndZonesAsync(Ec2AsyncClient ec2AsyncClient) {
    // Initiate the asynchronous request to describe regions
    CompletableFuture<DescribeRegionsResponse> regionsResponse =
ec2AsyncClient.describeRegions();

    // Handle the response or exception for regions
    CompletableFuture<DescribeRegionsResponse> regionsFuture =
regionsResponse.whenComplete((regionsResp, ex) -> {
        if (ex != null) {
            // Handle the exception by throwing a RuntimeException
            throw new RuntimeException("Failed to describe EC2 regions.", ex);
        } else if (regionsResp == null || regionsResp.regions().isEmpty()) {
            // Throw an exception if the response is null or the result is empty
            throw new RuntimeException("No EC2 regions found.");
        } else {
            // Process the response if no exception occurred and the result is not
empty
            regionsResp.regions().forEach(region -> {
                System.out.printf(
                    "Found Region %s with endpoint %s%n",
                    region.regionName(),
                    region.endpoint());
            });
        }
    });

    CompletableFuture<DescribeAvailabilityZonesResponse> zonesResponse =
ec2AsyncClient.describeAvailabilityZones();
    CompletableFuture<DescribeAvailabilityZonesResponse> zonesFuture =
zonesResponse.whenComplete((zonesResp, ex) -> {
        if (ex != null) {

```

```
        throw new RuntimeException("Failed to describe EC2 availability
zones.", ex);
    } else if (zonesResp == null || zonesResp.availabilityZones().isEmpty()) {
        throw new RuntimeException("No EC2 availability zones found.");
    } else {
        zonesResp.availabilityZones().forEach(zone -> {
            System.out.printf(
                "Found Availability Zone %s with status %s in region %s%n",
                zone.zoneName(),
                zone.state(),
                zone.regionName()
            );
        });
    }
});

return CompletableFuture.allOf(regionsFuture, zonesFuture);
}
}
```

See the [complete example](#) on GitHub.

Describe availability zones

To list each Availability Zone available to your account, call the `Ec2Client`'s `describeAvailabilityZones` method. It returns a [DescribeAvailabilityZonesResponse](#). Call its `availabilityZones` method to get a list of [AvailabilityZone](#) objects that represent each Availability Zone.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import java.util.concurrent.CompletableFuture;
```

Code

Create the `Ec2Client`.

```
Ec2AsyncClient ec2AsyncClient = Ec2AsyncClient.builder()
    .region(Region.US_EAST_1)
```

```
.build());
```

Then call `describeAvailabilityZones()` and retrieve results.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import java.util.concurrent.CompletableFuture;

/**

zones.", ex);
    } else if (zonesResp == null || zonesResp.availabilityZones().isEmpty()) {
        throw new RuntimeException("No EC2 availability zones found.");
    } else {
        zonesResp.availabilityZones().forEach(zone -> {
            System.out.printf(
                "Found Availability Zone %s with status %s in region %s%n",
                zone.zoneName(),
                zone.state(),
                zone.regionName()
            );
        });
    }
});
}
```

```
    });  
  
    return CompletableFuture.allOf(regionsFuture, zonesFuture);  
  }  
}
```

See the [complete example](#) on GitHub.

Describe accounts

To list EC2-related information about your account, call the `Ec2Client`'s `describeAccountAttributes` method. This method returns a [DescribeAccountAttributesResponse](#) object. Invoke this object's `accountAttributes` method to get a list of [AccountAttribute](#) objects. You can iterate through the list to retrieve an `AccountAttribute` object.

You can get your account's attribute values by invoking the `AccountAttribute` object's `attributeValues` method. This method returns a list of [AccountAttributeValue](#) objects. You can iterate through this second list to display the value of attributes (see the following code example).

Imports

```
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;  
import software.amazon.awssdk.services.ec2.model.DescribeAccountAttributesResponse;  
import java.util.concurrent.CompletableFuture;
```

Code

```
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.ec2.Ec2AsyncClient;  
import software.amazon.awssdk.services.ec2.model.DescribeAccountAttributesResponse;  
import java.util.concurrent.CompletableFuture;  
  
/**

     *
     * @param ec2AsyncClient the EC2 asynchronous client to use for the operation
     * @return a {@link CompletableFuture} containing the {@link
DescribeAccountAttributesResponse} with the account attributes
     */
    public static CompletableFuture<DescribeAccountAttributesResponse>
describeEC2AccountAsync(Ec2AsyncClient ec2AsyncClient) {
        CompletableFuture<DescribeAccountAttributesResponse> response =
ec2AsyncClient.describeAccountAttributes();
        return response.whenComplete((accountResults, ex) -> {
            if (ex != null) {
                // Handle the exception by throwing a RuntimeException.
                throw new RuntimeException("Failed to describe EC2 account
attributes.", ex);
            } else if (accountResults == null ||
accountResults.accountAttributes().isEmpty()) {
                // Throw an exception if the response is null or no account attributes
are found.
                throw new RuntimeException("No account attributes found.");
            } else {
                // Process the response if no exception occurred.
                accountResults.accountAttributes().forEach(attribute -> {
                    System.out.println("\nThe name of the attribute is " +
attribute.attributeName());
                    attribute.attributeValues().forEach(

```

```
        myValue -> System.out.println("The value of the attribute is "
+ myValue.attributeValue()));
    });
}
});
}
```

See the [complete example](#) on GitHub.

Work with security groups in Amazon EC2

Create a security group

To create a security group, call the `Ec2Client`'s `createSecurityGroup` method with a [CreateSecurityGroupRequest](#) that contains the key's name.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.IpPermission;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupResponse;
import software.amazon.awssdk.services.ec2.model.IpRange;
```

Code

```
        CreateSecurityGroupRequest createRequest =
CreateSecurityGroupRequest.builder()
    .groupName(groupName)
    .description(groupDesc)
```

```
        .vpcId(vpcId)
        .build();

    CreateSecurityGroupResponse resp= ec2.createSecurityGroup(createRequest);
```

See the [complete example](#) on GitHub.

Configure a security group

A security group can control both inbound (ingress) and outbound (egress) traffic to your Amazon EC2 instances.

To add ingress rules to your security group, use the `Ec2Client`'s `authorizeSecurityGroupIngress` method, providing the name of the security group and the access rules ([IpPermission](#)) you want to assign to it within an [AuthorizeSecurityGroupIngressRequest](#) object. The following example shows how to add IP permissions to a security group.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.IpPermission;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupResponse;
import software.amazon.awssdk.services.ec2.model.IpRange;
```

Code

First, create an `Ec2Client`

```
Region region = Region.US_WEST_2;
Ec2Client ec2 = Ec2Client.builder()
    .region(region)
    .build();
```

Then use the `Ec2Client`'s `authorizeSecurityGroupIngress` method,

```
IpRange ipRange = IpRange.builder()
```

```
        .cidrIp("0.0.0.0/0").build();

    IpPermission ipPerm = IpPermission.builder()
        .ipProtocol("tcp")
        .toPort(80)
        .fromPort(80)
        .ipRanges(ipRange)
        .build();

    IpPermission ipPerm2 = IpPermission.builder()
        .ipProtocol("tcp")
        .toPort(22)
        .fromPort(22)
        .ipRanges(ipRange)
        .build();

    AuthorizeSecurityGroupIngressRequest authRequest =
        AuthorizeSecurityGroupIngressRequest.builder()
            .groupName(groupName)
            .ipPermissions(ipPerm, ipPerm2)
            .build();

    AuthorizeSecurityGroupIngressResponse authResponse =
        ec2.authorizeSecurityGroupIngress(authRequest);

    System.out.printf(
        "Successfully added ingress policy to Security Group %s",
        groupName);

    return resp.groupId();

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return "";
}
```

To add an egress rule to the security group, provide similar data in an [AuthorizeSecurityGroupEgressRequest](#) to the `Ec2Client`'s `authorizeSecurityGroupEgress` method.

See the [complete example](#) on GitHub.

Describe security groups

To describe your security groups or get information about them, call the `Ec2Client`'s `describeSecurityGroups` method. It returns a [DescribeSecurityGroupsResponse](#) that you can use to access the list of security groups by calling its `securityGroups` method, which returns a list of [SecurityGroup](#) objects.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeSecurityGroupsRequest;
import software.amazon.awssdk.services.ec2.model.DescribeSecurityGroupsResponse;
import software.amazon.awssdk.services.ec2.model.SecurityGroup;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```
public static void describeEC2SecurityGroups(Ec2Client ec2, String groupId) {

    try {
        DescribeSecurityGroupsRequest request =
            DescribeSecurityGroupsRequest.builder()
                .groupIds(groupId).build();

        DescribeSecurityGroupsResponse response =
            ec2.describeSecurityGroups(request);

        for(SecurityGroup group : response.securityGroups()) {
            System.out.printf(
                "Found Security Group with id %s, " +
                "vpc id %s " +
                "and description %s",
                group.groupId(),
                group.vpcId(),
                group.description());
        }
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Delete a security group

To delete a security group, call the `Ec2Client`'s `deleteSecurityGroup` method, passing it a [DeleteSecurityGroupRequest](#) that contains the ID of the security group to delete.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DeleteSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```
public static void deleteEC2SecGroup(Ec2Client ec2,String groupId) {

    try {
        DeleteSecurityGroupRequest request = DeleteSecurityGroupRequest.builder()
            .groupId(groupId)
            .build();

        ec2.deleteSecurityGroup(request);
        System.out.printf(
            "Successfully deleted Security Group with id %s", groupId);

    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Work with Amazon EC2 instance metadata

A Java SDK client for the Amazon EC2 Instance Metadata Service (metadata client) allows your applications to access metadata on their local EC2 instance. The metadata client works with the local instance of [IMDSv2](#) (Instance Metadata Service v2) and uses session-oriented requests.

Two client classes are available in the SDK. The synchronous [Ec2MetadataClient](#) is for blocking operations, and the [Ec2MetadataAsyncClient](#) is for asynchronous, non-blocking use cases.

Get started

To use the metadata client, add the `imds` Maven artifact to your project. You also need classes for an [SdkHttpClient](#) (or an [SdkAsyncHttpClient](#) for the asynchronous variant) on the classpath.

The following Maven XML shows dependency snippets for using the synchronous [URLConnectionHttpClient](#) along with the dependency for metadata clients.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>VERSION</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>imds</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
```

```

    <artifactId>url-connection-client</artifactId>
  </dependency>
  <!-- other dependencies -->
</dependencies>

```

Search the [Maven central repository](#) for the latest version of the bom artifact.

To use an asynchronous HTTP client, replace the dependency snippet for the `url-connection-client` artifact. For example, the following snippet brings in the [NettyNioAsyncHttpClient](#) implementation.

```

<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>netty-nio-client</artifactId>
</dependency>

```

Use the metadata client

Instantiate a metadata client

You can instantiate an instance of a synchronous `Ec2MetadataClient` when only one implementation of the `SdkHttpClient` interface is present on the classpath. To do so, call the static `Ec2MetadataClient#create()` method as shown in the following snippet.

```

Ec2MetadataClient client = Ec2MetadataClient.create(); //
'Ec2MetadataAsyncClient#create' is the asynchronous version.

```

If your application has multiple implementations of the `SdkHttpClient` or `SdkHttpAsyncClient` interface, you must specify an implementation for the metadata client to use as shown in the [the section called "Configurable HTTP client"](#) section.

Note

For most service clients, such as Amazon S3, the SDK for Java automatically adds implementations of the `SdkHttpClient` or `SdkHttpAsyncClient` interface. If your metadata client uses the same implementation, then `Ec2MetadataClient#create()` will work. If you require a different implementation, you must specify it when you create the metadata client.

Send requests

To retrieve instance metadata, instantiate the `Ec2MetadataClient` class and call the `get` method with a path parameter that specifies the [instance metadata category](#).

The following example prints the value associated with the `ami-id` key to the console.

```
Ec2MetadataClient client = Ec2MetadataClient.create();
Ec2MetadataResponse response = client.get("/latest/meta-data/ami-id");
System.out.println(response.asString());
client.close(); // Closes the internal resources used by the Ec2MetadataClient class.
```

If the path isn't valid, the `get` method throws an exception.

Reuse the same client instance for multiple requests, but call `close` on the client when it is no longer needed to release resources. After the `close` method is called, the client instance can't be used anymore.

Parse responses

EC2 instance metadata can be output in different formats. Plain text and JSON are the most commonly used formats. The metadata clients offer ways to work with those formats.

As the following example shows, use the `asString` method to get the data as a Java string. You can also use the `asList` method to separate a plain text response that returns multiple lines.

```
Ec2MetadataClient client = Ec2MetadataClient.create();
Ec2MetadataResponse response = client.get("/latest/meta-data/");
String fullResponse = response.asString();
List<String> splits = response.asList();
```

If the response is in JSON, use the `Ec2MetadataResponse#asDocument` method to parse the JSON response into a [Document](#) instance as shown in the following code snippet.

```
Document fullResponse = response.asDocument();
```

An exception will be thrown if the format of the metadata is not in JSON. If the response is successfully parsed, you can use the [document API](#) to inspect the response in more detail. Consult the instance [metadata category chart](#) to learn which metadata categories deliver JSON-formatted responses.

Configure a metadata client

Retries

You can configure a metadata client with a retry mechanism. If you do, then the client can automatically retry requests that fail for unexpected reasons. By default, the client retries three times on a failed request with an exponential backoff time between attempts.

If your use case requires a different retry mechanism, you can customize the client using the `retryPolicy` method on its builder. For example, the following example shows a synchronous client configured with a fixed delay of two seconds between attempts and five retry attempts.

```
BackoffStrategy fixedBackoffStrategy =
    FixedDelayBackoffStrategy.create(Duration.ofSeconds(2));
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .retryPolicy(retryPolicyBuilder ->
            retryPolicyBuilder.numRetries(5)

            .backoffStrategy(fixedBackoffStrategy))
        .build();
```

There are several [BackoffStrategies](#) that you can use with a metadata client.

You can also disable the retry mechanism entirely, as the following snippet shows.

```
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .retryPolicy(Ec2MetadataRetryPolicy.none())
        .build();
```

Using `Ec2MetadataRetryPolicy#none()` disables the default retry policy so that the metadata client attempts no retries.

IP version

By default, a metadata client uses the IPV4 endpoint at `http://169.254.169.254`. To change the client to use the IPV6 version, use either the `endpointMode` or the `endpoint` method of the builder. An exception results if both methods are called on the builder.

The following examples show both IPV6 options.

```
Ec2MetadataClient client =  
    Ec2MetadataClient.builder()  
        .endpointMode(EndpointMode.IPV6)  
        .build();
```

```
Ec2MetadataClient client =  
    Ec2MetadataClient.builder()  
        .endpoint(URI.create("http://[fd00:ec2::254]"))  
        .build();
```

Key features

Asynchronous client

To use the non-blocking version of the client, instantiate an instance of the `Ec2MetadataAsyncClient` class. The code in the following example creates an asynchronous client with default settings and uses the `get` method to retrieve the value for the `ami-id` key.

```
Ec2MetadataAsyncClient asyncClient = Ec2MetadataAsyncClient.create();  
CompletableFuture<Ec2MetadataResponse> response = asyncClient.get("/latest/meta-data/  
ami-id");
```

The `java.util.concurrent.CompletableFuture` returned by the `get` method completes when the response returns. The following example prints the `ami-id` metadata to the console.

```
response.thenAccept(metadata -> System.out.println(metadata.asString()));
```

Configurable HTTP client

The builder for each metadata client has a `httpClient` method that you can use to supply a customized HTTP client.

The following example shows code for a custom `URLConnectionHttpClient` instance.

```
SdkHttpClient httpClient =  
    UrlConnectionHttpClient.builder()  
        .socketTimeout(Duration.ofMinutes(5))  
        .proxyConfiguration(proxy ->  
            proxy.endpoint(URI.create("http://proxy.example.net:8888"))))
```

```
                .build();
Ec2MetadataClient metaDataClient =
    Ec2MetadataClient.builder()
        .httpClient(httpClient)
        .build();
// Use the metaDataClient instance.
metaDataClient.close(); // Close the instance when no longer needed.
```

The following example shows code for a custom `NettyNioAsyncHttpClient` instance with an asynchronous metadata client.

```
SdkAsyncHttpClient httpAsyncClient =
    NettyNioAsyncHttpClient.builder()
        .connectionTimeout(Duration.ofMinutes(5))
        .maxConcurrency(100)
        .build();
Ec2MetadataAsyncClient asyncMetaDataClient =
    Ec2MetadataAsyncClient.builder()
        .httpClient(httpAsyncClient)
        .build();
// Use the asyncMetaDataClient instance.
asyncMetaDataClient.close(); // Close the instance when no longer needed.
```

The [the section called “HTTP clients”](#) topic in this guide provides details on how to configure the HTTP clients that are available in the SDK for Java.

Token caching

Because the metadata clients use IMDSv2, all requests are associated with a session. A session is defined by a token that has an expiration, which the metadata client manages for you. Every metadata request automatically reuses the token until it expires.

By default, a token lasts for six hours (21,600 seconds). We recommend that you keep the default time-to-live value, unless your specific use case requires advanced configuration.

If needed, configure the duration by using the `tokenTtl` builder method. For example, the code in the following snippet creates a client with a session duration of five minutes.

```
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .tokenTtl(Duration.ofMinutes(5))
```

```
.build();
```

If you omit calling the `tokenTtl` method on the builder, the default duration of 21,600 is used instead.

Work with IAM

This section provides examples of programming AWS Identity and Access Management (IAM) by using the AWS SDK for Java 2.x.

AWS Identity and Access Management (IAM) enables you to securely control access to AWS services and resources for your users. Using IAM, you can create and manage AWS users and groups, and use permissions to allow and deny their access to AWS resources. For a complete guide to IAM, visit the [IAM User Guide](#).

The following examples include only the code needed to demonstrate each technique. The [complete example code is available on GitHub](#). From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- [Manage IAM access keys](#)
- [Manage IAM Users](#)
- [Create IAM policies with the AWS SDK for Java 2.x](#)
- [Work with IAM policies](#)
- [Work with IAM server certificates](#)

Manage IAM access keys

Create an access key

To create an IAM access key, call the `IamClient`'s `createAccessKey` method with a [CreateAccessKeyRequest](#) object.

Note

You must set the region to **AWS_GLOBAL** for `IamClient` calls to work because IAM is a global service.

Imports

```
import software.amazon.awssdk.services.iam.model.CreateAccessKeyRequest;
import software.amazon.awssdk.services.iam.model.CreateAccessKeyResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static String createIAMAccessKey(IamClient iam,String user) {

    try {
        CreateAccessKeyRequest request = CreateAccessKeyRequest.builder()
            .userName(user).build();

        CreateAccessKeyResponse response = iam.createAccessKey(request);
        String keyId = response.accessKey().accessKeyId();
        return keyId;

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

See the [complete example](#) on GitHub.

List access keys

To list the access keys for a given user, create a [ListAccessKeysRequest](#) object that contains the user name to list keys for, and pass it to the `IamClient`'s `listAccessKeys` method.

Note

If you do not supply a user name to `listAccessKeys`, it will attempt to list access keys associated with the AWS account that signed the request.

Imports

```
import software.amazon.awssdk.services.iam.model.AccessKeyMetadata;  
import software.amazon.awssdk.services.iam.model.IamException;  
import software.amazon.awssdk.services.iam.model.ListAccessKeysRequest;  
import software.amazon.awssdk.services.iam.model.ListAccessKeysResponse;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```
public static void listKeys( IamClient iam,String userName ){  
  
    try {  
        boolean done = false;  
        String newMarker = null;  
  
        while (!done) {  
            ListAccessKeysResponse response;  
  
            if(newMarker == null) {  
                ListAccessKeysRequest request = ListAccessKeysRequest.builder()  
                    .userName(userName).build();  
                response = iam.listAccessKeys(request);  
            } else {  
                ListAccessKeysRequest request = ListAccessKeysRequest.builder()  
                    .userName(userName)  
                    .marker(newMarker).build();  
                response = iam.listAccessKeys(request);  
            }  
  
            for (AccessKeyMetadata metadata :  
                response.accessKeyMetadata()) {  
                System.out.format("Retrieved access key %s",  
                    metadata.accessKeyId());  
            }  
  
            if (!response.isTruncated()) {  
                done = true;  
            } else {  
                newMarker = response.marker();  
            }  
        }  
  
    } catch (IamException e) {
```

```
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

The results of `listAccessKeys` are paged (with a default maximum of 100 records per call). You can call `isTruncated` on the returned [ListAccessKeysResponse](#) object to see if the query returned fewer results than are available. If so, then call `marker` on the `ListAccessKeysResponse` and use it when creating a new request. Use that new request in the next invocation of `listAccessKeys`.

See the [complete example](#) on GitHub.

Retrieve an access key's last used time

To get the time an access key was last used, call the `IamClient`'s `getAccessKeyLastUsed` method with the access key's ID (which can be passed in using a [GetAccessKeyLastUsedRequest](#) object).

You can then use the returned [GetAccessKeyLastUsedResponse](#) object to retrieve the key's last used time.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.GetAccessKeyLastUsedRequest;
import software.amazon.awssdk.services.iam.model.GetAccessKeyLastUsedResponse;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void getAccessKeyLastUsed(IamClient iam, String accessId ){

    try {
        GetAccessKeyLastUsedRequest request = GetAccessKeyLastUsedRequest.builder()
            .accessKeyId(accessId).build();

        GetAccessKeyLastUsedResponse response = iam.getAccessKeyLastUsed(request);
    }
}
```

```
        System.out.println("Access key was last used at: " +
            response.accessKeyLastUsed().lastUsedDate());

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    System.out.println("Done");
}
```

See the [complete example](#) on GitHub.

Activate or deactivate access keys

You can activate or deactivate an access key by creating an [UpdateAccessKeyRequest](#) object, providing the access key ID, optionally the user name, and the desired [status](#), then passing the request object to the `IamClient`'s `updateAccessKey` method.

Imports

```
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.StatusType;
import software.amazon.awssdk.services.iam.model.UpdateAccessKeyRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```
public static void updateKey(IamClient iam, String username, String accessId,
    String status ) {

    try {
        if (status.toLowerCase().equalsIgnoreCase("active")) {
            statusType = StatusType.ACTIVE;
        } else if (status.toLowerCase().equalsIgnoreCase("inactive")) {
            statusType = StatusType.INACTIVE;
        } else {
            statusType = StatusType.UNKNOWN_TO_SDK_VERSION;
        }
        UpdateAccessKeyRequest request = UpdateAccessKeyRequest.builder()
            .accessKeyId(accessId)
            .userName(username)
```

```
        .status(statusType)
        .build();

iam.updateAccessKey(request);

System.out.printf(
    "Successfully updated the status of access key %s to" +
    "status %s for user %s", accessId, status, username);
} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Delete an access key

To permanently delete an access key, call the `IamClient`'s `deleteKey` method, providing it with a [DeleteAccessKeyRequest](#) containing the access key's ID and username.

Note

Once deleted, a key can no longer be retrieved or used. To temporarily deactivate a key so that it can be activated again later, use [updateAccessKey](#) method instead.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.DeleteAccessKeyRequest;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void deleteKey(IamClient iam ,String username, String accessKey ) {

    try {
        DeleteAccessKeyRequest request = DeleteAccessKeyRequest.builder()
```

```
        .accessKeyId(accessKey)
        .userName(username)
        .build();

    iam.deleteAccessKey(request);
    System.out.println("Successfully deleted access key " + accessKey +
        " from user " + username);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

- [DeleteAccessKey](#) in the IAM API Reference

Manage IAM Users

Create a User

Create a new IAM user by providing the user name to the `IamClient`'s `createUser` method using a [CreateUserRequest](#) object containing the user name.

Imports

```
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.services.iam.model.CreateUserRequest;
import software.amazon.awssdk.services.iam.model.CreateUserResponse;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

```
import software.amazon.awssdk.services.iam.waiters.IamWaiter;
import software.amazon.awssdk.services.iam.model.GetUserRequest;
import software.amazon.awssdk.services.iam.model.GetUserResponse;
```

Code

```
public static String createIAMUser(IamClient iam, String username ) {

    try {
        // Create an IamWaiter object
        IamWaiter iamWaiter = iam.waiter();

        CreateUserRequest request = CreateUserRequest.builder()
            .userName(username)
            .build();

        CreateUserResponse response = iam.createUser(request);

        // Wait until the user is created
        GetUserRequest userRequest = GetUserRequest.builder()
            .userName(response.user().userName())
            .build();

        WaiterResponse<GetUserResponse> waitUntilUserExists =
iamWaiter.waitUntilUserExists(userRequest);
        waitUntilUserExists.matched().response().ifPresent(System.out::println);
        return response.user().userName();

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

See the [complete example](#) on GitHub.

List Users

To list the IAM users for your account, create a new [ListUsersRequest](#) and pass it to the `IamClient`'s `listUsers` method. You can retrieve the list of users by calling `users` on the returned [ListUsersResponse](#) object.

The list of users returned by `listUsers` is paged. You can check to see there are more results to retrieve by calling the response object's `isTruncated` method. If it returns `true`, then call the response object's `marker()` method. Use the marker value to create a new request object. Then call the `listUsers` method again with the new request.

Imports

```
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListUsersRequest;
import software.amazon.awssdk.services.iam.model.ListUsersResponse;
import software.amazon.awssdk.services.iam.model.User;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```
public static void listAllUsers(IamClient iam ) {

    try {

        boolean done = false;
        String newMarker = null;

        while(!done) {
            ListUsersResponse response;

            if (newMarker == null) {
                ListUsersRequest request = ListUsersRequest.builder().build();
                response = iam.listUsers(request);
            } else {
                ListUsersRequest request = ListUsersRequest.builder()
                    .marker(newMarker).build();
                response = iam.listUsers(request);
            }

            for(User user : response.users()) {
                System.out.format("\n Retrieved user %s", user.userName());
            }

            if(!response.isTruncated()) {
                done = true;
            } else {
                newMarker = response.marker();
            }
        }
    }
}
```

```
        }
    }
} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Update a User

To update a user, call the `IamClient` object's `updateUser` method, which takes a [UpdateUserRequest](#) object that you can use to change the user's *name* or *path*.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.UpdateUserRequest;
```

Code

```
public static void updateIAMUser(IamClient iam, String curName, String newName ) {

    try {
        UpdateUserRequest request = UpdateUserRequest.builder()
            .userName(curName)
            .newUserName(newName)
            .build();

        iam.updateUser(request);
        System.out.printf("Successfully updated user to username %s",
            newName);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Delete a User

To delete a user, call the `IamClient`'s `deleteUser` request with a [UpdateUserRequest](#) object set with the user name to delete.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.DeleteUserRequest;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void deleteIAMUser(IamClient iam, String userName) {

    try {
        DeleteUserRequest request = DeleteUserRequest.builder()
            .userName(userName)
            .build();

        iam.deleteUser(request);
        System.out.println("Successfully deleted IAM user " + userName);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Create IAM policies with the AWS SDK for Java 2.x

The [IAM Policy Builder API](#) is a library that you can use to build [IAM policies](#) in Java and upload them to AWS Identity and Access Management (IAM).

Instead of building an IAM policy by manually assembling a JSON string or by reading a file, the API provides a client-side, object-oriented approach to generate the JSON string. When you read an existing IAM policy in JSON format, the API converts it to an [IamPolicy](#) instance for handling.

The IAM Policy Builder API became available with version 2.20.105 of the SDK, so use that version or a later one in your Maven build file. The latest version number of the SDK is [listed on Maven central](#).

The following snippet shows an example dependency block for a Maven pom.xml file. This allows you to use the IAM Policy Builder API in your project.

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>iam-policy-builder</artifactId>
  <version>2.27.21</version>
</dependency>
```

Create an IamPolicy

This section shows several examples of how to build policies by using the IAM Policy Builder API.

In each of the following examples, start with the [IamPolicy.Builder](#) and add one or more statements by using the `addStatement` method. Following this pattern, the [IamStatement.Builder](#) has methods to add the effect, actions, resources, and conditions to the statement.

Example: Create a time-based policy

The following example creates an identity-based policy that permits the Amazon DynamoDB `GetItem` action between two points in time.

```
public String timeBasedPolicyExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:GetItem")
            .addResource(IamResource.ALL)
```

```
        .addCondition(b1 -> b1
            .operator(IamConditionOperator.DATE_GREATER_THAN)
            .key("aws:CurrentTime")
            .value("2020-04-01T00:00:00Z"))
        .addCondition(b1 -> b1
            .operator(IamConditionOperator.DATE_LESS_THAN)
            .key("aws:CurrentTime")
            .value("2020-06-30T23:59:59Z"))
    .build();

    // Use an IamPolicyWriter to write out the JSON string to a more readable
    format.
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true)
        .build());
}
```

JSON output

The last statement in the previous example returns the following JSON string.

Read more about this [example](#) in the *AWS Identity and Access Management User Guide*.

```
{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Action" : "dynamodb:GetItem",
    "Resource" : "*",
    "Condition" : {
      "DateGreaterThan" : {
        "aws:CurrentTime" : "2020-04-01T00:00:00Z"
      },
      "DateLessThan" : {
        "aws:CurrentTime" : "2020-06-30T23:59:59Z"
      }
    }
  }
}
```

Example: Specify multiple conditions

The following example shows how you can create an identity-based policy that allows access to specific DynamoDB attributes. The policy contains two conditions.

```

public String multipleConditionsExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:GetItem")
            .addAction("dynamodb:BatchGetItem")
            .addAction("dynamodb:Query")
            .addAction("dynamodb:PutItem")
            .addAction("dynamodb:UpdateItem")
            .addAction("dynamodb>DeleteItem")
            .addAction("dynamodb:BatchWriteItem")
            .addResource("arn:aws:dynamodb:*:*:table/table-name")

        .addConditions(IamConditionOperator.STRING_EQUALS.addPrefix("ForAllValues:"),
            "dynamodb:Attributes",
            List.of("column-name1", "column-name2", "column-
name3"))

            .addCondition(b1 ->
b1.operator(IamConditionOperator.STRING_EQUALS.addSuffix("IfExists"))
                .key("dynamodb:Select")
                .value("SPECIFIC_ATTRIBUTES")))

        .build();

    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}

```

JSON output

The last statement in the previous example returns the following JSON string.

Read more about this [example](#) in the *AWS Identity and Access Management User Guide*.

```

{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Action" : [ "dynamodb:GetItem", "dynamodb:BatchGetItem", "dynamodb:Query",
"dynamodb:PutItem", "dynamodb:UpdateItem", "dynamodb>DeleteItem",
"dynamodb:BatchWriteItem" ],
    "Resource" : "arn:aws:dynamodb:*:*:table/table-name",
    "Condition" : {
      "ForAllValues:StringEquals" : {

```

```

    "dynamodb:Attributes" : [ "column-name1", "column-name2", "column-name3" ]
  },
  "StringEqualsIfExists" : {
    "dynamodb:Select" : "SPECIFIC_ATTRIBUTES"
  }
}

```

Example: Specify principals

The following example shows how to create a resource-based policy that denies access to a bucket for all principals except for those specified in the condition.

```

public String specifyPrincipalsExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.DENY)
            .addAction("s3:*")
            .addPrincipal(IamPrincipal.ALL)
            .addResource("arn:aws:s3:::BUCKETNAME/*")
            .addResource("arn:aws:s3:::BUCKETNAME")
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.ARN_NOT_EQUALS)
                .key("aws:PrincipalArn")
                .value("arn:aws:iam::444455556666:user/user-name")))
        .build();
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}

```

JSON output

The last statement in the previous example returns the following JSON string.

Read more about this [example](#) in the *AWS Identity and Access Management User Guide*.

```

{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Deny",
    "Principal" : "*",
    "Action" : "s3:*",

```

```

"Resource" : [ "arn:aws:s3:::BUCKETNAME/*", "arn:aws:s3:::BUCKETNAME" ],
"Condition" : {
  "ArnNotEquals" : {
    "aws:PrincipalArn" : "arn:aws:iam::444455556666:user/user-name"
  }
}
}
}
}

```

Example: Allow cross-account access

The following example shows how to allow another AWS account to upload objects to your bucket while retaining full owner control of the uploaded objects.

```

public String allowCrossAccountAccessExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addPrincipal(IamPrincipalType.AWS, "111122223333")
            .addAction("s3:PutObject")
            .addResource("arn:aws:s3:::amzn-s3-demo-bucket/*")
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.STRING_EQUALS)
                .key("s3:x-amz-acl")
                .value("bucket-owner-full-control")))
        .build();
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}

```

JSON output

The last statement in the previous example returns the following JSON string.

Read more about this [example](#) in the *Amazon Simple Storage Service User Guide*.

```

{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "111122223333"
    }
  },
}

```

```

    "Action" : "s3:PutObject",
    "Resource" : "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition" : {
      "StringEquals" : {
        "s3:x-amz-acl" : "bucket-owner-full-control"
      }
    }
  }
}

```

Use an `IamPolicy` with IAM

After you have created a `IamPolicy` instance, you use an [IamClient](#) to work with the IAM service.

The following example builds a policy that allows an [IAM identity](#) to write items to a DynamoDB table in the account that is specified with the `accountID` parameter. The policy is then uploaded to IAM as a JSON string.

```

public String createAndUploadPolicyExample(IamClient iam, String accountID, String
policyName) {
    // Build the policy.
    IamPolicy policy =
        IamPolicy.builder() // 'version' defaults to "2012-10-17".
            .addStatement(IamStatement.builder()
                .effect(IamEffect.ALLOW)
                .addAction("dynamodb:PutItem")
                .addResource("arn:aws:dynamodb:us-east-1:" + accountID
+ ":table/exampleTableName")
            .build())
        .build();
    // Upload the policy.
    iam.createPolicy(r ->
r.policyName(policyName).policyDocument(policy.toJson()));
    return policy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
}

```

The next example builds on the previous example. The code downloads the policy and uses it as the basis for a new policy by copying and altering the statement. The new policy is then uploaded.

```

public String createNewBasedOnExistingPolicyExample(IamClient iam, String
accountID, String policyName, String newPolicyName) {

```

```

        String policyArn = "arn:aws:iam::" + accountID + ":policy/" + policyName;
        GetPolicyResponse getPolicyResponse = iam.getPolicy(r ->
r.policyArn(policyArn));

        String policyVersion = getPolicyResponse.policy().defaultVersionId();
        GetPolicyVersionResponse getPolicyVersionResponse =
            iam.getPolicyVersion(r ->
r.policyArn(policyArn).versionId(policyVersion));

        // Create an IamPolicy instance from the JSON string returned from IAM.
        String decodedPolicy =
URLDecoder.decode(getPolicyVersionResponse.policyVersion().document(),
StandardCharsets.UTF_8);
        IamPolicy policy = IamPolicy.fromJson(decodedPolicy);

        /*
            All IamPolicy components are immutable, so use the copy method that
            creates a new instance that
            can be altered in the same method call.

            Add the ability to get an item from DynamoDB as an additional action.
        */
        IamStatement newStatement = policy.statements().get(0).copy(s ->
s.addAction("dynamodb:GetItem"));

        // Create a new statement that replaces the original statement.
        IamPolicy newPolicy = policy.copy(p ->
p.statements(Arrays.asList(newStatement)));

        // Upload the new policy. IAM now has both policies.
        iam.createPolicy(r -> r.policyName(newPolicyName)
            .policyDocument(newPolicy.toJson()));

        return newPolicy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
    }

```

IamClient

The previous examples use an `IamClient` argument that is created as shown in the following snippet.

```
IamClient iam = IamClient.builder().region(Region.AWS_GLOBAL).build();
```

Policies in JSON

The examples return the following JSON strings.

First example

```
{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Action" : "dynamodb:PutItem",
    "Resource" : "arn:aws:dynamodb:us-east-1:111122223333:table/exampleTableName"
  }
}
```

Second example

```
{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Action" : [ "dynamodb:PutItem", "dynamodb:GetItem" ],
    "Resource" : "arn:aws:dynamodb:us-east-1:111122223333:table/exampleTableName"
  }
}
```

Work with IAM policies

Create a policy

To create a new policy, provide the policy's name and a JSON-formatted policy document in a [CreatePolicyRequest](#) to the `IamClient`'s `createPolicy` method.

Imports

```
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.services.iam.model.CreatePolicyRequest;
import software.amazon.awssdk.services.iam.model.CreatePolicyResponse;
import software.amazon.awssdk.services.iam.model.GetPolicyRequest;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.waiters.IamWaiter;
```

Code

```
public static String createIAMPolicy(IamClient iam, String policyName ) {

    try {
        // Create an IamWaiter object
        IamWaiter iamWaiter = iam.waiter();

        CreatePolicyRequest request = CreatePolicyRequest.builder()
            .policyName(policyName)
            .policyDocument(PolicyDocument).build();

        CreatePolicyResponse response = iam.createPolicy(request);

        // Wait until the policy is created
        GetPolicyRequest polRequest = GetPolicyRequest.builder()
            .policyArn(response.policy().arn())
            .build();

        WaiterResponse<GetPolicyResponse> waitUntilPolicyExists =
iamWaiter.waitUntilPolicyExists(polRequest);
        waitUntilPolicyExists.matched().response().ifPresent(System.out::println);
        return response.policy().arn();

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "" ;
}
```

See the [complete example](#) on GitHub.

Get a policy

To retrieve an existing policy, call the `IamClient`'s `getPolicy` method, providing the policy's ARN within a [GetPolicyRequest](#) object.

Imports

```
import software.amazon.awssdk.services.iam.model.GetPolicyRequest;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.regions.Region;
```

```
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void getIAMPolicy(IamClient iam, String policyArn) {

    try {
        GetPolicyRequest request = GetPolicyRequest.builder()
            .policyArn(policyArn).build();

        GetPolicyResponse response = iam.getPolicy(request);
        System.out.format("Successfully retrieved policy %s",
            response.policy().policyName());

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Attach a role policy

You can attach a policy to an IAM [role](#) by calling the `IamClient`'s `attachRolePolicy` method, providing it with the role name and policy ARN in an [AttachRolePolicyRequest](#).

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.AttachRolePolicyRequest;
import software.amazon.awssdk.services.iam.model.AttachedPolicy;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesRequest;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesResponse;
import java.util.List;
```

Code

```
public static void attachIAMRolePolicy(IamClient iam, String roleName, String
policyArn ) {
```

```
try {

    ListAttachedRolePoliciesRequest request =
ListAttachedRolePoliciesRequest.builder()
    .roleName(roleName)
    .build();

    ListAttachedRolePoliciesResponse response =
iam.listAttachedRolePolicies(request);
    List<AttachedPolicy> attachedPolicies = response.attachedPolicies();

    // Ensure that the policy is not attached to this role
    String polArn = "";
    for (AttachedPolicy policy: attachedPolicies) {
        polArn = policy.policyArn();
        if (polArn.compareTo(policyArn)==0) {
            System.out.println(roleName +
                " policy is already attached to this role.");
            return;
        }
    }

    AttachRolePolicyRequest attachRequest =
        AttachRolePolicyRequest.builder()
            .roleName(roleName)
            .policyArn(policyArn)
            .build();

    iam.attachRolePolicy(attachRequest);

    System.out.println("Successfully attached policy " + policyArn +
        " to role " + roleName);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

System.out.println("Done");
}
```

See the [complete example](#) on GitHub.

List attached role policies

List attached policies on a role by calling the `IamClient`'s `listAttachedRolePolicies` method. It takes a [ListAttachedRolePoliciesRequest](#) object that contains the role name to list the policies for.

Call `getAttachedPolicies` on the returned [ListAttachedRolePoliciesResponse](#) object to get the list of attached policies. Results may be truncated; if the `ListAttachedRolePoliciesResponse` object's `isTruncated` method returns `true`, call the `ListAttachedRolePoliciesResponse` object's `marker` method. Use the marker returned to create a new request and use it to call `listAttachedRolePolicies` again to get the next batch of results.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.AttachRolePolicyRequest;
import software.amazon.awssdk.services.iam.model.AttachedPolicy;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesRequest;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesResponse;
import java.util.List;
```

Code

```
public static void attachIAMRolePolicy(IamClient iam, String roleName, String
policyArn ) {

    try {

        ListAttachedRolePoliciesRequest request =
ListAttachedRolePoliciesRequest.builder()
        .roleName(roleName)
        .build();

        ListAttachedRolePoliciesResponse response =
iam.listAttachedRolePolicies(request);
        List<AttachedPolicy> attachedPolicies = response.attachedPolicies();

        // Ensure that the policy is not attached to this role
        String polArn = "";
        for (AttachedPolicy policy: attachedPolicies) {
```

```
        polArn = policy.policyArn();
        if (polArn.compareTo(policyArn)==0) {
            System.out.println(roleName +
                " policy is already attached to this role.");
            return;
        }
    }

    AttachRolePolicyRequest attachRequest =
        AttachRolePolicyRequest.builder()
            .roleName(roleName)
            .policyArn(policyArn)
            .build();

    iam.attachRolePolicy(attachRequest);

    System.out.println("Successfully attached policy " + policyArn +
        " to role " + roleName);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

System.out.println("Done");
}
```

See the [complete example](#) on GitHub.

Detach a role policy

To detach a policy from a role, call the `IamClient`'s `detachRolePolicy` method, providing it with the role name and policy ARN in a [DetachRolePolicyRequest](#).

Imports

```
import software.amazon.awssdk.services.iam.model.DetachRolePolicyRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void detachPolicy(IamClient iam, String roleName, String policyArn )
{
    try {
        DetachRolePolicyRequest request = DetachRolePolicyRequest.builder()
            .roleName(roleName)
            .policyArn(policyArn)
            .build();

        iam.detachRolePolicy(request);
        System.out.println("Successfully detached policy " + policyArn +
            " from role " + roleName);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Work with IAM server certificates

To enable HTTPS connections to your website or application on AWS, you need an SSL/TLS *server certificate*. You can use a server certificate provided by AWS Certificate Manager or one that you obtained from an external provider.

We recommend that you use ACM to provision, manage, and deploy your server certificates. With ACM you can request a certificate, deploy it to your AWS resources, and let ACM handle certificate

renewals for you. Certificates provided by ACM are free. For more information about ACM, see the [AWS Certificate Manager User Guide](#).

Get a server certificate

You can retrieve a server certificate by calling the `IamClient`'s `getServerCertificate` method, passing it a [GetServerCertificateRequest](#) with the certificate's name.

Imports

```
import software.amazon.awssdk.services.iam.model.GetServerCertificateRequest;
import software.amazon.awssdk.services.iam.model.GetServerCertificateResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void getCertificate(IamClient iam, String certName ) {

    try {
        GetServerCertificateRequest request = GetServerCertificateRequest.builder()
            .serverCertificateName(certName)
            .build();

        GetServerCertificateResponse response = iam.getServerCertificate(request);
        System.out.format("Successfully retrieved certificate with body %s",
            response.getServerCertificate().certificateBody());

    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

List server certificates

To list your server certificates, call the `IamClient`'s `listServerCertificates` method with a [ListServerCertificatesRequest](#). It returns a [ListServerCertificatesResponse](#).

Call the returned `ListServerCertificateResponse` object's `serverCertificateMetadataList` method to get a list of [ServerCertificateMetadata](#) objects that you can use to get information about each certificate.

Results may be truncated; if the `ListServerCertificateResponse` object's `isTruncated` method returns `true`, call the `ListServerCertificatesResponse` object's `marker` method and use the marker to create a new request. Use the new request to call `listServerCertificates` again to get the next batch of results.

Imports

```
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListServerCertificatesRequest;
import software.amazon.awssdk.services.iam.model.ListServerCertificatesResponse;
import software.amazon.awssdk.services.iam.model.ServerCertificateMetadata;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```
public static void listCertificates(IamClient iam) {

    try {
        boolean done = false;
        String newMarker = null;

        while(!done) {
            ListServerCertificatesResponse response;

            if (newMarker == null) {
                ListServerCertificatesRequest request =
                    ListServerCertificatesRequest.builder().build();
                response = iam.listServerCertificates(request);
            } else {
                ListServerCertificatesRequest request =
                    ListServerCertificatesRequest.builder()
                        .marker(newMarker).build();
                response = iam.listServerCertificates(request);
            }

            for(ServerCertificateMetadata metadata :
                response.serverCertificateMetadataList()) {
```

```
        System.out.printf("Retrieved server certificate %s",
                           metadata.serverCertificateName());
    }

    if(!response.isTruncated()) {
        done = true;
    } else {
        newMarker = response.marker();
    }
}

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Update a server certificate

You can update a server certificate's name or path by calling the `IamClient`'s `updateServerCertificate` method. It takes a [UpdateServerCertificateRequest](#) object set with the server certificate's current name and either a new name or new path to use.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.UpdateServerCertificateRequest;
import software.amazon.awssdk.services.iam.model.UpdateServerCertificateResponse;
```

Code

```
public static void updateCertificate(IamClient iam, String curName, String newName)
{
    try {
        UpdateServerCertificateRequest request =
            UpdateServerCertificateRequest.builder()
                .serverCertificateName(curName)
```

```
        .newServerCertificateName(newName)
        .build();

    UpdateServerCertificateResponse response =
        iam.updateServerCertificate(request);

    System.out.printf("Successfully updated server certificate to name %s",
        newName);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}
```

See the [complete example](#) on GitHub.

Delete a server certificate

To delete a server certificate, call the `IamClient`'s `deleteServerCertificate` method with a [DeleteServerCertificateRequest](#) containing the certificate's name.

Imports

```
import software.amazon.awssdk.services.iam.model.DeleteServerCertificateRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```
public static void deleteCert(IamClient iam, String certName ) {

    try {
        DeleteServerCertificateRequest request =
            DeleteServerCertificateRequest.builder()
                .serverCertificateName(certName)
                .build();

        iam.deleteServerCertificate(request);
        System.out.println("Successfully deleted server certificate " +
            certName);
    }
}
```

```
    } catch (IamException e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

See the [complete example](#) on GitHub.

Work with Kinesis

This section provides examples of programming [Amazon Kinesis](#) using the AWS SDK for Java 2.x.

For more information about Kinesis, see the [Amazon Kinesis Developer Guide](#).

The following examples include only the code needed to demonstrate each technique. The [complete example code is available on GitHub](#). From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- [Subscribe to Amazon Kinesis Data Streams](#)

Subscribe to Amazon Kinesis Data Streams

The following examples show you how to retrieve and process data from Amazon Kinesis Data Streams using the `subscribeToShard` method. Kinesis Data Streams now employs the enhanced fanout feature and a low-latency HTTP/2 data retrieval API, making it easier for developers to run multiple low-latency, high-performance applications on the same Kinesis Data Stream.

Set up

First, create an asynchronous Kinesis client and a [SubscribeToShardRequest](#) object. These objects are used in each of the following examples to subscribe to Kinesis events.

Imports

```
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.atomic.AtomicInteger;
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisAsyncClient;
import software.amazon.awssdk.services.kinesis.model.ShardIteratorType;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEvent;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEventStream;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardRequest;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardResponse;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardResponseHandler;
```

Code

```
Region region = Region.US_EAST_1;
KinesisAsyncClient client = KinesisAsyncClient.builder()
    .region(region)
    .build();

SubscribeToShardRequest request = SubscribeToShardRequest.builder()
    .consumerARN(CONSUMER_ARN)
    .shardId("arn:aws:kinesis:us-east-1:111122223333:stream/
StockTradeStream")
    .startingPosition(s -> s.type(ShardIteratorType.LATEST)).build();
```

Use the builder interface

You can use the `builder` method to simplify the creation of the [SubscribeToShardResponseHandler](#).

Using the builder, you can set each lifecycle callback with a method call instead of implementing the full interface.

Code

```
private static CompletableFuture<Void> responseHandlerBuilder(KinesisAsyncClient
client, SubscribeToShardRequest request) {
    SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
    .builder()
    .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
    .onComplete(() -> System.out.println("All records stream
successfully"))
    // Must supply some type of subscriber
    .subscriber(e -> System.out.println("Received event - " + e))
    .build();
    return client.subscribeToShard(request, responseHandler);
}
```

For more control of the publisher, you can use the `publisherTransformer` method to customize the publisher.

Code

```
private static CompletableFuture<Void>
responseHandlerBuilderPublisherTransformer(KinesisAsyncClient client,
SubscribeToShardRequest request) {
    SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
    .builder()
    .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
    .publisherTransformer(p -> p.filter(e -> e instanceof
SubscribeToShardEvent).limit(100))
    .subscriber(e -> System.out.println("Received event - " + e))
    .build();
    return client.subscribeToShard(request, responseHandler);
}
```

See the [complete example](#) on GitHub.

Use a custom response handler

For full control of the subscriber and publisher, implement the `SubscribeToShardResponseHandler` interface.

In this example, you implement the `onEventStream` method, which allows you full access to the publisher. This demonstrates how to transform the publisher to event records for printing by the subscriber.

Code

```
private static CompletableFuture<Void>
responseHandlerBuilderClassic(KinesisAsyncClient client, SubscribeToShardRequest
request) {
    SubscribeToShardResponseHandler responseHandler = new
SubscribeToShardResponseHandler() {

        @Override
        public void responseReceived(SubscribeToShardResponse response) {
            System.out.println("Receieved initial response");
        }

        @Override
        public void onEventStream(SdkPublisher<SubscribeToShardEventStream>
publisher) {
            publisher
                // Filter to only SubscribeToShardEvents
                .filter(SubscribeToShardEvent.class)
                // Flat map into a publisher of just records
                .flatMapIterable(SubscribeToShardEvent::records)
                // Limit to 1000 total records
                .limit(1000)
                // Batch records into lists of 25
                .buffer(25)
                // Print out each record batch
                .subscribe(batch -> System.out.println("Record Batch - " +
batch));
        }

        @Override
        public void complete() {
            System.out.println("All records stream successfully");
        }

        @Override
        public void exceptionOccurred(Throwable throwable) {
            System.err.println("Error during stream - " + throwable.getMessage());
        }
    }
}
```

```
};  
return client.subscribeToShard(request, responseHandler);  
}
```

See the [complete example](#) on GitHub.

Use the visitor interface

You can use a [Visitor](#) object to subscribe to specific events you're interested in watching.

Code

```
private static CompletableFuture<Void>  
responseHandlerBuilderVisitorBuilder(KinesisAsyncClient client,  
SubscribeToShardRequest request) {  
    SubscribeToShardResponseHandler.Visitor visitor =  
SubscribeToShardResponseHandler.Visitor  
        .builder()  
        .onSubscribeToShardEvent(e -> System.out.println("Received subscribe to  
shard event " + e))  
        .build();  
    SubscribeToShardResponseHandler responseHandler =  
SubscribeToShardResponseHandler  
        .builder()  
        .onError(t -> System.err.println("Error during stream - " +  
t.getMessage()))  
        .subscriber(visitor)  
        .build();  
    return client.subscribeToShard(request, responseHandler);  
}
```

See the [complete example](#) on GitHub.

Use a custom subscriber

You can also implement your own custom subscriber to subscribe to the stream.

This code snippet shows an example subscriber.

Code

```
private static class MySubscriber implements  
Subscriber<SubscribeToShardEventStream> {
```

```
private Subscription subscription;
private AtomicInteger eventCount = new AtomicInteger(0);

@Override
public void onSubscribe(Subscription subscription) {
    this.subscription = subscription;
    this.subscription.request(1);
}

@Override
public void onNext(SubscribeToShardEventStream shardSubscriptionEventStream) {
    System.out.println("Received event " + shardSubscriptionEventStream);
    if (eventCount.incrementAndGet() >= 100) {
        // You can cancel the subscription at any time if you wish to stop
receiving events.
        subscription.cancel();
    }
    subscription.request(1);
}

@Override
public void onError(Throwable throwable) {
    System.err.println("Error occurred while stream - " +
throwable.getMessage());
}

@Override
public void onComplete() {
    System.out.println("Finished streaming all events");
}
}
```

You can pass the custom subscriber to the `subscribe` method as shown in the following code snippet.

Code

```
private static CompletableFuture<Void>
responseHandlerBuilderSubscriber(KinesisAsyncClient client, SubscribeToShardRequest
request) {
    SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
        .builder()
```

```
        .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
        .subscriber(MySubscriber::new)
        .build();
    return client.subscribeToShard(request, responseHandler);
}
```

See the [complete example](#) on GitHub.

Write data records into a Kinesis data stream

You can use the [KinesisClient](#) object to write data records into a Kinesis data stream by using the `putRecords` method. To successfully invoke this method, create a [PutRecordsRequest](#) object. You pass the name of the data stream to the `streamName` method. Also you must pass the data by using the `putRecords` method (as shown in the following code example).

Imports

```
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.PutRecordRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamRequest;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamResponse;
```

In the following Java code example, notice that **StockTrade** object is used as the data to write to the Kinesis data stream. Before running this example, ensure that you have created the data stream.

Code

```
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.PutRecordRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamRequest;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamResponse;

/**
 * Before running this Java V2 code example, set up your development
```

```
* environment, including your credentials.
*
* For more information, see the following documentation topic:
*
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
*/
public class StockTradesWriter {
    public static void main(String[] args) {
        final String usage = ""

            Usage:
                <streamName>

            Where:
                streamName - The Amazon Kinesis data stream to which records are
written (for example, StockTradeStream)
            """;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String streamName = args[0];
        Region region = Region.US_EAST_1;
        KinesisClient kinesisClient = KinesisClient.builder()
            .region(region)
            .build();

        // Ensure that the Kinesis Stream is valid.
        validateStream(kinesisClient, streamName);
        setStockData(kinesisClient, streamName);
        kinesisClient.close();
    }

    public static void setStockData(KinesisClient kinesisClient, String streamName) {
        try {
            // Repeatedly send stock trades with a 100 milliseconds wait in between.
            StockTradeGenerator stockTradeGenerator = new StockTradeGenerator();

            // Put in 50 Records for this example.
            int index = 50;
            for (int x = 0; x < index; x++) {
                StockTrade trade = stockTradeGenerator.getRandomTrade();
```

```

        sendStockTrade(trade, kinesisClient, streamName);
        Thread.sleep(100);
    }

    } catch (KinesisException | InterruptedException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    System.out.println("Done");
}

private static void sendStockTrade(StockTrade trade, KinesisClient kinesisClient,
    String streamName) {
    byte[] bytes = trade.toJsonAsBytes();

    // The bytes could be null if there is an issue with the JSON serialization by
    // the Jackson JSON library.
    if (bytes == null) {
        System.out.println("Could not get JSON bytes for stock trade");
        return;
    }

    System.out.println("Putting trade: " + trade);
    PutRecordRequest request = PutRecordRequest.builder()
        .partitionKey(trade.getTickerSymbol()) // We use the ticker symbol as
the partition key, explained in
                                                    // the Supplemental Information
section below.
        .streamName(streamName)
        .data(SdkBytes.fromByteArray(bytes))
        .build();

    try {
        kinesisClient.putRecord(request);
    } catch (KinesisException e) {
        System.err.println(e.getMessage());
    }
}

private static void validateStream(KinesisClient kinesisClient, String streamName)
{
    try {
        DescribeStreamRequest describeStreamRequest =
DescribeStreamRequest.builder()

```

```
        .streamName(streamName)
        .build();

        DescribeStreamResponse describeStreamResponse =
kinesisClient.describeStream(describeStreamRequest);

        if (!
describeStreamResponse.streamDescription().streamStatus().toString().equals("ACTIVE"))
    {
            System.err.println("Stream " + streamName + " is not active. Please
wait a few moments and try again.");
            System.exit(1);
        }

    } catch (KinesisException e) {
        System.err.println("Error found while describing the stream " +
streamName);
        System.err.println(e);
        System.exit(1);
    }
}
}
```

See the [complete example](#) on GitHub.

Use a third-party library

You can use other third-party libraries instead of implementing a custom subscriber. This example demonstrates using the RxJava implementation, but you can use any library that implements the Reactive Streams interfaces. See the [RxJava wiki page on Github](#) for more information on that library.

To use the library, add it as a dependency. If you're using Maven, the example shows the POM snippet to use.

POM Entry

```
<dependency>
  <groupId>io.reactivex.rxjava2</groupId>
  <artifactId>rxjava</artifactId>
  <version>2.2.21</version>
</dependency>
```

Imports

```
import java.net.URI;
import java.util.concurrent.CompletableFuture;

import io.reactivex.Flowable;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.http.Protocol;
import software.amazon.awssdk.http.SdkHttpConfigurationOption;
import software.amazon.awssdk.http.nio.netty.NettyNioAsyncHttpClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisAsyncClient;
import software.amazon.awssdk.services.kinesis.model.ShardIteratorType;
import software.amazon.awssdk.services.kinesis.model.StartingPosition;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEvent;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardRequest;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardResponseHandler;
import software.amazon.awssdk.utils.AttributeMap;
```

This example uses RxJava in the `onEventStream` lifecycle method. This gives you full access to the publisher, which can be used to create an Rx Flowable.

Code

```
SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
    .builder()
    .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
    .onEventStream(p -> Flowable.fromPublisher(p)
        .ofType(SubscribeToShardEvent.class)

.flatMapIterable(SubscribeToShardEvent::records)
        .limit(1000)
        .buffer(25)
        .subscribe(e -> System.out.println("Record
batch = " + e)))
    .build();
```

You can also use the `publisherTransformer` method with the Flowable publisher. You must adapt the Flowable publisher to an *SdkPublisher*, as shown in the following example.

Code

```
SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
    .builder()
    .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
    .publisherTransformer(p ->
SdkPublisher.adapt(Flowable.fromPublisher(p).limit(100)))
    .build();
```

See the [complete example](#) on GitHub.

Invoke, list, and delete AWS Lambda functions

This section provides examples of programming with the Lambda service client by using the AWS SDK for Java 2.x.

Topics

- [Invoke a Lambda function](#)
- [List Lambda functions](#)
- [Delete a Lambda function](#)

Invoke a Lambda function

You can invoke a Lambda function by creating a [LambdaClient](#) object and invoking its `invoke` method. Create an [InvokeRequest](#) object to specify additional information such as the function name and the payload to pass to the Lambda function. Function names appear as *arn:aws:lambda:us-east-1:123456789012:function:HelloFunction*. You can retrieve the value by looking at the function in the AWS Management Console.

To pass payload data to a function, create a [SdkBytes](#) object that contains information. For example, in the following code example, notice the JSON data passed to the Lambda function.

Imports

```
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.InvokeRequest;
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.services.lambda.model.InvokeResponse;
import software.amazon.awssdk.services.lambda.model.LambdaException;
```

Code

The following code example demonstrates how to invoke a Lambda function.

```
public static void invokeFunction(LambdaClient awsLambda, String functionName) {

    InvokeResponse res = null ;
    try {
        //Need a SdkBytes instance for the payload
        String json = "{\"Hello \":\"Paris\"}";
        SdkBytes payload = SdkBytes.fromUtf8String(json) ;

        //Setup an InvokeRequest
        InvokeRequest request = InvokeRequest.builder()
            .functionName(functionName)
            .payload(payload)
            .build();

        res = awsLambda.invoke(request);
        String value = res.payload().asUtf8String() ;
        System.out.println(value);

    } catch(LambdaException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

List Lambda functions

Build a [LambdaClient](#) object and invoke its `listFunctions` method. This method returns a [ListFunctionsResponse](#) object. You can invoke this object's `functions` method to return a

list of [FunctionConfiguration](#) objects. You can iterate through the list to retrieve information about the functions. For example, the following Java code example shows how to get each function name.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.services.lambda.model.LambdaException;
import software.amazon.awssdk.services.lambda.model.ListFunctionsResponse;
import software.amazon.awssdk.services.lambda.model.FunctionConfiguration;
import java.util.List;
```

Code

The following Java code example demonstrates how to retrieve a list of function names.

```
public static void listFunctions(LambdaClient awsLambda) {

    try {
        ListFunctionsResponse functionResult = awsLambda.listFunctions();
        List<FunctionConfiguration> list = functionResult.functions();

        for (FunctionConfiguration config: list) {
            System.out.println("The function name is "+config.functionName());
        }

    } catch (LambdaException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Delete a Lambda function

Build a [LambdaClient](#) object and invoke its `deleteFunction` method. Create a [DeleteFunctionRequest](#) object and pass it to the `deleteFunction` method. This object contains information such as the name of the function to delete. Function names appear as *arn:aws:lambda:us-east-1:123456789012:function:HelloFunction*. You can retrieve the value by looking at the function in the AWS Management Console.

Imports

```
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.DeleteFunctionRequest;
import software.amazon.awssdk.services.lambda.model.LambdaException;
```

Code

The following Java code demonstrates how to delete a Lambda function.

```
public static void deleteLambdaFunction(LambdaClient awsLambda, String
functionName ) {
    try {
        DeleteFunctionRequest request = DeleteFunctionRequest.builder()
            .functionName(functionName)
            .build();

        awsLambda.deleteFunction(request);
        System.out.println("The "+functionName +" function was deleted");

    } catch(LambdaException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Work with Amazon S3

This section provides background information for working with Amazon S3 by using the AWS SDK for Java 2.x. This section compliments the [Amazon S3 Java v2 examples](#) presented in the *Code examples* section of this guide.

S3 clients in the AWS SDK for Java 2.x

The AWS SDK for Java 2.x provides different types of S3 clients. The following table shows the differences and can help you decide what is best for your use cases.

Different flavors of Amazon S3 clients

S3 Client	Short description	When to use	Limitation/drawback
<p>AWS CRT-based S3 client</p> <p>Interface: S3AsyncClient</p> <p>Builder: S3CrtAsyncClientBuilder</p>	<ul style="list-style-type: none"> Provides the same asynchronous API operations as the Java-based S3 async client but with greater performance. Requires the <code>aws-crt</code> dependency. Supports automatic parallel transfers (multipart). <p>See the section called "Use a performant S3 client".</p>	<ul style="list-style-type: none"> Your application transfers large objects (> 8MB) and you want maximized performance. You want to upload objects with unknown content length. You want enhanced connection pooling and DNS load balancing, which improves throughput and performance. You want improved transfer reliability in the event of a network failure. Individual failed parts are retried without restarting the transfer from the beginning. 	<ul style="list-style-type: none"> Supports fewer configuration settings than the Java-based S3 clients. Requires an additional dependency.
<p>Java-based S3 async client <i>with</i> multipart enabled</p> <p>Interface: S3AsyncClient</p>	<ul style="list-style-type: none"> Provides an asynchronous API. Supports automatic parallel transfers (multipart) when you enable 	<ul style="list-style-type: none"> Your application transfers large objects and you want improved performance. 	<p>Less performant than the AWS CRT-based S3 client.</p>

S3 Client	Short description	When to use	Limitation/drawback
Builder: S3AsyncClientBuilder	multipart at creation time. See the section called "Configure parallel transfer support" .	<ul style="list-style-type: none"> • you want to upload object with unknown content length. • You want improved transfer reliability in the event of a network failure. Individual failed parts are retried without restarting the transfer from the beginning. • You need configuration options that are not available with the AWS CRT-based S3 client. 	
Java-based S3 async client <i>without</i> multipart enabled Interface: S3AsyncClient Builder: S3AsyncClientBuilder	<ul style="list-style-type: none"> • Provides an asynchronous API. 	<ul style="list-style-type: none"> • You are transferring objects that are less than 8MB. • You want an asynchronous API. 	No performance optimization.
Java-based S3 sync client Interface: S3Client Builder: S3ClientBuilder	<ul style="list-style-type: none"> • Provides a synchronous API. 	<ul style="list-style-type: none"> • You are transferring objects that are less than 8MB. • You want a synchronous API. 	No performance optimization.

Note

From version 2.18.x and onward, the AWS SDK for Java 2.x uses [virtual hosted-style addressing](#) when including an endpoint override. This applies as long as the bucket name is a valid DNS label.

Call the [forcePathStyle](#) method with `true` in your client builder to force the client to use path-style addressing for buckets.

The following example shows a service client configured with an endpoint override and using path-style addressing.

```
S3Client client = S3Client.builder()
    .region(Region.US_WEST_2)
    .endpointOverride(URI.create("https://s3.us-
west-2.amazonaws.com"))
    .forcePathStyle(true)
    .build();
```

- [Work with S3 Event Notifications](#)

Use access points or Multi-Region Access Points

After [Amazon S3 access points](#) or [Multi-Region Access Points](#) are set up, you can call object methods, such as `putObject` and `getObject` and provide the access point identifier instead of a bucket name.

For example, if an access point ARN identifier is `arn:aws:s3:us-west-2:123456789012:accesspoint/test`, you can use the following snippet to call the `putObject` method.

```
Path path = Paths.get(URI.create("file:///temp/file.txt"));

s3Client.putObject(builder -> builder
    .key("myKey")
    .bucket("arn:aws:s3:us-west-2:123456789012:accesspoint/test")
    , path);
```

In place of the ARN string, you can also use the [bucket-style alias](#) of the access point for the bucket parameter.

To use Multi-Region Access Point, replace the bucket parameter with the Multi-Region Access Point ARN that has the following format.

```
arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias
```

Add the following Maven dependency to work with Multi-Region Access Points using the SDK for Java. Search maven central for the [latest version](#).

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>auth-crt</artifactId>
  <version>VERSION</version>
</dependency>
```

Work with Amazon S3 pre-signed URLs

Pre-signed URLs provide temporary access to private S3 objects without requiring users to have AWS credentials or permissions.

For example, assume Alice has access to an S3 object, and she wants to temporarily share access to that object with Bob. Alice can generate a pre-signed GET request to share with Bob so that he can download the object without requiring access to Alice's credentials. You can generate pre-signed URLs for HTTP GET and for HTTP PUT requests.

Generate a pre-signed URL for an object, then download it (GET request)

The following example consists of two parts.

- Part 1: Alice generates the pre-signed URL for an object.
- Part 2: Bob downloads the object by using the pre-signed URL.

Part 1: Generate the URL

Alice already has an object in an S3 bucket. She uses the following code to generate a URL string that Bob can use in a subsequent GET request.

Imports

```
import com.example.s3.util.PresignUrlUtils;
import org.slf4j.Logger;
import software.amazon.awssdk.http.HttpExecuteRequest;
import software.amazon.awssdk.http.HttpExecuteResponse;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.SdkHttpMethod;
import software.amazon.awssdk.http.SdkHttpRequest;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.presigner.S3Presigner;
import software.amazon.awssdk.services.s3.presigner.model.GetObjectPresignRequest;
import software.amazon.awssdk.services.s3.presigner.model.PresignedGetObjectRequest;
import software.amazon.awssdk.utils.IoUtils;

import java.io.ByteArrayOutputStream;
import java.io.File;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URISyntaxException;
import java.net.URL;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;
import java.nio.file.Paths;
import java.time.Duration;
import java.util.UUID;
```

```
/* Create a pre-signed URL to download an object in a subsequent GET request. */
```

```

public String createPresignedGetUrl(String bucketName, String keyName) {
    try (S3Presigner presigner = S3Presigner.create()) {

        GetObjectRequest objectRequest = GetObjectRequest.builder()
            .bucket(bucketName)
            .key(keyName)
            .build();

        GetObjectPresignRequest presignRequest = GetObjectPresignRequest.builder()
            .signatureDuration(Duration.ofMinutes(10)) // The URL will expire
in 10 minutes.
            .getObjectRequest(objectRequest)
            .build();

        PresignedGetObjectRequest presignedRequest =
presigner.presignGetObject(presignRequest);
        logger.info("Presigned URL: [{}]", presignedRequest.url().toString());
        logger.info("HTTP method: [{}]", presignedRequest.httpRequest().method());

        return presignedRequest.url().toExternalForm();
    }
}

```

Part 2: Download the object

Bob uses one of the following three code options to download the object. Alternatively, he could use a browser to perform the GET request.

Use JDK `HttpURLConnection` (since v1.1)

```

/* Use the JDK HttpURLConnection (since v1.1) class to do the download. */
public byte[] useHttpURLConnectionToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); //
Capture the response body to a byte array.

    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
presignedUrl.openConnection();
        connection.setRequestMethod("GET");
        // Download the result of executing the request.
        try (InputStream content = connection.getInputStream()) {
            IoUtils.copy(content, byteArrayOutputStream);
        }
    }
}

```

```

    }
    logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}
return byteArrayOutputStream.toByteArray();
}

```

Use JDK HttpClient (since v11)

```

/* Use the JDK HttpClient (since v11) class to do the download. */
public byte[] useHttpClientToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); //
    Capture the response body to a byte array.

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpResponse<InputStream> response = httpClient.send(requestBuilder
            .uri(presignedUrl.toURI())
            .GET()
            .build(),
            HttpResponse.BodyHandlers.ofInputStream());

        IoUtils.copy(response.body(), byteArrayOutputStream);

        logger.info("HTTP response code is " + response.statusCode());
    } catch (URISyntaxException | InterruptedException | IOException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}

```

Use SdkHttpClient from the SDK for Java

```

/* Use the AWS SDK for Java SdkHttpClient class to do the download. */
public byte[] useSdkHttpClientToPut(String presignedUrlString) {

    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); //
    Capture the response body to a byte array.

```

```
try {
    URL presignedUrl = new URL(presignedUrlString);
    SdkHttpRequest request = SdkHttpRequest.builder()
        .method(SdkHttpMethod.GET)
        .uri(presignedUrl.toURI())
        .build();

    HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
        .request(request)
        .build();

    try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
        HttpExecuteResponse response =
sdkHttpClient.prepareRequest(executeRequest).call();
        response.responseBody().ifPresentOrElse(
            abortableInputStream -> {
                try {
                    IoUtils.copy(abortableInputStream,
byteArrayOutputStream);
                } catch (IOException e) {
                    throw new RuntimeException(e);
                }
            },
            () -> logger.error("No response body."));

        logger.info("HTTP Response code is {}",
response.httpResponse().statusCode());
    }
} catch (URISyntaxException | IOException e) {
    logger.error(e.getMessage(), e);
}
return byteArrayOutputStream.toByteArray();
}
```

See the [complete example](#) and [test](#) on GitHub.

Generate a pre-signed URL for an upload, then upload a file (PUT request)

The following example consists of two parts.

- Part 1: Alice generates the pre-signed URL to upload an object.
- Part 2: Bob uploads a file by using the pre-signed URL.

Part 1: Generate the URL

Alice already has an S3 bucket. She uses the following code to generate a URL string that Bob can use in a subsequent PUT request.

Imports

```
import com.example.s3.util.PresignUrlUtils;
import org.slf4j.Logger;
import software.amazon.awssdk.core.internal.sync.FileContentStreamProvider;
import software.amazon.awssdk.http.HttpExecuteRequest;
import software.amazon.awssdk.http.HttpExecuteResponse;

            .signatureDuration(Duration.ofMinutes(10)) // The URL expires in
10 minutes.
            .putObjectRequest(objectRequest)
            .build();

        PresignedPutObjectRequest presignedRequest =
presigner.presignPutObject(presignRequest);
        String myURL = presignedRequest.url().toString();
        logger.info("Presigned URL to upload a file to: [{}]", myURL);
        logger.info("HTTP method: [{}]", presignedRequest.httpRequest().method());

        return presignedRequest.url().toExternalForm();
    }
}

```

Part 2: Upload a file object

Bob uses one of the following three code options to upload a file.

Use JDK `URLConnection` (since v1.1)

```

/* Use the JDK HttpURLConnection (since v1.1) class to do the upload. */
public void useURLConnectionToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
presignedUrl.openConnection();
        connection.setDoOutput(true);
        metadata.forEach((k, v) -> connection.setRequestProperty("x-amz-meta-" + k,
v));
    }
}

```

```

connection.setRequestMethod("PUT");
OutputStream out = connection.getOutputStream();

try (RandomAccessFile file = new RandomAccessFile(fileToPut, "r");
    FileChannel inChannel = file.getChannel()) {
    ByteBuffer buffer = ByteBuffer.allocate(8192); //Buffer size is 8k

    while (inChannel.read(buffer) > 0) {
        buffer.flip();
        for (int i = 0; i < buffer.limit(); i++) {
            out.write(buffer.get());
        }
        buffer.clear();
    }
} catch (IOException e) {
    logger.error(e.getMessage(), e);
}

out.close();
connection.getResponseCode();
logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}
}

```

Use JDK `HttpClient` (since v11)

```

/* Use the JDK HttpClient (since v11) class to do the upload. */
public void useHttpClientToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    metadata.forEach((k, v) -> requestBuilder.header("x-amz-meta-" + k, v));

    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        final HttpResponse<Void> response = httpClient.send(requestBuilder
            .uri(new URL(presignedUrlString).toURI())
            .PUT(HttpRequest.BodyPublishers.ofFile(Path.of(fileToPut.toURI()))))
    }
}

```

```

        .build(),
        HttpResponse.BodyHandlers.discarding());

    logger.info("HTTP response code is " + response.statusCode());
} catch (URISyntaxException | InterruptedException | IOException e) {
    logger.error(e.getMessage(), e);
}
}

```

Use SdkHttpClient from the SDK for Java

```

/* Use the AWS SDK for Java V2 SdkHttpClient class to do the upload. */
public void useSdkHttpClientToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());

    try {
        URL presignedUrl = new URL(presignedUrlString);

        SdkHttpRequest.Builder requestBuilder = SdkHttpRequest.builder()
            .method(SdkHttpMethod.PUT)
            .uri(presignedUrl.toURI());
        // Add headers
        metadata.forEach((k, v) -> requestBuilder.putHeader("x-amz-meta-" + k, v));
        // Finish building the request.
        SdkHttpRequest request = requestBuilder.build();

        HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
            .request(request)
            .contentStreamProvider(new
FileContentStreamProvider(fileToPut.toPath()))
            .build();

        try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
            HttpExecuteResponse response =
sdkHttpClient.prepareRequest(executeRequest).call();
            logger.info("Response code: {}", response.httpResponse().statusCode());
        }
    } catch (URISyntaxException | IOException e) {
        logger.error(e.getMessage(), e);
    }
}

```

See the [complete example](#) and [test](#) on GitHub.

Cross-Region access for Amazon S3

When you work with Amazon Simple Storage Service (Amazon S3) buckets, you usually know the AWS Region for the bucket. The Region you work with is determined when you create the S3 client.

However, sometimes you might need to work with a specific bucket, but you don't know if it's located in the same Region that's set for the S3 client.

Instead of making more calls to determine the bucket Region, you can use the SDK to enable access to S3 buckets across different Regions.

Setup

Support for cross-Region access became available with version 2.20.111 of the SDK. Use this version or a later one in your Maven build file for the `s3` dependency as shown in the following snippet.

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>s3</artifactId>
  <version>2.27.21</version>
</dependency>
```

Next, when you create your S3 client, enable cross-Region access as shown in the snippet. By default, access is not enabled.

```
S3AsyncClient client = S3AsyncClient.builder()
    .crossRegionAccessEnabled(true)
    .build();
```

How the SDK provides cross-Region access

When you reference an existing bucket in a request, such as when you use the `putObject` method, the SDK initiates a request to the Region configured for the client.

If the bucket does not exist in that specific Region, the error response includes the actual Region where the bucket resides. The SDK then uses the correct Region in a second request.

To optimize future requests to the same bucket, the SDK caches this Region mapping in the client.

Considerations

When you enable cross-Region bucket access, be aware that the first API call might result in increased latency if the bucket isn't in the client's configured Region. However, subsequent calls benefit from cached Region information, resulting in improved performance.

When you enable cross-Region access, access to the bucket is not affected. The user must be authorized to access the bucket in whatever Region it resides.

Data integrity protection with checksums

Amazon Simple Storage Service (Amazon S3) provides the ability to specify a checksum when you upload an object. When you specify a checksum, it is stored with the object and can be validated when the object is downloaded.

Checksums provide an additional layer of data integrity when you transfer files. With checksums, you can verify data consistency by confirming that the received file matches the original file. For more information about checksums with Amazon S3, see the [Amazon Simple Storage Service User Guide](#) including the [supported algorithms](#).

You have the flexibility to choose the algorithm that best fits your needs and let the SDK calculate the checksum. Alternatively, you can provide a pre-computed checksum value by using one of the supported algorithms.

Note

Beginning with version 2.30.0 of the AWS SDK for Java 2.x, the SDK provides default integrity protections by automatically calculating a CRC32 checksum for uploads. The SDK calculates this checksum if you don't provide a precalculated checksum value or if you don't specify an algorithm that the SDK should use to calculate a checksum.

The SDK also provides global settings for data integrity protections that you can set externally, which you can read about in the [AWS SDKs and Tools Reference Guide](#).

We discuss checksums in two request phases: uploading an object and downloading an object.

Upload an object

When you upload an object with the `putObject` method and provide a checksum algorithm, the SDK computes the checksum for the specified algorithm.

The following code snippet shows a request to upload an object with a SHA256 checksum. When the SDK sends the request, it calculates the SHA256 checksum and uploads the object. Amazon S3 validates the integrity of the content by calculating the checksum and comparing it to the checksum provided by the SDK. Amazon S3 then stores the checksum with the object.

```
public void putObjectWithChecksum() {
    s3Client.putObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(ChecksumAlgorithm.SHA256),
        RequestBody.fromString("This is a test"));
}
```

If you don't provide a checksum algorithm with the request, the checksum behavior varies depending on the version of the SDK that you use as shown in the following table.

Checksum behavior when no checksum algorithm is provided

Java SDK version	Checksum behavior
earlier than 2.30.0	The SDK doesn't automatically calculate a CRC-based checksum and provide it in the request.
2.30.0 or later	The SDK uses the CRC32 algorithm to calculate the checksum and provides it in the request. Amazon S3 validates the integrity of the transfer by computing its own CRC32 checksum and compares it to the checksum provided by the SDK. If the checksums match, the checksum is saved with the object.

Use a pre-calculated checksum value

A pre-calculated checksum value provided with the request disables automatic computation by the SDK and uses the provided value instead.

The following example shows a request with a pre-calculated SHA256 checksum.

```
public void putObjectWithPrecalculatedChecksum(String filePath) {
    String checksum = calculateChecksum(filePath, "SHA-256");

    s3Client.putObject((b -> b
        .bucket(bucketName)
        .key(key)
        .checksumSHA256(checksum)),
        RequestBody.fromFile(Paths.get(filePath)));
}
```

If Amazon S3 determines the checksum value is incorrect for the specified algorithm, the service returns an error response.

Multipart uploads

You can also use checksums with multipart uploads.

The SDK for Java 2.x provides two options to use checksums with multipart uploads. The first option uses the `S3TransferManager`.

The following transfer manager example specifies the SHA1 algorithm for the upload.

```
public void multipartUploadWithChecksumTm(String filePath) {
    S3TransferManager transferManager = S3TransferManager.create();
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b
            .bucket(bucketName)
            .key(key)
            .checksumAlgorithm(ChecksumAlgorithm.SHA1))
        .source(Paths.get(filePath))
        .build();
    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    fileUpload.completionFuture().join();
    transferManager.close();
}
```

If you don't provide a checksum algorithm when using the transfer manager for uploads, the SDK automatically calculates and checksum based on the CRC32 algorithm. The SDK performs this calculation for all versions of the SDK.

The second option uses the [S3Client API](#) (or the [S3AsyncClient API](#)) to perform the multipart upload. If you specify a checksum with this approach, you must specify the algorithm to use on the

initiation of the upload. You must also specify the algorithm for each part request and provide the checksum calculated for each part after it is uploaded.

```
public void multipartUploadWithChecksumS3Client(String filePath) {
    ChecksumAlgorithm algorithm = ChecksumAlgorithm.CRC32;

    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse =
s3Client.createMultipartUpload(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(algorithm)); // Checksum specified on initiation.
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
    List<CompletedPart> completedParts = new ArrayList<>();
    ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

    try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
        long fileSize = file.length();
        long position = 0;
        while (position < fileSize) {
            file.seek(position);
            long read = file.getChannel().read(bb);

            bb.flip(); // Swap position and limit before reading from the buffer.
            UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
                .bucket(bucketName)
                .key(key)
                .uploadId(uploadId)
                .checksumAlgorithm(algorithm) // Checksum specified on each part.
                .partNumber(partNumber)
                .build();

            UploadPartResponse partResponse = s3Client.uploadPart(
                uploadPartRequest,
                RequestBody.fromByteBuffer(bb));

            CompletedPart part = CompletedPart.builder()
                .partNumber(partNumber)
                .checksumCRC32(partResponse.checksumCRC32()) // Provide the
calculated checksum.
```

```
        .eTag(partResponse.eTag())
        .build();
    completedParts.add(part);

    bb.clear();
    position += read;
    partNumber++;
}
} catch (IOException e) {
    System.err.println(e.getMessage());
}

// Complete the multipart upload.
s3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)

.multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));
}
```

[Code for the complete examples](#) and [tests](#) are in the GitHub code examples repository.

Download an object

When you use the [getObject](#) method to download an object, the SDK automatically validates the checksum when the `checksumMode` method of the builder for the `GetObjectRequest` is set to `ChecksumMode.ENABLED`.

The request in the following snippet directs the SDK to validate the checksum in the response by calculating the checksum and comparing the values.

```
public GetObjectResponse getObjectWithChecksum() {
    return s3Client.getObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumMode(ChecksumMode.ENABLED))
        .response();
}
```

If the object wasn't uploaded with a checksum, no validation takes place.

Use a performant S3 client: AWS CRT-based S3 client

The AWS CRT-based S3 client—built on top of the [AWS Common Runtime \(CRT\)](#)—is an alternative S3 asynchronous client. It transfers objects to and from Amazon Simple Storage Service (Amazon S3) with enhanced performance and reliability by automatically using Amazon S3's [multipart upload API](#) and [byte-range fetches](#).

The AWS CRT-based S3 client improves transfer reliability in case there is a network failure. Reliability is improved by retrying individual failed parts of a file transfer without restarting the transfer from the beginning.

In addition, the AWS CRT-based S3 client offers enhanced connection pooling and Domain Name System (DNS) load balancing, which also improves throughput.

You can use the AWS CRT-based S3 client in place of the SDK's standard S3 asynchronous client and take advantage of its improved throughput right away.

AWS CRT-based components in the SDK

The AWS CRT-based S3 client, described in this topic, and the AWS CRT-based *HTTP* client are different components in the SDK.

The **AWS CRT-based S3 client** is an implementation of the [S3AsyncClient](#) interface and is used for working with the Amazon S3 service. It is an alternative to the Java-based implementation of the `S3AsyncClient` interface and offers several benefits.

The [AWS CRT-based HTTP client](#) is an implementation of the [SdkAsyncHttpClient](#) interface and is used for general HTTP communication. It is an alternative to the Netty implementation of the `SdkAsyncHttpClient` interface and offers several advantages.

Although both components use libraries from the [AWS Common Runtime](#), the AWS CRT-based S3 client uses the [aws-c-s3 library](#) and supports the [S3 multipart upload API](#) features. Since the AWS CRT-based HTTP client is meant for general purpose use, it does not support the S3 multipart upload API features.

Add dependencies to use the AWS CRT-based S3 client

To use the AWS CRT-based S3 client, add the following two dependencies to your Maven project file. The example shows the minimum versions to use. Search the Maven central repository for the most recent versions of the [s3](#) and [aws-crt](#) artifacts.

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>s3</artifactId>
  <version>2.27.21</version>
</dependency>
<dependency>
  <groupId>software.amazon.awssdk.crt</groupId>
  <artifactId>aws-crt</artifactId>
  <version>0.30.11</version>
</dependency>
```

Create an instance of the AWS CRT-based S3 client

Create an instance of the AWS CRT-based S3 client with default settings as shown in the following code snippet.

```
S3AsyncClient s3AsyncClient = S3AsyncClient.crtCreate();
```

To configure the client, use the AWS CRT client builder. You can switch from the standard S3 asynchronous client to AWS CRT-based client by changing the builder method.

```
import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;

S3AsyncClient s3AsyncClient =
    S3AsyncClient.crtBuilder()
        .credentialsProvider(DefaultCredentialsProvider.create())
        .region(Region.US_WEST_2)
        .targetThroughputInGbps(20.0)
        .minimumPartSizeInBytes(8 * 1025 * 1024L)
        .build();
```

Note

Some of the settings in the standard builder might not be currently supported in the AWS CRT client builder. Get the standard builder by calling `S3AsyncClient#builder()`.

Use the AWS CRT-based S3 client

Use the AWS CRT-based S3 client to call Amazon S3 API operations. The following example demonstrates the [PutObject](#) and [GetObject](#) operations available through the AWS SDK for Java.

```
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.core.async.AsyncResponseTransformer;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.GetObjectResponse;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;

S3AsyncClient s3Client = S3AsyncClient.crtCreate();

// Upload a local file to Amazon S3.
PutObjectResponse putObjectResponse =
    s3Client.putObject(req -> req.bucket(<BUCKET_NAME>)
        .key(<KEY_NAME>),
        AsyncRequestBody.fromFile(Paths.get(<FILE_NAME>)))
        .join();

// Download an object from Amazon S3 to a local file.
GetObjectResponse getObjectResponse =
    s3Client.getObject(req -> req.bucket(<BUCKET_NAME>)
        .key(<KEY_NAME>),
        AsyncResponseTransformerToFile(Paths.get(<FILE_NAME>)))
        .join();
```

Configuration limitations

The AWS CRT-based S3 client and Java-based S3 async client [provide comparable features](#), with the AWS CRT-based S3 client offering a performance edge. However, the AWS CRT-based S3 client lacks configuration settings that the Java-based S3 async client has. These settings include:

- *Client-level configuration*: API call attempt timeout, compression execution interceptors, metric publishers, custom execution attributes, custom advanced options, custom scheduled executor service, custom headers
- *Request-level configuration*: custom signers, credentials providers, API call attempt timeout

For a full listing of the configuration differences, see the API reference.

Java-based S3 async client	AWS CRT-based S3 client
Client-level configurations <ul style="list-style-type: none"> • ClientOverrideConfiguration.Builder 	Client-level configurations <ul style="list-style-type: none"> • S3CrtAsyncClientBuilder
Request-level configurations <ul style="list-style-type: none"> • RequestOverrideConfiguration.Builder • AwsRequestOverrideConfiguration.Builder 	No request-level configurations

Configure the Java-based S3 async client to use parallel transfers

Since version 2.27.5, the standard Java-based S3 async client supports automatic parallel transfers (multipart uploads and downloads). You configure support for parallel transfers when you create the Java-based S3 async client.

This section shows how to enable parallel transfers and how to customize the configuration.

Create an instance of `S3AsyncClient`

When you create an `S3AsyncClient` instance without calling any of the `multipart*` methods on the [builder](#), parallel transfers are not enabled. Each of following statements create a Java-based S3 async client without support for multipart uploads and downloads.

Create *without* multipart support

Example

```
import software.amazon.awssdk.auth.credentials.ProcessCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;

S3AsyncClient s3Client = S3AsyncClient.create();

S3AsyncClient s3Client2 = S3AsyncClient.builder().build();

S3AsyncClient s3Client3 = S3AsyncClient.builder()
```

```
.credentialsProvider(ProcessCredentialsProvider.builder().build())
.region(Region.EU_NORTH_1)
.build();
```

Create *with* multipart support

To enable parallel transfers with default settings, call the `multipartEnabled` on the builder and pass in `true` as shown in the following example.

Example

```
S3AsyncClient s3AsyncClient2 = S3AsyncClient.builder()
    .multipartEnabled(true)
    .build();
```

The default value is 8 MiB for `thresholdInBytes` and `minimumPartSizeInBytes` settings.

If you customize the multipart settings, parallel transfers are automatically enabled as shown in the following.

Example

```
import software.amazon.awssdk.services.s3.S3AsyncClient;
import static software.amazon.awssdk.transfer.s3.SizeConstant.MB;

S3AsyncClient s3AsyncClient2 = S3AsyncClient.builder()
    .multipartConfiguration(b -> b
        .thresholdInBytes(16 * MB)
        .minimumPartSizeInBytes(10 * MB))
    .build();
```

Transfer files and directories with the Amazon S3 Transfer Manager

The Amazon S3 Transfer Manager is an open source, high level file transfer utility for the AWS SDK for Java 2.x. Use it to transfer files and directories to and from Amazon Simple Storage Service (Amazon S3).

When built on top of the [AWS CRT-based S3 client](#) or the [standard Java-based S3 async client with multipart enabled](#), the S3 Transfer Manager can take advantage of performance improvements such as the [multipart upload API](#) and [byte-range fetches](#).

With the S3 Transfer Manager, you can also monitor a transfer's progress in real time and pause the transfer for later execution.

Get started

Add dependencies to your build file

To use the S3 Transfer Manager with enhanced multipart performance, configure your build file with necessary dependencies.

Use the AWS CRT-based S3 client

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.27.211</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>s3-transfer-manager</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk.crt</groupId>
    <artifactId>aws-crt</artifactId>
    <version>0.29.1432</version>
  </dependency>
</dependencies>
```

¹ [Latest version.](#) ² [Latest version.](#)

Use the Java-based S3 async client

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
```

```
<artifactId>bom</artifactId>
<version>2.27.211</version>
<type>pom</type>
<scope>import</scope>
</dependency>
</dependencies>
</dependencyManagement>
<dependencies>
<dependency>
<groupId>software.amazon.awssdk</groupId>
<artifactId>s3-transfer-manager</artifactId>
</dependency>
</dependencies>
```

¹ [Latest version](#).

Create an instance of the S3 Transfer Manager

To enable parallel transfer, you must pass in a AWS CRT-based S3 client OR a Java-based S3 async client with multipart enabled. The following examples shows how to configure a S3 Transfer Manager with custom settings.

Use the AWS CRT-based S3 client

```
S3AsyncClient s3AsyncClient = S3AsyncClient.crtBuilder()
    .credentialsProvider(DefaultCredentialsProvider.create())
    .region(Region.US_EAST_1)
    .targetThroughputInGbps(20.0)
    .minimumPartSizeInBytes(8 * MB)
    .build();

S3TransferManager transferManager = S3TransferManager.builder()
    .s3Client(s3AsyncClient)
    .build();
```

Use the Java-based S3 async client

If the `aws-crt` dependency is not included in the build file, the S3 Transfer Manager is built on top of the standard Java-based S3 async client used in the SDK for Java 2.x.

Custom configuration of S3 client - requires multipart enabled

```
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .multipartEnabled(true)
    .credentialsProvider(DefaultCredentialsProvider.create())
    .region(Region.US_EAST_1)
    .targetThroughputInGbps(20.0)
    .minimumPartSizeInBytes(8 * MB)
    .build();

S3TransferManager transferManager = S3TransferManager.builder()
    .s3Client(s3AsyncClient)
    .build();
```

No configuration of S3 client - multipart support automatically enabled

```
S3TransferManager transferManager = S3TransferManager.create();
```

Upload a file to an S3 bucket

The following example shows a file upload example along with the optional use of a [LoggingTransferListener](#), which logs the progress of the upload.

To upload a file to Amazon S3 using the S3 Transfer Manager, pass an [UploadFileRequest](#) object to the S3TransferManager's [uploadFile](#) method.

The [FileUpload](#) object returned from the `uploadFile` method represents the upload process. After the request finishes, the [CompletedFileUpload](#) object contains information about the upload.

```
public String uploadFile(S3TransferManager transferManager, String bucketName,
                        String key, URI filePathURI) {
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b.bucket(bucketName).key(key))
        .source(Paths.get(filePathURI))
        .build();

    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);

    CompletedFileUpload uploadResult = fileUpload.completionFuture().join();
    return uploadResult.response().eTag();
}
```

Imports

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileUpload;
import software.amazon.awssdk.transfer.s3.model.FileUpload;
import software.amazon.awssdk.transfer.s3.model.UploadFileRequest;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;
import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Paths;
import java.util.UUID;
```

Download a file from an S3 bucket

The following example shows a download example along with the optional use of a [LoggingTransferListener](#), which logs the progress of the download.

To download an object from an S3 bucket using the S3 Transfer Manager, build a [DownloadFileRequest](#) object and pass it to the [downloadFile](#) method.

The [FileDownload](#) object returned by the S3TransferManager's `downloadFile` method represents the file transfer. After the download completes, the [CompletedFileDownload](#) contains access to information about the download.

```
public Long downloadFile(S3TransferManager transferManager, String bucketName,
                        String key, String downloadedFilePath) {
    DownloadFileRequest downloadFileRequest = DownloadFileRequest.builder()
        .getObjectRequest(b -> b.bucket(bucketName).key(key))
        .destination(Paths.get(downloadedFilePath))
        .build();

    FileDownload downloadFile = transferManager.downloadFile(downloadFileRequest);

    CompletedFileDownload downloadResult = downloadFile.completionFuture().join();
    logger.info("Content length [{}]", downloadResult.response().contentLength());
    return downloadResult.response().contentLength();
}
```

Imports

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileDownload;
import software.amazon.awssdk.transfer.s3.model.DownloadFileRequest;
import software.amazon.awssdk.transfer.s3.model.FileDownload;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;

import java.io.IOException;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Files;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.util.UUID;
```

Copy an Amazon S3 object to another bucket

The following example shows how to copy an object with the S3 Transfer Manager.

To begin the copy of an object from an S3 bucket to another bucket, create a basic [CopyObjectRequest](#) instance.

Next, wrap the basic `CopyObjectRequest` in a [CopyRequest](#) that can be used by the S3 Transfer Manager.

The `Copy` object returned by the `S3TransferManager`'s `copy` method represents the copy process. After the copy process completes, the [CompletedCopy](#) object contains details about the response.

```
public String copyObject(S3TransferManager transferManager, String bucketName,
    String key, String destinationBucket, String destinationKey) {
    CopyObjectRequest copyObjectRequest = CopyObjectRequest.builder()
        .sourceBucket(bucketName)
        .sourceKey(key)
        .destinationBucket(destinationBucket)
        .destinationKey(destinationKey)
        .build();
```

```

CopyRequest copyRequest = CopyRequest.builder()
    .copyObjectRequest(copyObjectRequest)
    .build();

Copy copy = transferManager.copy(copyRequest);

CompletedCopy completedCopy = copy.completionFuture().join();
return completedCopy.response().copyObjectResult().eTag();
}

```

Note

To perform a cross-Region copy with the S3 Transfer Manager, enable `crossRegionAccessEnabled` on the AWS CRT-based S3 client builder as shown in the following snippet.

```

S3AsyncClient s3AsyncClient = S3AsyncClient.crtBuilder()
    .crossRegionAccessEnabled(true)
    .build();

S3TransferManager transferManager = S3TransferManager.builder()
    .s3Client(s3AsyncClient)
    .build();

```

Imports

```

import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import java.util.UUID;

```

Upload a local directory to an S3 bucket

The following example demonstrates how you can upload a local directory to S3.

Start by calling the [uploadDirectory](#) method of the `S3TransferManager` instance, passing in an [UploadDirectoryRequest](#).

The [DirectoryUpload](#) object represents the upload process, which generates a [CompletedDirectoryUpload](#) when the request completes. The `CompletedDirectoryUpload` object contains information about the results of the transfer, including which files failed to transfer.

```
public Integer uploadDirectory(S3TransferManager transferManager,
    URI sourceDirectory, String bucketName) {
    DirectoryUpload directoryUpload =
transferManager.uploadDirectory(UploadDirectoryRequest.builder()
    .source(Paths.get(sourceDirectory))
    .bucket(bucketName)
    .build());

    CompletedDirectoryUpload completedDirectoryUpload =
directoryUpload.completionFuture().join();
    completedDirectoryUpload.failedTransfers()
        .forEach(fail -> logger.warn("Object [{}] failed to transfer",
fail.toString()));
    return completedDirectoryUpload.failedTransfers().size();
}
```

Imports

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedDirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.DirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.UploadDirectoryRequest;

import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Paths;
import java.util.UUID;
```

Download S3 bucket objects to a local directory

You can download the objects in an S3 bucket to a local directory as shown in the following example.

To download the objects in an S3 bucket to a local directory, begin by calling the [downloadDirectory](#) method of the Transfer Manager, passing in a [DownloadDirectoryRequest](#).

The [DirectoryDownload](#) object represents the download process, which generates a [CompletedDirectoryDownload](#) when the request completes. The [CompletedDirectoryDownload](#) object contains information about the results of the transfer, including which files failed to transfer.

```
public Integer downloadObjectsToDirectory(S3TransferManager transferManager,
    URI destinationPathURI, String bucketName) {
    DirectoryDownload directoryDownload =
transferManager.downloadDirectory(DownloadDirectoryRequest.builder()
    .destination(Paths.get(destinationPathURI))
    .bucket(bucketName)
    .build());
    CompletedDirectoryDownload completedDirectoryDownload =
directoryDownload.completionFuture().join();

    completedDirectoryDownload.failedTransfers()
        .forEach(fail -> logger.warn("Object [{}] failed to transfer",
fail.toString()));
    return completedDirectoryDownload.failedTransfers().size();
}
```

Imports

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedDirectoryDownload;
import software.amazon.awssdk.transfer.s3.model.DirectoryDownload;
import software.amazon.awssdk.transfer.s3.model.DownloadDirectoryRequest;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;
```

```
import java.nio.file.Files;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.util.HashSet;
import java.util.Set;
import java.util.UUID;
import java.util.stream.Collectors;
```

[GitHub contains the complete](#) code for all examples on this page.

Work with S3 Event Notifications

To help you monitor activity in your buckets, Amazon S3 can send notifications when certain events happen. The Amazon S3 User Guide provides information on the [notifications that a bucket can send out](#).

You can set up a bucket to send events to four possible destinations using the SDK for Java:

- Amazon Simple Notification Service topics
- Amazon Simple Queue Service queues
- AWS Lambda functions
- Amazon EventBridge

When you setup up a bucket to send events to EventBridge, you have the ability to configure an EventBridge rule to fanout the same event to multiple destinations. When you configure your bucket to send directly to one of the first three destinations, only one destination type can be specified for each event.

In the next section, you'll see how to configure a bucket using the SDK for Java to send S3 Event Notifications in two ways: directly to an Amazon SQS queue and to EventBridge.

The last section shows you how to use the S3 Event Notifications API to work with notifications in an object-oriented way.

Configure a bucket to send directly to a destination

The following example configures a bucket to send notifications when *object create* events or *object tagging* events occur against a bucket.

```

static void processS3Events(String bucketName, String queueArn) {
    // Configure the bucket to send Object Created and Object Tagging notifications to
    // an existing SQS queue.
    s3Client.putBucketNotificationConfiguration(b -> b
        .notificationConfiguration(ncb -> ncb
            .queueConfigurations(qcb -> qcb
                .events(Event.S3_OBJECT_CREATED, Event.S3_OBJECT_TAGGING)
                .queueArn(queueArn)))
            .bucket(bucketName)
        );
}

```

The code shown above sets up one queue to receive two types of events. Conveniently, the `queueConfigurations` method allows you to set multiple queue destinations if needed. Also, in the `notificationConfiguration` method you can set additional destinations, such as one or more Amazon SNS topics or one or more Lambda functions. The following snippet shows an example with two queues and three types of destinations.

```

s3Client.putBucketNotificationConfiguration(b -> b
    .notificationConfiguration(ncb -> ncb
        .queueConfigurations(qcb -> qcb
            .events(Event.S3_OBJECT_CREATED,
                Event.S3_OBJECT_TAGGING)
            .queueArn(queueArn),
            qcb2 -> qcb2.<...>)
        .topicConfigurations(tcb -> tcb.<...>)
        .lambdaFunctionConfigurations(lfcb -> lfcb.<...>))
    .bucket(bucketName)
);

```

The Code Examples GitHub repository contains the [complete example](#) to send S3 event notifications directly to a queue.

Configure a bucket to send to EventBridge

The following example configures a bucket to send notifications to EventBridge.

```

public static String setBucketNotificationToEventBridge(String bucketName) {
    // Enable bucket to emit S3 Event notifications to EventBridge.
    s3Client.putBucketNotificationConfiguration(b -> b
        .bucket(bucketName)
    );
}

```

```

        .notificationConfiguration(b1 -> b1
            .eventBridgeConfiguration(SdkBuilder::build))
    .build());

```

When you configure a bucket to send events to EventBridge, you simply indicate the EventBridge destination, not the types of events nor the ultimate destination that EventBridge will dispatch to. You configure the ultimate targets and event types by using the Java SDK's EventBridge client.

The following code shows how to configure EventBridge to fan out *object created* events to a topic and a queue.

```

public static String configureEventBridge(String topicArn, String queueArn) {
    try {
        // Create an EventBridge rule to route Object Created notifications.
        PutRuleRequest putRuleRequest = PutRuleRequest.builder()
            .name(RULE_NAME)
            .eventPattern("""
                {
                    "source": ["aws.s3"],
                    "detail-type": ["Object Created"],
                    "detail": {
                        "bucket": {
                            "name": ["%s"]
                        }
                    }
                }
            """).formatted(bucketName)
            .build();

        // Add the rule to the default event bus.
        PutRuleResponse putRuleResponse = eventBridgeClient.putRule(putRuleRequest)
            .whenComplete((r, t) -> {
                if (t != null) {
                    logger.error("Error creating event bus rule: " +
t.getMessage(), t);
                    throw new RuntimeException(t.getCause().getMessage(), t);
                }
                logger.info("Event bus rule creation request sent successfully.
ARN is: {}", r.ruleArn());
            }).join();

        // Add the existing SNS topic and SQS queue as targets to the rule.
        eventBridgeClient.putTargets(b -> b

```

```
        .eventBusName("default")
        .rule(RULE_NAME)
        .targets(List.of (
            Target.builder()
                .arn(queueArn)
                .id("Queue")
                .build(),
            Target.builder()
                .arn(topicArn)
                .id("Topic")
                .build()
        )
        ).join();
    return putRuleResponse.ruleArn();
} catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return null;
}
```

To work with EventBridge in your Java code, add a dependency on the `eventbridge` artifact to your `Maven pom.xml` file.

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>eventbridge</artifactId>
</dependency>
```

The Code Examples GitHub repository contains the [complete example](#) to send S3 event notifications to EventBridge and then to a topic and queue.

Use the S3 Event Notifications API to process events

After a destination receives S3 notification events, you can process them in an object-oriented way by using the S3 Event Notifications API. You can use the S3 Event Notifications API to work with event notifications that are dispatched directly to a target (as shown in the [first example](#)), but not with notifications routed through EventBridge. S3 event notifications sent by buckets to EventBridge contain a [different structure](#) that the S3 Event Notifications API does not currently handle.

Add dependency

The S3 Event Notifications API was released with version 2.25.11 of the SDK for Java 2.x.

To use the S3 Event Notifications API, add the required dependency element to your Maven `pom.xml` as shown in the following snippet.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.X.X1</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>s3-event-notifications</artifactId>
  </dependency>
</dependencies>
```

¹ [Latest version.](#)

Use the `S3EventNotification` class

Create an `S3EventNotification` instance from a JSON string

To convert a JSON string into an `S3EventNotification` object, use the static methods of the `S3EventNotification` class as shown in the following example.

```
import software.amazon.awssdk.eventnotifications.s3.model.S3EventNotification
import software.amazon.awssdk.eventnotifications.s3.model.S3EventNotificationRecord
import software.amazon.awssdk.services.sqs.model.Message;

public class S3EventNotificationExample {
  ...

  void receiveMessage(Message message) {
    // Message received from SQSClient.
  }
}
```

```
String sqsEventBody = message.body();
S3EventNotification s3EventNotification =
S3EventNotification.fromJson(sqsEventBody);

// Use getRecords() to access all the records in the notification.

List<S3EventNotificationRecord> records = s3EventNotification.getRecords();

S3EventNotificationRecord record = records.stream().findFirst();
// Use getters on the record to access individual attributes.
String awsRegion = record.getAwsRegion();
String eventName = record.getEventName();
String eventSource = record.getEventSource();

}
}
```

In this example, the `fromJson` method converts the JSON string into an `S3EventNotification` object. Missing fields in the JSON string will result in `null` values in the corresponding Java object fields and any extra fields in the JSON will be ignored.

Other APIs for an event notification record can be found in API reference for [S3EventNotificationRecord](#).

Convert an `S3EventNotification` instance to a JSON string

Use the `toJson` (or `toJsonPretty`) method to convert an `S3EventNotification` object into a JSON string as shown in the following example.

```
import software.amazon.awssdk.eventnotifications.s3.model.S3EventNotification

public class S3EventNotificationExample {
    ...

    void toJsonString(S3EventNotification event) {

        String json = event.toJson();
        String jsonPretty = event.toJsonPretty();

        System.out.println("JSON: " + json);
        System.out.println("Pretty JSON: " + jsonPretty);

    }
}
```

```
}
```

Fields for `GlacierEventData`, `ReplicationEventData`, `IntelligentTieringEventData`, and `LifecycleEventData` are excluded from the JSON if they are null. Other null fields will be serialized as null.

The following shows example output of the `toJsonPretty` method for an S3 object tagging event.

```
{
  "Records" : [ {
    "eventVersion" : "2.3",
    "eventSource" : "aws:s3",
    "awsRegion" : "us-east-1",
    "eventTime" : "2024-07-19T20:09:18.551Z",
    "eventName" : "ObjectTagging:Put",
    "userIdentity" : {
      "principalId" : "AWS:XXXXXXXXXXXX"
    },
    "requestParameters" : {
      "sourceIPAddress" : "XXX.XX.XX.XX"
    },
    "responseElements" : {
      "x-amz-request-id" : "XXXXXXXXXXXX",
      "x-amz-id-2" : "XXXXXXXXXXXX"
    },
    "s3" : {
      "s3SchemaVersion" : "1.0",
      "configurationId" : "XXXXXXXXXXXX",
      "bucket" : {
        "name" : "DOC-EXAMPLE-BUCKET",
        "ownerIdentity" : {
          "principalId" : "XXXXXXXXXXXX"
        },
        "arn" : "arn:aws:s3:::XXXXXXXXXXXX"
      },
      "object" : {
        "key" : "akey",
        "size" : null,
        "eTag" : "XXXXXXXXXX",
        "versionId" : null,
        "sequencer" : null
      }
    }
  }
}
```

```
    }  
  } ]  
}
```

A [complete example](#) is available in GitHub that shows how to use the API to work with notifications received by an Amazon SQS queue.

Work with Amazon Simple Notification Service

With Amazon Simple Notification Service, you can easily push real-time notification messages from your applications to subscribers over multiple communication channels. This topic describes how to perform some of the basic functions of Amazon SNS.

Create a topic

A **topic** is a logical grouping of communication channels that defines which systems to send a message to, for example, fanning out a message to AWS Lambda and an HTTP webhook. You send messages to Amazon SNS, then they're distributed to the channels defined in the topic. This makes the messages available to subscribers.

To create a topic, first build a [CreateTopicRequest](#) object, with the name of the topic set using the `name()` method in the builder. Then, send the request object to Amazon SNS by using the `createTopic()` method of the [SnsClient](#). You can capture the result of this request as a [CreateTopicResponse](#) object, as demonstrated in the following code snippet.

Imports

```
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.sns.SnsClient;  
import software.amazon.awssdk.services.sns.model.CreateTopicRequest;  
import software.amazon.awssdk.services.sns.model.CreateTopicResponse;  
import software.amazon.awssdk.services.sns.model.SnsException;
```

Code

```
public static String createSNSTopic(SnsClient snsClient, String topicName ) {  
  
    CreateTopicResponse result = null;  
    try {
```

```
        CreateTopicRequest request = CreateTopicRequest.builder()
            .name(topicName)
            .build();

        result = snsClient.createTopic(request);
        return result.topicArn();
    } catch (SnsException e) {

        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

See the [complete example](#) on GitHub.

List your Amazon SNS topics

To retrieve a list of your existing Amazon SNS topics, build a [ListTopicsRequest](#) object. Then, send the request object to Amazon SNS by using the `listTopics()` method of the `SnsClient`. You can capture the result of this request as a [ListTopicsResponse](#) object.

The following code snippet prints out the HTTP status code of the request and a list of Amazon Resource Names (ARNs) for your Amazon SNS topics.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ListTopicsRequest;
import software.amazon.awssdk.services.sns.model.ListTopicsResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

Code

```
public static void listSNSTopics(SnsClient snsClient) {

    try {
        ListTopicsRequest request = ListTopicsRequest.builder()
            .build();

        ListTopicsResponse result = snsClient.listTopics(request);
    }
```

```
        System.out.println("Status was " + result.sdkHttpResponse().statusCode() +
"\n\nTopics\n\n" + result.topics());

    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Subscribe an endpoint to a topic

After you create a topic, you can configure which communication channels will be endpoints for that topic. Messages are distributed to these endpoints after Amazon SNS receives them.

To configure a communication channel as an endpoint for a topic, subscribe that endpoint to the topic. To start, build a [SubscribeRequest](#) object. Specify the communication channel (for example, lambda or email) as the `protocol()`. Set the `endpoint()` to the relevant output location (for example, the ARN of a Lambda function or an email address), and then set the ARN of the topic to which you want to subscribe as the `topicArn()`. Send the request object to Amazon SNS by using the `subscribe()` method of the `SnsClient`. You can capture the result of this request as a [SubscribeResponse](#) object.

The following code snippet shows how to subscribe an email address to a topic.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.SubscribeRequest;
import software.amazon.awssdk.services.sns.model.SubscribeResponse;
```

Code

```
public static void subEmail(SnsClient snsClient, String topicArn, String email) {

    try {
        SubscribeRequest request = SubscribeRequest.builder()
            .protocol("email")
```

```
        .endpoint(email)
        .returnSubscriptionArn(true)
        .topicArn(topicArn)
        .build();

        SubscribeResponse result = snsClient.subscribe(request);
        System.out.println("Subscription ARN: " + result.subscriptionArn() + "\n\n"
            + "Status is " + result.sdkHttpResponse().statusCode());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Publish a message to a topic

After you have a topic and one or more endpoints configured for it, you can publish a message to it. To start, build a [PublishRequest](#) object. Specify the message () to send, and the ARN of the topic (topicArn()) to send it to. Then, send the request object to Amazon SNS by using the publish() method of the SnsClient. You can capture the result of this request as a [PublishResponse](#) object.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.PublishRequest;
import software.amazon.awssdk.services.sns.model.PublishResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

Code

```
public static void pubTopic(SnsClient snsClient, String message, String topicArn) {

    try {
        PublishRequest request = PublishRequest.builder()
            .message(message)
            .topicArn(topicArn)
            .build();
```

```
        PublishResponse result = snsClient.publish(request);
        System.out.println(result.messageId() + " Message sent. Status is " +
result.sdkHttpResponse().statusCode());

    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Unsubscribe an endpoint from a topic

You can remove the communication channels configured as endpoints for a topic. After doing that, the topic itself continues to exist and distribute messages to any other endpoints configured for that topic.

To remove a communication channel as an endpoint for a topic, unsubscribe that endpoint from the topic. To start, build an [UnsubscribeRequest](#) object and set the ARN of the topic you want to unsubscribe from as the `subscriptionArn()`. Then send the request object to SNS by using the `unsubscribe()` method of the `SnsClient`. You can capture the result of this request as an [UnsubscribeResponse](#) object.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.UnsubscribeRequest;
import software.amazon.awssdk.services.sns.model.UnsubscribeResponse;
```

Code

```
public static void unSub(SnsClient snsClient, String subscriptionArn) {

    try {
        UnsubscribeRequest request = UnsubscribeRequest.builder()
            .subscriptionArn(subscriptionArn)
            .build();
```

```
        UnsubscribeResponse result = snsClient.unsubscribe(request);

        System.out.println("\n\nStatus was " +
            result.sdkHttpResponse().statusCode()
            + "\n\nSubscription was removed for " + request.subscriptionArn());

    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

Delete a topic

To delete an Amazon SNS topic, first build a [DeleteTopicRequest](#) object with the ARN of the topic set as the `topicArn()` method in the builder. Then send the request object to Amazon SNS by using the `deleteTopic()` method of the `SnsClient`. You can capture the result of this request as a [DeleteTopicResponse](#) object, as demonstrated in the following code snippet.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.DeleteTopicRequest;
import software.amazon.awssdk.services.sns.model.DeleteTopicResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

Code

```
public static void deleteSNSTopic(SnsClient snsClient, String topicArn ) {

    try {
        DeleteTopicRequest request = DeleteTopicRequest.builder()
            .topicArn(topicArn)
            .build();

        DeleteTopicResponse result = snsClient.deleteTopic(request);
        System.out.println("\n\nStatus was " +
            result.sdkHttpResponse().statusCode());
    }
```

```
    } catch (SnsException e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

See the [complete example](#) on GitHub.

For more information, see the [Amazon Simple Notification Service Developer Guide](#).

Work with Amazon Simple Queue Service

This section provides examples of programming [Amazon Simple Queue Service](#) using the AWS SDK for Java 2.x.

The following examples include only the code needed to demonstrate each technique. The [complete example code is available on GitHub](#). From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

- [Send, receive, and delete Amazon Simple Queue Service messages](#)

Use automatic request batching for Amazon SQS with the AWS SDK for Java 2.x

The Automatic Request Batching API for Amazon SQS is a high-level library that provides an efficient way to batch and buffer requests for SQS operations. By using the batching API, you reduce the number of requests to SQS, which improves throughput and minimizes costs.

Because the batch API methods match the [SqsAsyncClient](#) methods—`sendMessage`, `changeMessageVisibility`, `deleteMessage`, `receiveMessage`—you can use the batch API as a drop-in replacement with minimal changes.

This topic gives you an overview of how to configure and work with the Automatic Request Batching API for Amazon SQS.

Check prerequisites

You need to use version 2.28.0 or later of the SDK for Java 2.x to have access to the batching API. Your Maven pom.xml should at least contain the following elements.

```
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.28.231</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>sqs</artifactId>
  </dependency>
</dependencies>
```

¹ [Latest version](#)

Create a batch manager

The automatic request batching API is implemented by the [SqsAsyncBatchManager](#) interface. You can create an instance of the manager a couple ways.

Default configuration by using SqsAsyncClient

The simplest way you can create a batch manager is to call the `batchManager` factory method on an existing [SqsAsyncClient](#) instance. The simple approach is shown in the following snippet.

```
SqsAsyncClient asyncClient = SqsAsyncClient.create();
SqsAsyncBatchManager sqsAsyncBatchManager = asyncClient.batchManager();
```

When you use this approach, the `SqsAsyncBatchManager` instance uses the default values that are shown in the table in the [the section called "Configuration settings"](#) section. Additionally, the

`SqsAsyncBatchManager` instance uses the `ExecutorService` of the `SqsAsyncClient` instance that it was created from.

Custom configuration by using `SqsAsyncBatchManager.Builder`

For more advanced use cases, you can customize the batch manager using the [`SqsAsyncBatchManager.Builder`](#). By using this approach to create a `SqsAsyncBatchManager` instance, you can fine tune the batching behavior. The following snippet shows an example of how to use the builder to customize batching behavior.

```
SqsAsyncBatchManager batchManager = SqsAsyncBatchManager.builder()
    .client(SqsAsyncClient.create())
    .scheduledExecutor(Executors.newScheduledThreadPool(5))
    .overrideConfiguration(b -> b
        .receiveMessageMinWaitDuration(Duration.ofSeconds(10))
        .receiveMessageVisibilityTimeout(Duration.ofSeconds(1))
        .receiveMessageAttributeNames(Collections.singletonList("*"))

    .receiveMessageSystemAttributeNames(Collections.singletonList(MessageSystemAttributeName.ALL))
    .build();
```

When you use this approach, you can adjust the settings on the `BatchOverrideConfiguration` object that are shown in the table in the [the section called “Configuration settings”](#) section. You can also provide a custom [`ScheduledExecutorService`](#) for the batch manager by using this approach.

Send messages

To send messages with the batch manager, use the [`SqsAsyncBatchManager#sendMessage`](#) method. The SDK buffers requests and sends them as a batch when the `maxBatchSize` or `sendRequestFrequency` values are reached.

The following example show a `sendMessage` request immediately following by another request. In this case, the SDK sends both messages in a single batch.

```
// Sending the first message
CompletableFuture<SendMessageResponse> futureOne =
    sqsAsyncBatchManager.sendMessage(r -> r.messageBody("One").queueUrl("queue"));

// Sending the second message
CompletableFuture<SendMessageResponse> futureTwo =
```

```
sqsAsyncBatchManager.sendMessage(r -> r.messageBody("Two").queueUrl("queue"));

// Waiting for both futures to complete and retrieving the responses
SendMessageResponse messageOne = futureOne.join();
SendMessageResponse messageTwo = futureTwo.join();
```

Change the message visibility timeout

You can change the visibility timeout of messages in a batch by using the [SqsAsyncBatchManager#changeMessageVisibility](#) method. The SDK buffers requests and sends them as a batch when the `maxBatchSize` or `sendRequestFrequency` values are reached.

The following example shows how to call the `changeMessageVisibility` method.

```
CompletableFuture<ChangeMessageVisibilityResponse> futureOne =
    sqsAsyncBatchManager.changeMessageVisibility(r ->
        r.receiptHandle("receiptHandle")
            .queueUrl("queue"));
ChangeMessageVisibilityResponse response = futureOne.join();
```

Delete messages

You can delete messages in a batch using the [SqsAsyncBatchManager#deleteMessage](#) method. The SDK buffers requests and sends them as a batch when the `maxBatchSize` or `sendRequestFrequency` values are reached.

The following example shows how you can call the `deleteMessage` method.

```
CompletableFuture<DeleteMessageResponse> futureOne =
    sqsAsyncBatchManager.deleteMessage(r ->
        r.receiptHandle("receiptHandle")
            .queueUrl("queue"));
DeleteMessageResponse response = futureOne.join();
```

Receive messages

Use default settings

When you poll the [SqsAsyncBatchManager#receiveMessage](#) method in your application, the batch manager fetches messages from its internal buffer, which the SDK automatically updates in the background.

The following example shows how to call the `receiveMessage` method.

```
CompletableFuture<ReceiveMessageResponse> responseFuture =
    sqsAsyncBatchManager.receiveMessage(r -> r.queueUrl("queueUrl"));
```

Use custom settings

If you want to customize the request further, for example by setting custom wait times and specifying the number of messages to retrieve, you can customize the request as shown in the following example.

```
CompletableFuture<ReceiveMessageResponse> response =
    sqsAsyncBatchManager.receiveMessage(r ->
        r.queueUrl("queueUrl")
            .waitTimeSeconds(5)
            .visibilityTimeout(20));
```

Note

If you call `receiveMessage` with a [ReceiveMessageRequest](#) that includes any of the following parameters, the SDK bypasses the batch manager and sends a regular asynchronous `receiveMessage` request:

- `messageAttributeNames`
- `messageSystemAttributeNames`
- `messageSystemAttributeNamesWithStrings`
- `overrideConfiguration`

Override configuration settings for `SqsAsyncBatchManager`

You can adjust the following settings when you create an `SqsAsyncBatchManager` instance. The following list of settings are available on the [BatchOverrideConfiguration.Builder](#).

Setting	Description	Default value
<code>maxBatchSize</code>	Maximum number of request per batch for each	10

Setting	Description	Default value
	SendMessageBatchRequest, ChangeMessageVisibilityBatchRequest, or DeleteMessageBatchRequest. The maximum value is 10.	
sendRequestFrequency	Time before sending a batch, unless maxBatchSize is reached earlier. Higher values may reduce requests but increase latency.	200ms
receiveMessageVisibilityTimeout	Visibility timeout for messages. If unset, the queue's default is used.	Queue's default
receiveMessageMinWaitDuration	Minimum wait time for receiveMessage requests. Avoid setting to 0 to prevent CPU waste.	50ms
receiveMessageSystemAttributeNames	List of system attribute names to request for receiveMessage calls.	None
receiveMessageAttributeNames	List of attribute names to request for receiveMessage calls.	None

Work with Amazon Simple Queue Service message queues

A *message queue* is the logical container used for sending messages reliably in Amazon Simple Queue Service. There are two types of queues: *standard* and *first-in, first-out (FIFO)*. To learn more about queues and the differences between these types, see the [Amazon Simple Queue Service Developer Guide](#).

This topic describes how to create, list, delete, and get the URL of an Amazon Simple Queue Service queue by using the AWS SDK for Java.

The `SqsClient` variable that is used in the following examples can be created from the following snippet.

```
SqsClient sqsClient = SqsClient.create();
```

When you create an `SqsClient` by using the static `create()` method, the SDK configures the Region by using the [default region provider chain](#) and the credentials by using the [default credentials provider chain](#).

Create a queue

Use the `SqsClient`'s `createQueue` method, and provide a [CreateQueueRequest](#) object that describes the queue parameters as shown in the following code snippet.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
        CreateQueueRequest createQueueRequest = CreateQueueRequest.builder()
            .queueName(queueName)
            .build();

        sqsClient.createQueue(createQueueRequest);
```

See the [complete sample](#) on GitHub.

List queues

To list the Amazon Simple Queue Service queues for your account, call the `SqsClient`'s `listQueues` method with a [ListQueuesRequest](#) object.

When you use the form of the [listQueues](#) method that takes no parameters, the service returns *all queues*—up to 1,000 queues.

You can supply a queue name prefix to the [ListQueuesRequest](#) object to limit the results to queues that match that prefix as shown in the following code.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
String prefix = "que";

try {
    ListQueuesRequest listQueuesRequest =
ListQueuesRequest.builder().queueNamePrefix(prefix).build();
    ListQueuesResponse listQueuesResponse =
sqsClient.listQueues(listQueuesRequest);

    for (String url : listQueuesResponse.queueUrls()) {
        System.out.println(url);
    }

} catch (SqsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
```

See the [complete sample](#) on GitHub.

Get the URL for a queue

The following code shows how to get the URL for a queue by calling the `SqsClient`'s `getQueueUrl` method with a [GetQueueUrlRequest](#) object.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
GetQueueUrlResponse getQueueUrlResponse =  
  
sqsClient.getQueueUrl(GetQueueUrlRequest.builder().queueName(queueName).build());  
String queueUrl = getQueueUrlResponse.queueUrl();  
return queueUrl;
```

See the [complete sample](#) on GitHub.

Delete a queue

Provide the queue's [URL](#) to the [DeleteQueueRequest](#) object. Then call the `SqsClient`'s `deleteQueue` method to delete a queue as shown in the following code.

Imports

```
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.sqs.SqsClient;  
import software.amazon.awssdk.services.sqs.model.*;  
import java.util.List;
```

Code

```
public static void deleteSQSQueue(SqsClient sqsClient, String queueName) {  
  
    try {  
  
        GetQueueUrlRequest getQueueRequest = GetQueueUrlRequest.builder()  
            .queueName(queueName)  
            .build();  
  
        String queueUrl = sqsClient.getQueueUrl(getQueueRequest).queueUrl();  
  
        DeleteQueueRequest deleteQueueRequest = DeleteQueueRequest.builder()  
            .queueUrl(queueUrl)  
            .build();  
  
        sqsClient.deleteQueue(deleteQueueRequest);  
  
    } catch (SqsException e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
    }  
}
```

```
        System.exit(1);
    }
}
```

See the [complete sample](#) on GitHub.

More information

- [DeleteQueue](#) in the Amazon Simple Queue Service API Reference

Send, receive, and delete Amazon Simple Queue Service messages

A message is a piece of data that can be sent and received by distributed components. Messages are always delivered using an [SQS Queue](#).

The `sqsClient` variable that is used in the following examples can be created from the following snippet.

```
SqsClient sqsClient = SqsClient.create();
```

When you create an `SqsClient` by using the static `create()` method, the SDK configures the Region by using the [default region provider chain](#) and the credentials by using the [default credentials provider chain](#).

Send a message

Add a single message to an Amazon Simple Queue Service queue by calling the `SqsClient` client `sendMessage` method. Provide a [SendMessageRequest](#) object that contains the queue's [URL](#), message body, and optional delay value (in seconds).

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
```

```
import java.util.List;
```

Code

```
sqsClient.sendMessage(SendMessageRequest.builder()
    .queueUrl(queueUrl)
    .messageBody("Hello world!")
    .delaySeconds(10)
    .build());

sqsClient.sendMessage(sendMsgRequest);
```

Send multiple messages in a request

Send more than one message in a single request by using the `SqsClient` `sendMessageBatch` method. This method takes a [SendMessageBatchRequest](#) that contains the queue URL and a list of messages to send. (Each message is a [SendMessageBatchRequestEntry](#).) You can also delay sending a specific message by setting a delay value on the message.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
SendMessageBatchRequest sendMessageBatchRequest =
SendMessageBatchRequest.builder()
    .queueUrl(queueUrl)

    .entries(SendMessageBatchRequestEntry.builder().id("id1").messageBody("Hello from msg
1").build(),

SendMessageBatchRequestEntry.builder().id("id2").messageBody("msg
2").delaySeconds(10).build())
    .build();
sqsClient.sendMessageBatch(sendMessageBatchRequest);
```

See the [complete sample](#) on GitHub.

Retrieve Messages

Retrieve any messages that are currently in the queue by calling the `SqsClient` `receiveMessage` method. This method takes a [ReceiveMessageRequest](#) that contains the queue URL. You can also specify the maximum number of messages to return. Messages are returned as a list of [Message](#) objects.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
try {
    ReceiveMessageRequest receiveMessageRequest =
ReceiveMessageRequest.builder()
        .queueUrl(queueUrl)
        .numberOfMessages(5)
        .build();
    List<Message> messages =
sqsClient.receiveMessage(receiveMessageRequest).messages();
    return messages;
} catch (SqsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return null;
```

See the [complete sample](#) on GitHub.

Delete a message after receipt

After receiving a message and processing its contents, delete the message from the queue by sending the message's receipt handle and queue URL to the `SqsClient`'s [deleteMessage](#) method.

Imports

```
import software.amazon.awssdk.regions.Region;
```

```
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```
try {
    for (Message message : messages) {
        DeleteMessageRequest deleteMessageRequest =
DeleteMessageRequest.builder()
                        .queueUrl(queueUrl)
                        .receiptHandle(message.receiptHandle())
                        .build();
        sqsClient.deleteMessage(deleteMessageRequest);
    }
}
```

See the [complete sample](#) on GitHub.

Work with Amazon Transcribe

The following example shows how bidirectional streaming works using Amazon Transcribe. Bidirectional streaming implies that there's both a stream of data going to the service and being received back in real time. The example uses Amazon Transcribe streaming transcription to send an audio stream and receive a stream of transcribed text back in real time.

See [Streaming Transcription](#) in the Amazon Transcribe Developer Guide to learn more about this feature.

See [Getting Started](#) in the Amazon Transcribe Developer Guide to get started using Amazon Transcribe.

Set up the microphone

This code uses the `javax.sound.sampled` package to stream audio from an input device.

Code

```
import javax.sound.sampled.AudioFormat;
import javax.sound.sampled.AudioSystem;
import javax.sound.sampled.DataLine;
import javax.sound.sampled.TargetDataLine;

public class Microphone {

    public static TargetDataLine get() throws Exception {
        AudioFormat format = new AudioFormat(16000, 16, 1, true, false);
        DataLine.Info datalineInfo = new DataLine.Info(TargetDataLine.class, format);

        TargetDataLine dataLine = (TargetDataLine) AudioSystem.getLine(datalineInfo);
        dataLine.open(format);

        return dataLine;
    }
}
```

See the [complete example](#) on GitHub.

Create a publisher

This code implements a publisher that publishes audio data from the Amazon Transcribe audio stream.

Code

```
package com.amazonaws.transcribe;

import java.io.IOException;
import java.io.InputStream;
import java.io.UncheckedIOException;
import java.nio.ByteBuffer;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.atomic.AtomicLong;
import org.reactivestreams.Publisher;
```

```
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.services.transcribestreaming.model.AudioEvent;
import software.amazon.awssdk.services.transcribestreaming.model.AudioStream;
import
    software.amazon.awssdk.services.transcribestreaming.model.TranscribeStreamingException;

public class AudioStreamPublisher implements Publisher<AudioStream> {
    private final InputStream inputStream;

    public AudioStreamPublisher(InputStream inputStream) {
        this.inputStream = inputStream;
    }

    @Override
    public void subscribe(Subscriber<? super AudioStream> s) {
        s.onSubscribe(new SubscriptionImpl(s, inputStream));
    }

    private class SubscriptionImpl implements Subscription {
        private static final int CHUNK_SIZE_IN_BYTES = 1024 * 1;
        private ExecutorService executor = Executors.newFixedThreadPool(1);
        private AtomicLong demand = new AtomicLong(0);

        private final Subscriber<? super AudioStream> subscriber;
        private final InputStream inputStream;

        private SubscriptionImpl(Subscriber<? super AudioStream> s, InputStream
inputStream) {
            this.subscriber = s;
            this.inputStream = inputStream;
        }

        @Override
        public void request(long n) {
            if (n <= 0) {
                subscriber.onError(new IllegalArgumentException("Demand must be
positive"));
            }

            demand.getAndAdd(n);
        }
    }
}
```

```

        executor.submit(() -> {
            try {
                do {
                    ByteBuffer audioBuffer = getNextEvent();
                    if (audioBuffer.remaining() > 0) {
                        AudioEvent audioEvent = audioEventFromBuffer(audioBuffer);
                        subscriber.onNext(audioEvent);
                    } else {
                        subscriber.onComplete();
                        break;
                    }
                } while (demand.decrementAndGet() > 0);
            } catch (TranscribeStreamingException e) {
                subscriber.onError(e);
            }
        });
    }

    @Override
    public void cancel() {

    }

    private ByteBuffer getNextEvent() {
        ByteBuffer audioBuffer;
        byte[] audioBytes = new byte[CHUNK_SIZE_IN_BYTES];

        int len = 0;
        try {
            len = inputStream.read(audioBytes);

            if (len <= 0) {
                audioBuffer = ByteBuffer.allocate(0);
            } else {
                audioBuffer = ByteBuffer.wrap(audioBytes, 0, len);
            }
        } catch (IOException e) {
            throw new UncheckedIOException(e);
        }

        return audioBuffer;
    }

    private AudioEvent audioEventFromBuffer(ByteBuffer bb) {

```

```
        return AudioEvent.builder()
            .audioChunk(SdkBytes.fromByteBuffer(bb))
            .build();
    }
}
```

See the [complete example](#) on GitHub.

Create the client and start the stream

In the main method, create a request object, start the audio input stream and instantiate the publisher with the audio input.

You must also create a [StartStreamTranscriptionResponseHandler](#) to specify how to handle the response from Amazon Transcribe.

Then, use the `TranscribeStreamingAsyncClient`'s `startStreamTranscription` method to start the bidirectional streaming.

Imports

```
import javax.sound.sampled.AudioFormat;
import javax.sound.sampled.AudioSystem;
import javax.sound.sampled.DataLine;
import javax.sound.sampled.TargetDataLine;
import javax.sound.sampled.AudioInputStream;
import software.amazon.awssdk.regions.Region;
import
    software.amazon.awssdk.services.transcribestreaming.TranscribeStreamingAsyncClient;
import
    software.amazon.awssdk.services.transcribestreaming.model.TranscribeStreamingException ;
import
    software.amazon.awssdk.services.transcribestreaming.model.StartStreamTranscriptionRequest;
import software.amazon.awssdk.services.transcribestreaming.model.MediaEncoding;
import software.amazon.awssdk.services.transcribestreaming.model.LanguageCode;
import
    software.amazon.awssdk.services.transcribestreaming.model.StartStreamTranscriptionResponseHandler;

SDK for Java 2.x code examples

The code examples in this topic show you how to use the AWS SDK for Java 2.x with AWS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Some services contain additional example categories that show how to leverage libraries or functions specific to the service.

ACM examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with ACM.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Actions

AddTagsToCertificate

The following code example shows how to use AddTagsToCertificate.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 * <p>
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class AddTagsToCertificate {
```

```

public static void main(String[] args) {
    final String usage = ""

        Usage:    <certArn>

        Where:
            certArn - the ARN of the certificate.
        "";
    if (args.length != 1) {
        System.out.println(usage);
        return;
    }

    String certArn = args[0];
    addTags(certArn);
}

/**
 * Adds tags to a certificate in AWS Certificate Manager (ACM).
 *
 * @param certArn the Amazon Resource Name (ARN) of the certificate to add tags
to
 */
public static void addTags(String certArn) {
    AcmClient acmClient = AcmClient.create();
    List<Tag> expectedTags =
List.of(Tag.builder().key("key").value("value").build());
    AddTagsToCertificateRequest addTagsToCertificateRequest =
AddTagsToCertificateRequest.builder()
        .certificateArn(certArn)
        .tags(expectedTags)
        .build();

    try {
        acmClient.addTagsToCertificate(addTagsToCertificateRequest);
        System.out.println("Successfully added tags to a certificate");
    } catch (AcmException e) {
        System.out.println(e.getMessage());
    }
}
}

```

API Gateway examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with API Gateway.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Actions

CreateDeployment

The following code example shows how to use CreateDeployment.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static String createNewDeployment(ApiGatewayClient apiGateway, String
restApiId, String stageName) {

    try {
        CreateDeploymentRequest request = CreateDeploymentRequest.builder()
            .restApiId(restApiId)
            .description("Created using the AWS API Gateway Java API")
            .stageName(stageName)
            .build();

        CreateDeploymentResponse response =
apiGateway.createDeployment(request);
        System.out.println("The id of the deployment is " + response.id());
        return response.id();

    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateDeployment](#) in *AWS SDK for Java 2.x API Reference*.

CreateRestApi

The following code example shows how to use `CreateRestApi`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static String createAPI(ApiGatewayClient apiGateway, String restApiId,
String restApiName) {

    try {
        CreateRestApiRequest request = CreateRestApiRequest.builder()
            .cloneFrom(restApiId)
            .description("Created using the Gateway Java API")
            .name(restApiName)
            .build();

        CreateRestApiResponse response = apiGateway.createRestApi(request);
        System.out.println("The id of the new api is " + response.id());
        return response.id();

    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateRestApi](#) in *AWS SDK for Java 2.x API Reference*.

DeleteDeployment

The following code example shows how to use `DeleteDeployment`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void deleteSpecificDeployment(ApiGatewayClient apiGateway, String
restApiId, String deploymentId) {

    try {
        DeleteDeploymentRequest request = DeleteDeploymentRequest.builder()
            .restApiId(restApiId)
            .deploymentId(deploymentId)
            .build();

        apiGateway.deleteDeployment(request);
        System.out.println("Deployment was deleted");

    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteDeployment](#) in *AWS SDK for Java 2.x API Reference*.

DeleteRestApi

The following code example shows how to use DeleteRestApi.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void deleteAPI(ApiGatewayClient apiGateway, String restApiId) {  
  
    try {  
        DeleteRestApiRequest request = DeleteRestApiRequest.builder()  
            .restApiId(restApiId)  
            .build();  
  
        apiGateway.deleteRestApi(request);  
        System.out.println("The API was successfully deleted");  
  
    } catch (ApiGatewayException e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

- For API details, see [DeleteRestApi](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Create a serverless application to manage photos

The following code example shows how to create a serverless application that lets users manage photos using labels.

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda

- Amazon Rekognition
- Amazon S3
- Amazon SNS

Use API Gateway to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by Amazon API Gateway.

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

AWS community contributions

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Application Auto Scaling examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Application Auto Scaling.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

UpdateRoutingControlState

The following code example shows how to use `UpdateRoutingControlState`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

    public static UpdateRoutingControlStateResponse
updateRoutingControlState(List<ClusterEndpoint> clusterEndpoints,
        String routingControlArn,
        String routingControlState) {
    // As a best practice, we recommend choosing a random cluster endpoint to
get or
    // set routing control states.
    // For more information, see
    // https://docs.aws.amazon.com/r53recovery/latest/dg/route53-arc-best-
practices.html#route53-arc-best-practices.regional
    Collections.shuffle(clusterEndpoints);
    for (ClusterEndpoint clusterEndpoint : clusterEndpoints) {
        try {
            System.out.println(clusterEndpoint);
            Route53RecoveryClusterClient client =
Route53RecoveryClusterClient.builder()
                .endpointOverride(URI.create(clusterEndpoint.endpoint()))
                .region(Region.of(clusterEndpoint.region()))
                .build();
            return client.updateRoutingControlState(
                UpdateRoutingControlStateRequest.builder()

.routingControlArn(routingControlArn).routingControlState(routingControlState).build());
        } catch (Exception exception) {

```

```
        System.out.println(exception);
    }
}
return null;
}
```

- For API details, see [UpdateRoutingControlState](#) in *AWS SDK for Java 2.x API Reference*.

Aurora examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Aurora.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
```

```
import software.amazon.awssdk.services.rds.paginators.DescribeDBClustersIterable;

public class DescribeDbClusters {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        RdsClient rdsClient = RdsClient.builder()
            .region(region)
            .build();

        describeClusters(rdsClient);
        rdsClient.close();
    }

    public static void describeClusters(RdsClient rdsClient) {
        DescribeDBClustersIterable clustersIterable =
rdsClient.describeDBClustersPaginator();
        clustersIterable.stream()
            .flatMap(r -> r.dbClusters().stream())
            .forEach(cluster -> System.out
                .println("Database name: " + cluster.databaseName() + " Arn
= " + cluster.dbClusterArn()));
    }
}
```

- For API details, see [DescribeDBClusters](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)
- [Scenarios](#)

Basics

Learn the basics

The following code example shows how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.

- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
 * services-use-secrets_RS.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
 * by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
 * 2. Selects an engine family and creates a custom DB cluster parameter group
 * by invoking the describeDBClusterParameters method.
 * 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
 * method.
 * 4. Gets parameters in the group by invoking the describeDBClusterParameters
 * method.
 * 5. Modifies the auto_increment_offset parameter by invoking the
 * modifyDbClusterParameterGroupRequest method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the
 * describeDbEngineVersions method.
```

```

* 8. Creates an Aurora DB cluster database cluster that contains a MySQL
* database.
* 9. Waits for DB instance to be ready.
* 10. Gets a list of instance classes available for the selected engine.
* 11. Creates a database instance in the cluster.
* 12. Waits for DB instance to be ready.
* 13. Creates a snapshot.
* 14. Waits for DB snapshot to be ready.
* 15. Deletes the DB cluster.
* 16. Deletes the DB cluster group.
*/

Actions

CreateDBCluster

The following code example shows how to use `CreateDBCluster`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static String createDBCluster(RdsClient rdsClient, String
dbParameterGroupFamily, String dbName,
    String dbClusterIdentifier, String userName, String password) {
    try {
        CreateDbClusterRequest clusterRequest = CreateDbClusterRequest.builder()
            .databaseName(dbName)
            .dbClusterIdentifier(dbClusterIdentifier)
            .dbClusterParameterGroupName(dbParameterGroupFamily)
            .engine("aurora-mysql")
            .masterUsername(userName)
            .masterUserPassword(password)
            .build();

        CreateDbClusterResponse response =
rdsClient.createDBCluster(clusterRequest);
        return response.dbCluster().dbClusterArn();

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateDBCluster](#) in *AWS SDK for Java 2.x API Reference*.

CreateDBClusterParameterGroup

The following code example shows how to use `CreateDBClusterParameterGroup`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void createDBClusterParameterGroup(RdsClient rdsClient, String
dbClusterGroupName,
```

```
String dbParameterGroupFamily) {
    try {
        CreateDbClusterParameterGroupRequest groupRequest =
        CreateDbClusterParameterGroupRequest.builder()
            .dbClusterParameterGroupName(dbClusterGroupName)
            .dbParameterGroupFamily(dbParameterGroupFamily)
            .description("Created by using the AWS SDK for Java")
            .build();

        CreateDbClusterParameterGroupResponse response =
        rdsClient.createDBClusterParameterGroup(groupRequest);
        System.out.println("The group name is " +
        response.dbClusterParameterGroup().dbClusterParameterGroupName());

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [CreateDBClusterParameterGroup](#) in *AWS SDK for Java 2.x API Reference*.

CreateDBClusterSnapshot

The following code example shows how to use `CreateDBClusterSnapshot`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void createDBClusterSnapshot(RdsClient rdsClient, String
dbInstanceClusterIdentifier,
    String dbSnapshotIdentifier) {
    try {
        CreateDbClusterSnapshotRequest snapshotRequest =
        CreateDbClusterSnapshotRequest.builder()
            .dbClusterIdentifier(dbInstanceClusterIdentifier)
```

```
        .dbClusterSnapshotIdentifier(dbSnapshotIdentifier)
        .build();

        CreateDbClusterSnapshotResponse response =
rdsClient.createDBClusterSnapshot(snapshotRequest);
        System.out.println("The Snapshot ARN is " +
response.dbClusterSnapshot().dbClusterSnapshotArn());

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [CreateDBClusterSnapshot](#) in *AWS SDK for Java 2.x API Reference*.

CreateDBInstance

The following code example shows how to use CreateDBInstance.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static String createDBInstanceCluster(RdsClient rdsClient,
        String dbInstanceIdentifier,
        String dbInstanceClusterIdentifier,
        String instanceClass) {
    try {
        CreateDbInstanceRequest instanceRequest =
CreateDbInstanceRequest.builder()
            .dbInstanceIdentifier(dbInstanceIdentifier)
            .dbClusterIdentifier(dbInstanceClusterIdentifier)
            .engine("aurora-mysql")
            .dbInstanceClass(instanceClass)
            .build();
```

```
        CreateDbInstanceResponse response =
rdsClient.createDBInstance(instanceRequest);
        System.out.print("The status is " +
response.dbInstance().dbInstanceStatus());
        return response.dbInstance().dbInstanceArn();

    } catch (RdsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateDBInstance](#) in *AWS SDK for Java 2.x API Reference*.

DeleteDBCluster

The following code example shows how to use DeleteDBCluster.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void deleteCluster(RdsClient rdsClient, String
dbInstanceClusterIdentifier) {
    try {
        DeleteDbClusterRequest deleteDbClusterRequest =
DeleteDbClusterRequest.builder()
            .dbClusterIdentifier(dbInstanceClusterIdentifier)
            .skipFinalSnapshot(true)
            .build();

        rdsClient.deleteDBCluster(deleteDbClusterRequest);
        System.out.println(dbInstanceClusterIdentifier + " was deleted!");

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
    }
}
```

```
        System.exit(1);
    }
}
```

- For API details, see [DeleteDBCluster](#) in *AWS SDK for Java 2.x API Reference*.

DeleteDBClusterParameterGroup

The following code example shows how to use `DeleteDBClusterParameterGroup`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void deleteDBClusterGroup(RdsClient rdsClient, String
dbClusterGroupName, String clusterDBARN)
    throws InterruptedException {
    try {
        boolean isDataDel = false;
        boolean didFind;
        String instanceARN;

        // Make sure that the database has been deleted.
        while (!isDataDel) {
            DescribeDbInstancesResponse response =
rdsClient.describeDBInstances();
            List<DBInstance> instanceList = response.dbInstances();
            int listSize = instanceList.size();
            didFind = false;
            int index = 1;
            for (DBInstance instance : instanceList) {
                instanceARN = instance.dbInstanceArn();
                if (instanceARN.compareTo(clusterDBARN) == 0) {
                    System.out.println(clusterDBARN + " still exists");
                    didFind = true;
                }
            }
            if ((index == listSize) && (!didFind)) {
```

```

        // Went through the entire list and did not find the
database ARN.
        isDataDel = true;
    }
    Thread.sleep(sleepTime * 1000);
    index++;
}
}

DeleteDbClusterParameterGroupRequest clusterParameterGroupRequest =
DeleteDbClusterParameterGroupRequest
    .builder()
    .dbClusterParameterGroupName(dbClusterGroupName)
    .build();

rdsClient.deleteDBClusterParameterGroup(clusterParameterGroupRequest);
System.out.println(dbClusterGroupName + " was deleted.");

} catch (RdsException e) {
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
}
}

```

- For API details, see [DeleteDBClusterParameterGroup](#) in *AWS SDK for Java 2.x API Reference*.

DeleteDBInstance

The following code example shows how to use DeleteDBInstance.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

public static void deleteDatabaseInstance(RdsClient rdsClient, String
dbInstanceIdentifier) {
    try {

```

```
        DeleteDbInstanceRequest deleteDbInstanceRequest =
DeleteDbInstanceRequest.builder()
        .dbInstanceIdentifier(dbInstanceIdentifier)
        .deleteAutomatedBackups(true)
        .skipFinalSnapshot(true)
        .build();

        DeleteDbInstanceResponse response =
rdsClient.deleteDBInstance(deleteDbInstanceRequest);
        System.out.println("The status of the database is " +
response.dbInstance().dbInstanceStatus());

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteDBInstance](#) in *AWS SDK for Java 2.x API Reference*.

DescribeDBClusterParameterGroups

The following code example shows how to use `DescribeDBClusterParameterGroups`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

DescribeDBEngineVersions

The following code example shows how to use DescribeDBEngineVersions.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

public static void describeDBEngines(RdsClient rdsClient) {
    try {
        DescribeDbEngineVersionsRequest engineVersionsRequest =
DescribeDbEngineVersionsRequest.builder()
            .engine("aurora-mysql")

```

```

        .defaultOnly(true)
        .maxRecords(20)
        .build();

    DescribeDbEngineVersionsResponse response =
rdsClient.describeDBEngineVersions(engineVersionsRequest);
    List<DBEngineVersion> engines = response.dbEngineVersions();

    // Get all DBEngineVersion objects.
    for (DBEngineVersion engineOb : engines) {
        System.out.println("The name of the DB parameter group family for
the database engine is "
            + engineOb.dbParameterGroupFamily());
        System.out.println("The name of the database engine " +
engineOb.engine());
        System.out.println("The version number of the database engine " +
engineOb.engineVersion());
    }

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}

```

ModifyDBClusterParameterGroup

The following code example shows how to use `ModifyDBClusterParameterGroup`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void describeDbClusterParameterGroups(RdsClient rdsClient, String
dbClusterGroupName) {
    try {
        DescribeDbClusterParameterGroupsRequest groupsRequest =
DescribeDbClusterParameterGroupsRequest.builder()
            .dbClusterParameterGroupName(dbClusterGroupName)
            .maxRecords(20)
            .build();

        List<DBClusterParameterGroup> groups =
rdsClient.describeDBClusterParameterGroups(groupsRequest)
            .dbClusterParameterGroups();
        for (DBClusterParameterGroup group : groups) {
            System.out.println("The group name is " +
group.dbClusterParameterGroupName());
            System.out.println("The group ARN is " +
group.dbClusterParameterGroupArn());
        }

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [ModifyDBClusterParameterGroup](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Create an Aurora Serverless work item tracker

The following code example shows how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Auto Scaling examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Auto Scaling.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Auto Scaling

The following code examples show how to get started using Auto Scaling.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.autoscaling.AutoScalingClient;
import software.amazon.awssdk.services.autoscaling.model.AutoScalingGroup;
import
    software.amazon.awssdk.services.autoscaling.model.DescribeAutoScalingGroupsResponse;
import java.util.List;

/**
 * Before running this SDK for Java (v2) code example, set up your development
 * environment, including your credentials.
 *

 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeAutoScalingGroups {
    public static void main(String[] args) throws InterruptedException {
        AutoScalingClient autoScalingClient = AutoScalingClient.builder()
            .region(Region.US_EAST_1)
            .build();

        describeGroups(autoScalingClient);
    }

    public static void describeGroups(AutoScalingClient autoScalingClient) {
```

```
DescribeAutoScalingGroupsResponse response =
autoScalingClient.describeAutoScalingGroups();
List<AutoScalingGroup> groups = response.autoScalingGroups();
groups.forEach(group -> {
    System.out.println("Group Name: " + group.autoScalingGroupName());
    System.out.println("Group ARN: " + group.autoScalingGroupARN());
});
}
```

- For API details, see [DescribeAutoScalingGroups](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)
- [Scenarios](#)

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon EC2 Auto Scaling group with a launch template and Availability Zones, and get information about running instances.
- Enable Amazon CloudWatch metrics collection.
- Update the group's desired capacity and wait for an instance to start.
- Terminate an instance in the group.
- List scaling activities that occur in response to user requests and capacity changes.
- Get statistics for CloudWatch metrics, then clean up resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this SDK for Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * In addition, create a launch template. For more information, see the
 * following topic:
 *
 * https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ec2-launch-
templates.html#create-launch-template
 *
 * This code example performs the following operations:
 * 1. Creates an Auto Scaling group using an AutoScalingWaiter.
 * 2. Gets a specific Auto Scaling group and returns an instance Id value.
 * 3. Describes Auto Scaling with the Id value.
 * 4. Enables metrics collection.
 * 5. Update an Auto Scaling group.
 * 6. Describes Account details.
 * 7. Describe account details"
 * 8. Updates an Auto Scaling group to use an additional instance.
 * 9. Gets the specific Auto Scaling group and gets the number of instances.
 * 10. List the scaling activities that have occurred for the group.
 * 11. Terminates an instance in the Auto Scaling group.
 * 12. Stops the metrics collection.
 * 13. Deletes the Auto Scaling group.
 */

SetDesiredCapacityRequest.builder()
            .autoScalingGroupName(groupName)
            .desiredCapacity(2)
            .build();

        autoScalingClient.setDesiredCapacity(capacityRequest);
        System.out.println("You have set the DesiredCapacity to 2");

    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [SetDesiredCapacity](#) in *AWS SDK for Java 2.x API Reference*.

TerminateInstanceInAutoScalingGroup

The following code example shows how to use TerminateInstanceInAutoScalingGroup.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void terminateInstanceInAutoScalingGroup(AutoScalingClient
autoScalingClient, String instanceId) {
    try {
        TerminateInstanceInAutoScalingGroupRequest request =
        TerminateInstanceInAutoScalingGroupRequest.builder()
            .instanceId(instanceId)
            .shouldDecrementDesiredCapacity(false)
            .build();

        autoScalingClient.terminateInstanceInAutoScalingGroup(request);
        System.out.println("You have terminated instance " + instanceId);

    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [TerminateInstanceInAutoScalingGroup](#) in *AWS SDK for Java 2.x API Reference*.

UpdateAutoScalingGroup

The following code example shows how to use `UpdateAutoScalingGroup`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void updateAutoScalingGroup(AutoScalingClient autoScalingClient,
String groupName,
    String launchTemplateName) {
    try {
        AutoScalingWaiter waiter = autoScalingClient.waiter();
        LaunchTemplateSpecification templateSpecification =
LaunchTemplateSpecification.builder()
            .launchTemplateName(launchTemplateName)
            .build();

        UpdateAutoScalingGroupRequest groupRequest =
UpdateAutoScalingGroupRequest.builder()
            .maxSize(3)
            .autoScalingGroupName(groupName)
            .launchTemplate(templateSpecification)
            .build();

        autoScalingClient.updateAutoScalingGroup(groupRequest);
        DescribeAutoScalingGroupsRequest groupsRequest =
DescribeAutoScalingGroupsRequest.builder()
            .autoScalingGroupNames(groupName)
            .build();

        WaiterResponse<DescribeAutoScalingGroupsResponse> waiterResponse =
waiter
            .waitUntilGroupInService(groupsRequest);
        waiterResponse.matched().response().ifPresent(System.out::println);
        System.out.println("You successfully updated the auto scaling group " +
groupName);

    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [UpdateAutoScalingGroup](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run the interactive scenario at a command prompt.

```

AWS Batch examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS Batch.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS Batch

The following code example shows how to get started using AWS Batch.

SDK for Java 2.x

Note

Scenarios

Learn AWS Batch core operations

The following code example shows how to:

- Create an AWS Batch compute environment.
- Check the status of the compute environment.
- Set up an AWS Batch job queue and job definition.
- Register a job definition.
- Submit an AWS Batch Job.
- Get a list of jobs applicable to the job queue.
- Check the status of job.
- Delete AWS Batch resources.

Amazon Bedrock examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Bedrock.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Amazon Bedrock Runtime examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Bedrock Runtime.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- [Scenarios](#)
- [AI21 Labs Jurassic-2](#)
- [Amazon Titan Image Generator](#)
- [Amazon Titan Text](#)
- [Amazon Titan Text Embeddings](#)
- [Anthropic Claude](#)
- [Cohere Command](#)
- [Meta Llama](#)
- [Mistral AI](#)
- [Stable Diffusion](#)

Scenarios

Create a playground application to interact with Amazon Bedrock foundation models

The following code example shows how to create playgrounds to interact with Amazon Bedrock foundation models through different modalities.

SDK for Java 2.x

The Java Foundation Model (FM) Playground is a Spring Boot sample application that showcases how to use Amazon Bedrock with Java. This example shows how Java developers can use Amazon Bedrock to build generative AI-enabled applications. You can test and interact with Amazon Bedrock foundation models by using the following three playgrounds:

- A text playground.

- A chat playground.
- An image playground.

The example also lists and displays the foundation models you have access to, along with their characteristics. For source code and deployment instructions, see the project in [GitHub](#).

Services used in this example

- Amazon Bedrock Runtime

AI21 Labs Jurassic-2

Converse

The following code example shows how to send a text message to AI21 Labs Jurassic-2, using Bedrock's Converse API.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Send a text message to AI21 Labs Jurassic-2, using Bedrock's Converse API.

```
// Use the Converse API to send a text message to AI21 Labs Jurassic-2.

import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider;
import software.amazon.awssdk.core.exception.SdkClientException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.bedrockruntime.BedrockRuntimeClient;
import software.amazon.awssdk.services.bedrockruntime.model.ContentBlock;
import software.amazon.awssdk.services.bedrockruntime.model.ConversationRole;
import software.amazon.awssdk.services.bedrockruntime.model.ConverseResponse;
import software.amazon.awssdk.services.bedrockruntime.model.Message;

public class Converse {

    public static String converse() {
```

```
// Create a Bedrock Runtime client in the AWS Region you want to use.
// Replace the DefaultCredentialsProvider with your preferred credentials
provider.
var client = BedrockRuntimeClient.builder()
    .credentialsProvider(DefaultCredentialsProvider.create())
    .region(Region.US_EAST_1)
    .build();

// Set the model ID, e.g., Jurassic-2 Mid.
var modelId = "ai21.j2-mid-v1";

// Create the input text and embed it in a message object with the user
role.
var inputText = "Describe the purpose of a 'hello world' program in one
line.";
var message = Message.builder()
    .content(ContentBlock.fromText(inputText))
    .role(ConversationRole.USER)
    .build();

try {
    // Send the message with a basic inference configuration.
    ConverseResponse response = client.converse(request -> request
        .modelId(modelId)
        .messages(message)
        .inferenceConfig(config -> config
            .maxTokens(512)
            .temperature(0.5F)
            .topP(0.9F)));

    // Retrieve the generated text from Bedrock's response object.
    var responseText = response.output().message().content().get(0).text();
    System.out.println(responseText);

    return responseText;

} catch (SdkClientException e) {

CloudFront examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudFront.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

            .build();

        CreateFunctionRequest functionRequest = CreateFunctionRequest.builder()
            .name(functionName)
            .functionCode(functionCode)
            .functionConfig(config)
            .build();

        CreateFunctionResponse response =
cloudFrontClient.createFunction(functionRequest);
        return response.functionSummary().functionMetadata().functionARN();

    } catch (CloudFrontException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
}
```

- For API details, see [CreateFunction](#) in *AWS SDK for Java 2.x API Reference*.

CreateKeyGroup

The following code example shows how to use CreateKeyGroup.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

A key group requires at least one public key that is used to verify signed URLs or cookies.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;

import java.util.UUID;

public class CreateKeyGroup {
    private static final Logger logger =
        LoggerFactory.getLogger(CreateKeyGroup.class);

    public static String createKeyGroup(CloudFrontClient cloudFrontClient, String
publicKeyId) {
        String keyGroupId = cloudFrontClient.createKeyGroup(b -> b.keyGroupConfig(c
-> c
            .items(publicKeyId)
            .name("JavaKeyGroup" + UUID.randomUUID()))
            .keyGroup().id());
        logger.info("KeyGroup created with ID: [{}]", keyGroupId);
        return keyGroupId;
    }
}
```

- For API details, see [CreateKeyGroup](#) in *AWS SDK for Java 2.x API Reference*.

CreatePublicKey

The following code example shows how to use CreatePublicKey.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

The following code example reads in a public key and uploads it to Amazon CloudFront.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.CreatePublicKeyResponse;
import software.amazon.awssdk.utils.IoUtils;

import java.io.IOException;
import java.io.InputStream;
import java.util.UUID;

public class CreatePublicKey {
    private static final Logger logger =
        LoggerFactory.getLogger(CreatePublicKey.class);

    public static String createPublicKey(CloudFrontClient cloudFrontClient, String
        publicKeyFileName) {
        try (InputStream is =
            CreatePublicKey.class.getClassLoader().getResourceAsStream(publicKeyFileName)) {
            String publicKeyString = IoUtils.toUtf8String(is);
            CreatePublicKeyResponse createPublicKeyResponse = cloudFrontClient
                .createPublicKey(b -> b.publicKeyConfig(c -> c
                    .name("JavaCreatedPublicKey" + UUID.randomUUID())
                    .encodedKey(publicKeyString)
                    .callerReference(UUID.randomUUID().toString())));
            String createdPublicKeyId = createPublicKeyResponse.publicKey().id();
            logger.info("Public key created with id: [{}]", createdPublicKeyId);
            return createdPublicKeyId;
        } catch (IOException e) {
```

```
        throw new RuntimeException(e);
    }
}
}
```

- For API details, see [CreatePublicKey](#) in *AWS SDK for Java 2.x API Reference*.

DeleteDistribution

The following code example shows how to use DeleteDistribution.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

The following code example updates a distribution to *disabled*, uses a waiter that waits for the change to be deployed, then deletes the distribution.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.internal.waiters.ResponseOrException;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.DeleteDistributionResponse;
import software.amazon.awssdk.services.cloudfront.model.DistributionConfig;
import software.amazon.awssdk.services.cloudfront.model.GetDistributionResponse;
import software.amazon.awssdk.services.cloudfront.waiters.CloudFrontWaiter;

public class DeleteDistribution {
    private static final Logger logger =
        LoggerFactory.getLogger(DeleteDistribution.class);

    public static void deleteDistribution(final CloudFrontClient
        cloudFrontClient, final String distributionId) {
        // First, disable the distribution by updating it.
        GetDistributionResponse response =
        cloudFrontClient.getDistribution(b -> b
            .id(distributionId));
```

```

        String etag = response.eTag();
        DistributionConfig distConfig =
response.distribution().distributionConfig();

        cloudFrontClient.updateDistribution(builder -> builder
            .id(distributionId)
            .distributionConfig(builder1 -> builder1

.cacheBehaviors(distConfig.cacheBehaviors())

.defaultCacheBehavior(distConfig.defaultCacheBehavior())
            .enabled(false)
            .origins(distConfig.origins())
            .comment(distConfig.comment())

.callerReference(distConfig.callerReference())

.defaultCacheBehavior(distConfig.defaultCacheBehavior())
            .priceClass(distConfig.priceClass())
            .aliases(distConfig.aliases())
            .logging(distConfig.logging())

.defaultRootObject(distConfig.defaultRootObject())

.customErrorResponses(distConfig.customErrorResponses())

.httpVersion(distConfig.httpVersion())

.isIPV6Enabled(distConfig.isIPV6Enabled())

.restrictions(distConfig.restrictions())

.viewerCertificate(distConfig.viewerCertificate())
            .webACLId(distConfig.webACLId())

.originGroups(distConfig.originGroups())
            .ifMatch(etag));

        logger.info("Distribution [{}] is DISABLED, waiting for deployment
before deleting ...",
            distributionId);
        GetDistributionResponse distributionResponse;
        try (CloudFrontWaiter cfWaiter =
CloudFrontWaiter.builder().client(cloudFrontClient).build()) {

```

```

        ResponseOrException<GetDistributionResponse>
responseOrException = cfWaiter
                                .waitUntilDistributionDeployed(builder ->
builder.id(distributionId)).matched();
        distributionResponse = responseOrException.response()
                                .orElseThrow(() -> new
RuntimeException("Could not disable distribution"));
    }

    DeleteDistributionResponse deleteDistributionResponse =
cloudFrontClient
                                .deleteDistribution(builder -> builder
                                .id(distributionId)

.ifMatch(distributionResponse.eTag()));
    if (deleteDistributionResponse.sdkHttpResponse().isSuccessful()) {
        logger.info("Distribution [{}] DELETED", distributionId);
    }
}
}
}

```

Scenarios

Delete signing resources

The following code example shows how to delete resources that are used to gain access to restricted content in an Amazon Simple Storage Service (Amazon S3) bucket.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.DeleteKeyGroupResponse;
import
    software.amazon.awssdk.services.cloudfront.model.DeleteOriginAccessControlResponse;
import software.amazon.awssdk.services.cloudfront.model.DeletePublicKeyResponse;
import software.amazon.awssdk.services.cloudfront.model.GetKeyGroupResponse;
import
    software.amazon.awssdk.services.cloudfront.model.GetOriginAccessControlResponse;
import software.amazon.awssdk.services.cloudfront.model.GetPublicKeyResponse;

public class DeleteSigningResources {
    private static final Logger logger =
        LoggerFactory.getLogger(DeleteSigningResources.class);

    public static void deleteOriginAccessControl(final CloudFrontClient
        cloudFrontClient,
        final String originAccessControlId) {
        GetOriginAccessControlResponse getResponse = cloudFrontClient
            .getOriginAccessControl(b -> b.id(originAccessControlId));
        DeleteOriginAccessControlResponse deleteResponse =
            cloudFrontClient.deleteOriginAccessControl(builder -> builder
                .id(originAccessControlId)
```

```

        .ifMatch(getResponse.eTag()));
    if (deleteResponse.sdkHttpResponse().isSuccessful()) {
        logger.info("Successfully deleted Origin Access Control [{}]",
originAccessControlId);
    }
}

public static void deleteKeyGroup(final CloudFrontClient cloudFrontClient, final
String keyGroupId) {

    GetKeyGroupResponse getResponse = cloudFrontClient.getKeyGroup(b ->
b.id(keyGroupId));
    DeleteKeyGroupResponse deleteResponse =
cloudFrontClient.deleteKeyGroup(builder -> builder
        .id(keyGroupId)
        .ifMatch(getResponse.eTag()));
    if (deleteResponse.sdkHttpResponse().isSuccessful()) {
        logger.info("Successfully deleted Key Group [{}]", keyGroupId);
    }
}

public static void deletePublicKey(final CloudFrontClient cloudFrontClient,
final String publicKeyId) {
    GetPublicKeyResponse getResponse = cloudFrontClient.getPublicKey(b ->
b.id(publicKeyId));

    DeletePublicKeyResponse deleteResponse =
cloudFrontClient.deletePublicKey(builder -> builder
        .id(publicKeyId)
        .ifMatch(getResponse.eTag()));

    if (deleteResponse.sdkHttpResponse().isSuccessful()) {
        logger.info("Successfully deleted Public Key [{}]", publicKeyId);
    }
}
}

```

 - [DeleteKeyGroup](#)
 - [DeleteOriginAccessControl](#)
 - [DeletePublicKey](#)

Sign URLs and cookies

The following code example shows how to create signed URLs and cookies that allow access to restricted resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use the [CannedSignerRequest](#) class to sign URLs or cookies with a *canned* policy.

```
import software.amazon.awssdk.services.cloudfront.model.CannedSignerRequest;

import java.net.URL;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.time.Instant;
import java.time.temporal.ChronoUnit;

public class CreateCannedPolicyRequest {

    public static CannedSignerRequest createRequestForCannedPolicy(String
distributionDomainName,
        String fileNameToUpload,
        String privateKeyFullPath, String publicKeyId) throws Exception {
        String protocol = "https";
        String resourcePath = "/" + fileNameToUpload;

        String cloudFrontUrl = new URL(protocol, distributionDomainName,
resourcePath).toString();
        Instant expirationDate = Instant.now().plus(7, ChronoUnit.DAYS);
        Path path = Paths.get(privateKeyFullPath);

        return CannedSignerRequest.builder()
            .resourceUrl(cloudFrontUrl)
            .privateKey(path)
            .keyPairId(publicKeyId)
            .expirationDate(expirationDate)
            .build();
    }
}
```

```
}  
}
```

Use the [CustomSignerRequest](#) class to sign URLs or cookies with a *custom* policy. The `activeDate` and `ipRange` are optional methods.

```
import software.amazon.awssdk.services.cloudfront.model.CustomSignerRequest;  
  
import java.net.URL;  
import java.nio.file.Path;  
import java.nio.file.Paths;  
import java.time.Instant;  
import java.time.temporal.ChronoUnit;  
  
public class CreateCustomPolicyRequest {  
  
    public static CustomSignerRequest createRequestForCustomPolicy(String  
distributionDomainName,  
        String fileNameToUpload,  
        String privateKeyFullPath, String publicKeyId) throws Exception {  
        String protocol = "https";  
        String resourcePath = "/" + fileNameToUpload;  
  
        String cloudFrontUrl = new URL(protocol, distributionDomainName,  
resourcePath).toString();  
        Instant expireDate = Instant.now().plus(7, ChronoUnit.DAYS);  
        // URL will be accessible tomorrow using the signed URL.  
        Instant activeDate = Instant.now().plus(1, ChronoUnit.DAYS);  
        Path path = Paths.get(privateKeyFullPath);  
  
        return CustomSignerRequest.builder()  
            .resourceUrl(cloudFrontUrl)  
            .privateKey(path)  
            .keyPairId(publicKeyId)  
            .expirationDate(expireDate)  
            .activeDate(activeDate) // Optional.  
            // .ipRange("192.168.0.1/24") // Optional.  
            .build();  
    }  
}
```

The following example demonstrates the use of the [CloudFrontUtilities](#) class to produce signed cookies and URLs. [View](#) this code example on GitHub.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontUtilities;
import software.amazon.awssdk.services.cloudfront.cookie.CookiesForCannedPolicy;
import software.amazon.awssdk.services.cloudfront.cookie.CookiesForCustomPolicy;
import software.amazon.awssdk.services.cloudfront.model.CannedSignerRequest;
import software.amazon.awssdk.services.cloudfront.model.CustomSignerRequest;
import software.amazon.awssdk.services.cloudfront.url.SignedUrl;

public class SigningUtilities {
    private static final Logger logger =
        LoggerFactory.getLogger(SigningUtilities.class);
    private static final CloudFrontUtilities cloudFrontUtilities =
        CloudFrontUtilities.create();

    public static SignedUrl signUrlForCannedPolicy(CannedSignerRequest
        cannedSignerRequest) {
        SignedUrl signedUrl =
            cloudFrontUtilities.getSignedUrlWithCannedPolicy(cannedSignerRequest);
        logger.info("Signed URL: [{}]", signedUrl.url());
        return signedUrl;
    }

    public static SignedUrl signUrlForCustomPolicy(CustomSignerRequest
        customSignerRequest) {
        SignedUrl signedUrl =
            cloudFrontUtilities.getSignedUrlWithCustomPolicy(customSignerRequest);
        logger.info("Signed URL: [{}]", signedUrl.url());
        return signedUrl;
    }

    public static CookiesForCannedPolicy
        getCookiesForCannedPolicy(CannedSignerRequest cannedSignerRequest) {
        CookiesForCannedPolicy cookiesForCannedPolicy = cloudFrontUtilities
            .getCookiesForCannedPolicy(cannedSignerRequest);
        logger.info("Cookie EXPIRES header [{}]",
            cookiesForCannedPolicy.expiresHeaderValue());
        logger.info("Cookie KEYPAIR header [{}]",
            cookiesForCannedPolicy.keyPairIdHeaderValue());
    }
}
```

```
        logger.info("Cookie SIGNATURE header [{}]",
cookiesForCannedPolicy.signatureHeaderValue());
        return cookiesForCannedPolicy;
    }

    public static CookiesForCustomPolicy
getCookiesForCustomPolicy(CustomSignerRequest customSignerRequest) {
        CookiesForCustomPolicy cookiesForCustomPolicy = cloudFrontUtilities
            .getCookiesForCustomPolicy(customSignerRequest);
        logger.info("Cookie POLICY header [{}]",
cookiesForCustomPolicy.policyHeaderValue());
        logger.info("Cookie KEYPAIR header [{}]",
cookiesForCustomPolicy.keyPairIdHeaderValue());
        logger.info("Cookie SIGNATURE header [{}]",
cookiesForCustomPolicy.signatureHeaderValue());
        return cookiesForCustomPolicy;
    }
}
```

CloudWatch examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudWatch.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsRequest;
import software.amazon.awssdk.services.cloudwatch.paginators.ListMetricsIterable;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloService {
    public static void main(String[] args) {
        final String usage = ""

                Usage:
                <namespace>\s

                Where:
                namespace - The namespace to filter against (for example, AWS/
EC2).\s

                """;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String namespace = args[0];
        Region region = Region.US_EAST_1;
        CloudWatchClient cw = CloudWatchClient.builder()
```

```
        .region(region)
        .build();

    listMets(cw, namespace);
    cw.close();
}

public static void listMets(CloudWatchClient cw, String namespace) {
    try {
        ListMetricsRequest request = ListMetricsRequest.builder()
            .namespace(namespace)
            .build();

        ListMetricsIterable listRes = cw.listMetricsPaginator(request);
        listRes.stream()
            .flatMap(r -> r.metrics().stream())
            .forEach(metrics -> System.out.println(" Retrieved metric is: "
+ metrics.metricName()));

    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
}
```

- For API details, see [ListMetrics](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)
- [Scenarios](#)

Basics

Learn the basics

The following code example shows how to:

- List CloudWatch namespaces and metrics.

- Get statistics for a metric and for estimated billing.
- Create and update a dashboard.
- Create and add data to a metric.
- Create and trigger an alarm, then view alarm history.
- Add an anomaly detector.
- Get a metric image, then clean up resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario demonstrating CloudWatch features.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 */
```

```

* For more information, see the following documentation topic:
*
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
*
* To enable billing metrics and statistics for this example, make sure billing
* alerts are enabled for your account:
* https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/monitor\_estimated\_charges\_with\_cloudwatch.html#turning\_on\_billing\_metrics
*
* This Java code example performs the following tasks:
*
* 1. List available namespaces from Amazon CloudWatch.
* 2. List available metrics within the selected Namespace.
* 3. Get statistics for the selected metric over the last day.
* 4. Get CloudWatch estimated billing for the last week.
* 5. Create a new CloudWatch dashboard with metrics.
* 6. List dashboards using a paginator.
* 7. Create a new custom metric by adding data for it.
* 8. Add the custom metric to the dashboard.
* 9. Create an alarm for the custom metric.
* 10. Describe current alarms.
* 11. Get current data for the new custom metric.
* 12. Push data into the custom metric to trigger the alarm.
* 13. Check the alarm state using the action DescribeAlarmsForMetric.
* 14. Get alarm history for the new alarm.
* 15. Add an anomaly detector for the custom metric.
* 16. Describe current anomaly detectors.
* 17. Get a metric image for the custom metric.
* 18. Clean up the Amazon CloudWatch resources.
*/

```

Amazon CloudWatch is a comprehensive monitoring and observability service

provided by Amazon Web Services (AWS). It is designed to help you monitor your

AWS resources, applications, and services, as well as on-premises resources,

in real-time.

CloudWatch collects and tracks various types of data, including metrics,

logs, and events, from your AWS and on-premises resources. It allows you to set alarms and automatically respond to changes in your environment, enabling you to quickly identify and address issues before they impact your applications or services.

With CloudWatch, you can gain visibility into your entire infrastructure, from the cloud to the edge, and use this information to make informed decisions and optimize your resource utilization.

This scenario guides you through how to perform Amazon CloudWatch tasks by using the

AWS SDK for Java v2. Let's get started...

Scenarios

Monitor DynamoDB performance

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- CloudWatch
- DynamoDB

CloudWatch Events examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudWatch Events.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Amazon Cognito Identity Provider examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Cognito Identity Provider.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Cognito

The following code examples show how to get started using Amazon Cognito.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.regions.Region;
import
    software.amazon.awssdk.services.cognitoidentityprovider.CognitoIdentityProviderClient;
import
    software.amazon.awssdk.services.cognitoidentityprovider.model.CognitoIdentityProviderException;
import
    software.amazon.awssdk.services.cognitoidentityprovider.model.ListUserPoolsResponse;
import
    software.amazon.awssdk.services.cognitoidentityprovider.model.ListUserPoolsRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *

Actions

AdminGetUser

The following code example shows how to use AdminGetUser.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void getAdminUser(CognitoIdentityProviderClient
    identityProviderClient, String userName,
        String poolId) {
```

```
    try {
        AdminGetUserRequest userRequest = AdminGetUserRequest.builder()
            .username(userName)
            .userPoolId(poolId)
            .build();

        AdminGetUserResponse response =
identityProviderClient.adminGetUser(userRequest);
        System.out.println("User status " + response.userStatusAsString());

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [AdminGetUser](#) in *AWS SDK for Java 2.x API Reference*.

AdminInitiateAuth

The following code example shows how to use AdminInitiateAuth.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static AdminInitiateAuthResponse
initiateAuth(CognitoIdentityProviderClient identityProviderClient,
    String clientId, String userName, String password, String userPoolId) {
    try {
        Map<String, String> authParameters = new HashMap<>();
        authParameters.put("USERNAME", userName);
        authParameters.put("PASSWORD", password);

        AdminInitiateAuthRequest authRequest =
AdminInitiateAuthRequest.builder()
```

```

        .clientId(clientId)
        .userPoolId(userPoolId)
        .authParameters(authParameters)
        .authFlow(AuthFlowType.ADMIN_USER_PASSWORD_AUTH)
        .build();

    AdminInitiateAuthResponse response =
identityProviderClient.adminInitiateAuth(authRequest);
    System.out.println("Result Challenge is : " + response.challengeName());
    return response;

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}

```

- For API details, see [AdminInitiateAuth](#) in *AWS SDK for Java 2.x API Reference*.

AdminRespondToAuthChallenge

The following code example shows how to use AdminRespondToAuthChallenge.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

// Respond to an authentication challenge.
public static void adminRespondToAuthChallenge(CognitoIdentityProviderClient
identityProviderClient,
        String userName, String clientId, String mfaCode, String session) {
    System.out.println("SOFTWARE_TOKEN_MFA challenge is generated");
    Map<String, String> challengeResponses = new HashMap<>();

    challengeResponses.put("USERNAME", userName);
}

```

```

        challengeResponses.put("SOFTWARE_TOKEN_MFA_CODE", mfaCode);

        AdminRespondToAuthChallengeRequest respondToAuthChallengeRequest =
AdminRespondToAuthChallengeRequest.builder()
            .challengeName(ChallengeNameType.SOFTWARE_TOKEN_MFA)
            .clientId(clientId)
            .challengeResponses(challengeResponses)
            .session(session)
            .build();

        AdminRespondToAuthChallengeResponse respondToAuthChallengeResult =
identityProviderClient
            .adminRespondToAuthChallenge(respondToAuthChallengeRequest);
        System.out.println("respondToAuthChallengeResult.getAuthenticationResult()"
            + respondToAuthChallengeResult.authenticationResult());
    }

```

- For API details, see [AdminRespondToAuthChallenge](#) in *AWS SDK for Java 2.x API Reference*.

AssociateSoftwareToken

The following code example shows how to use AssociateSoftwareToken.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

    public static String getSecretForAppMFA(CognitoIdentityProviderClient
identityProviderClient, String session) {
        AssociateSoftwareTokenRequest softwareTokenRequest =
AssociateSoftwareTokenRequest.builder()
            .session(session)
            .build();

        AssociateSoftwareTokenResponse tokenResponse = identityProviderClient
            .associateSoftwareToken(softwareTokenRequest);
        String secretCode = tokenResponse.secretCode();
    }

```

```
        System.out.println("Enter this token into Google Authenticator");
        System.out.println(secretCode);
        return tokenResponse.session();
    }
```

- For API details, see [AssociateSoftwareToken](#) in *AWS SDK for Java 2.x API Reference*.

ConfirmSignUp

The following code example shows how to use `ConfirmSignUp`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void confirmSignUp(CognitoIdentityProviderClient
identityProviderClient, String clientId, String code,
    String userName) {
    try {
        ConfirmSignUpRequest signUpRequest = ConfirmSignUpRequest.builder()
            .clientId(clientId)
            .confirmationCode(code)
            .username(userName)
            .build();

        identityProviderClient.confirmSignUp(signUpRequest);
        System.out.println(userName + " was confirmed");

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

ResendConfirmationCode

The following code example shows how to use ResendConfirmationCode.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void resendConfirmationCode(CognitoIdentityProviderClient
identityProviderClient, String clientId,
    String userName) {
    try {
        ResendConfirmationCodeRequest codeRequest =
ResendConfirmationCodeRequest.builder()
            .clientId(clientId)
            .username(userName)
            .build();

        ResendConfirmationCodeResponse response =
identityProviderClient.resendConfirmationCode(codeRequest);
        System.out.println("Method of delivery is " +
response.codeDeliveryDetails().deliveryMediumAsString());

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [ResendConfirmationCode](#) in *AWS SDK for Java 2.x API Reference*.

SignUp

The following code example shows how to use SignUp.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void signUp(CognitoIdentityProviderClient identityProviderClient,
String clientId, String userName,
    String password, String email) {
    AttributeType userAttrs = AttributeType.builder()
        .name("email")
        .value(email)
        .build();

    List<AttributeType> userAttrsList = new ArrayList<>();
    userAttrsList.add(userAttrs);
    try {
        SignUpRequest signUpRequest = SignUpRequest.builder()
            .userAttributes(userAttrsList)
            .username(userName)
            .clientId(clientId)
            .password(password)
            .build();

        identityProviderClient.signUp(signUpRequest);
        System.out.println("User has been signed up ");

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [SignUp](#) in *AWS SDK for Java 2.x API Reference*.

VerifySoftwareToken

The following code example shows how to use `VerifySoftwareToken`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// Verify the TOTP and register for MFA.
public static void verifyTOTP(CognitoIdentityProviderClient
identityProviderClient, String session, String code) {
    try {
        VerifySoftwareTokenRequest tokenRequest =
VerifySoftwareTokenRequest.builder()
            .userCode(code)
            .session(session)
            .build();

        VerifySoftwareTokenResponse verifyResponse =
identityProviderClient.verifySoftwareToken(tokenRequest);
        System.out.println("The status of the token is " +
verifyResponse.statusAsString());

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [VerifySoftwareToken](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Sign up a user with a user pool that requires MFA

The following code example shows how to:

- Sign up and confirm a user with a username, password, and email address.
- Set up multi-factor authentication by associating an MFA application with the user.

- Sign in by using a password and an MFA code.

SDK for Java 2.x

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * TIP: To set up the required user pool, run the AWS Cloud Development Kit (AWS
 * CDK) script provided in this GitHub repo at
 * resources/cdk/cognito\_scenario\_user\_pool\_with\_mfa.
 *
 * This code example performs the following operations:
 *
 * 1. Invokes the signUp method to sign up a user.
 * 2. Invokes the adminGetUser method to get the user's confirmation status.
 * 3. Invokes the ResendConfirmationCode method if the user requested another
 * code.
 * 4. Invokes the confirmSignUp method.
 * 5. Invokes the AdminInitiateAuth to sign in. This results in being prompted
 * to set up TOTP (time-based one-time password). (The response is
 * "ChallengeName": "MFA_SETUP").
 * 6. Invokes the AssociateSoftwareToken method to generate a TOTP MFA private
 * key. This can be used with Google Authenticator.
 * 7. Invokes the VerifySoftwareToken method to verify the TOTP and register for
 * MFA.
 * 8. Invokes the AdminInitiateAuth to sign in again. This results in being
 * prompted to submit a TOTP (Response: "ChallengeName": "SOFTWARE_TOKEN_MFA").
 * 9. Invokes the AdminRespondToAuthChallenge to get back a token.
 */

Amazon Comprehend examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Comprehend.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Scenarios

Building an Amazon Lex chatbot

The following code example shows how to create a chatbot to engage your website visitors.

SDK for Java 2.x

Shows how to use the Amazon Lex API to create a Chatbot within a web application to engage your web site visitors.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Comprehend
- Amazon Lex
- Amazon Translate

Create a messaging application

The following code example shows how to create a messaging application by using Amazon SQS.

SDK for Java 2.x

Shows how to use the Amazon SQS API to develop a Spring REST API that sends and retrieves messages.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Amazon Comprehend
- Amazon SQS

Create an application to analyze customer feedback

The following code example shows how to create an application that analyzes customer comment cards, translates them from their original language, determines their sentiment, and generates an audio file from the translated text.

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in [GitHub](#).

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Firehose examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Firehose.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

Actions

PutRecord

The following code example shows how to use PutRecord.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Puts a record to the specified Amazon Kinesis Data Firehose delivery stream.
 *
 * @param record The record to be put to the delivery stream. The record must be
 a {@link Map} of String keys and Object values.
 * @param deliveryStreamName The name of the Amazon Kinesis Data Firehose
 delivery stream to which the record should be put.
 * @throws IllegalArgumentException if the input record or delivery stream name
 is null or empty.
 * @throws RuntimeException if there is an error putting the record to the
 delivery stream.
 */
public static void putRecord(Map<String, Object> record, String
deliveryStreamName) {
    if (record == null || deliveryStreamName == null ||
deliveryStreamName.isEmpty()) {
        throw new IllegalArgumentException("Invalid input: record or delivery
stream name cannot be null/empty");
    }
}
```

```

    try {
        String jsonRecord = new ObjectMapper().writeValueAsString(record);
        Record firehoseRecord = Record.builder()

            .data(SdkBytes.fromByteArray(jsonRecord.getBytes(StandardCharsets.UTF_8)))
                .build();

        PutRecordRequest putRecordRequest = PutRecordRequest.builder()
            .deliveryStreamName(deliveryStreamName)
            .record(firehoseRecord)
            .build();

        getFirehoseClient().putRecord(putRecordRequest);
        System.out.println("Record sent: " + jsonRecord);
    } catch (Exception e) {
        throw new RuntimeException("Failed to put record: " + e.getMessage(),
e);
    }
}

```

Serverless examples

Invoke a Lambda function from a Amazon DocumentDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DocumentDB change stream. The function retrieves the DocumentDB payload and logs the record contents.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming a Amazon DocumentDB event with Lambda using Java.

```
import java.util.List;
import java.util.Map;

import com.amazonaws.services.lambda.runtime.Context;
```

```
import com.amazonaws.services.lambda.runtime.RequestHandler;

public class Example implements RequestHandler<Map<String, Object>, String> {

    @SuppressWarnings("unchecked")
    @Override
    public String handleRequest(Map<String, Object> event, Context context) {
        List<Map<String, Object>> events = (List<Map<String, Object>>)
event.get("events");
        for (Map<String, Object> record : events) {
            Map<String, Object> eventData = (Map<String, Object>)
record.get("event");
            processEventData(eventData);
        }

        return "OK";
    }

    @SuppressWarnings("unchecked")
    private void processEventData(Map<String, Object> eventData) {
        String operationType = (String) eventData.get("operationType");
        System.out.println("operationType: %s".formatted(operationType));

        Map<String, Object> ns = (Map<String, Object>) eventData.get("ns");

        String db = (String) ns.get("db");
        System.out.println("db: %s".formatted(db));
        String coll = (String) ns.get("coll");
        System.out.println("coll: %s".formatted(coll));

        Map<String, Object> fullDocument = (Map<String, Object>)
eventData.get("fullDocument");
        System.out.println("fullDocument: %s".formatted(fullDocument));
    }
}
```

DynamoDB examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with DynamoDB.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello DynamoDB

The following code examples show how to get started using DynamoDB.

SDK for Java 2.x

Basics

Learn the basics

The following code example shows how to:

- Create a table that can hold movie data.
- Put, get, and update a single movie in the table.
- Write movie data to the table from a sample JSON file.
- Query for movies that were released in a given year.
- Scan for movies that were released in a range of years.
- Delete a movie from the table, then delete the table.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a DynamoDB table.

```
// Create a table with a Sort key.
public static void createTable(DynamoDbClient ddb, String tableName) {
    DynamoDbWaiter dbWaiter = ddb.waiter();
    ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<>();

    // Define attributes.
    attributeDefinitions.add(AttributeDefinition.builder()
        .attributeName("year")
        .attributeType("N")
        .build());

    attributeDefinitions.add(AttributeDefinition.builder()
        .attributeName("title")
        .attributeType("S")
        .build());

    ArrayList<KeySchemaElement> tableKey = new ArrayList<>();
    KeySchemaElement key = KeySchemaElement.builder()
        .attributeName("year")
        .keyType(KeyType.HASH)
        .build();

    KeySchemaElement key2 = KeySchemaElement.builder()
        .attributeName("title")
        .keyType(KeyType.RANGE)
        .build();

    // Add KeySchemaElement objects to the list.
    tableKey.add(key);
    tableKey.add(key2);

    CreateTableRequest request = CreateTableRequest.builder()
        .keySchema(tableKey)
```

```

        .provisionedThroughput(ProvisionedThroughput.builder()
            .readCapacityUnits(10L)
            .writeCapacityUnits(10L)
            .build())
        .attributeDefinitions(attributeDefinitions)
        .tableName(tableName)
        .build();

    try {
        CreateTableResponse response = ddb.createTable(request);
        DescribeTableRequest tableRequest = DescribeTableRequest.builder()
            .tableName(tableName)
            .build();

        // Wait until the Amazon DynamoDB table is created.
        WaiterResponse<DescribeTableResponse> waiterResponse =
dbWaiter.waitUntilTableExists(tableRequest);
        waiterResponse.matched().response().ifPresent(System.out::println);
        String newTable = response.tableDescription().tableName();
        System.out.println("The " + newTable + " was successfully created.");

    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

```

Create a helper function to download and extract the sample JSON file.

```

// Load data into the table.
public static void loadData(DynamoDbClient ddb, String tableName, String
fileName) throws IOException {
    DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
        .dynamoDbClient(ddb)
        .build();

    DynamoDbTable<Movies> mappedTable = enhancedClient.table("Movies",
TableSchema.fromBean(Movies.class));
    JsonParser parser = new JsonFactory().createParser(new File(fileName));
    com.fasterxml.jackson.databind.JsonNode rootNode = new
ObjectMapper().readTree(parser);
    Iterator<JsonNode> iter = rootNode.iterator();

```

```
ObjectNode currentNode;
int t = 0;
while (iter.hasNext()) {
    // Only add 200 Movies to the table.
    if (t == 200)
        break;
    currentNode = (ObjectNode) iter.next();

    int year = currentNode.path("year").asInt();
    String title = currentNode.path("title").asText();
    String info = currentNode.path("info").toString();

    Movies movies = new Movies();
    movies.setYear(year);
    movies.setTitle(title);
    movies.setInfo(info);

    // Put the data into the Amazon DynamoDB Movie table.
    mappedTable.putItem(movies);
    t++;
}
}
```

Get an item from a table.

```
public static void getItem(DynamoDbClient ddb) {

    HashMap<String, AttributeValue> keyToGet = new HashMap<>();
    keyToGet.put("year", AttributeValue.builder()
        .n("1933")
        .build());

    keyToGet.put("title", AttributeValue.builder()
        .s("King Kong")
        .build());

    GetItemRequest request = GetItemRequest.builder()
        .key(keyToGet)
        .tableName("Movies")
        .build();

    try {
```

```

        Map<String, AttributeValue> returnedItem = ddb.getItem(request).item();

        if (returnedItem != null) {
            Set<String> keys = returnedItem.keySet();
            System.out.println("Amazon DynamoDB table attributes: \n");

            for (String key1 : keys) {
                System.out.format("%s: %s\n", key1,
returnedItem.get(key1).toString());
            }
        } else {
            System.out.format("No item found with the key %s!\n", "year");
        }

    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

```

Full example.

```

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs these tasks:
 *
 * 1. Creates the Amazon DynamoDB Movie table with partition and sort key.
 * 2. Puts data into the Amazon DynamoDB table from a JSON document using the
 * Enhanced client.
 * 3. Gets data from the Movie table.
 * 4. Adds a new item.
 * 5. Updates an item.
 * 6. Uses a Scan to query items using the Enhanced client.
 * 7. Queries all items where the year is 2013 using the Enhanced Client.
 * 8. Deletes the table.
 */

    try (DynamoDbClient ddb = DynamoDbClient.builder()
        .region(region)
        .build()) {
        final UpdateTimeToLiveResponse response = ddb.updateTimeToLive(request);
        System.out.println(tableName + " had its TTL successfully updated. The
request id is "
            + response.responseMetadata().requestId());
    } catch (ResourceNotFoundException e) {
        System.err.format("Error: The Amazon DynamoDB table \"%s\" can't be
found.\n", tableName);

```

```
        System.exit(1);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    System.out.println("Done!");
```

- For API details, see [UpdateTimeToLive](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build an app to submit data to a DynamoDB table

The following code example shows how to build an application that submits data to an Amazon DynamoDB table and notifies you when a user updates the table.

SDK for Java 2.x

Shows how to create a dynamic web application that submits data using the Amazon DynamoDB Java API and sends a text message using the Amazon Simple Notification Service Java API.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SNS

Conditionally update an item's TTL

The following code example shows how to conditionally update an item's TTL.

SDK for Java 2.x

```
package com.amazon.samplelib.ttl;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
```

```

import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

Create a table with warm throughput enabled

The following code example shows how to create a table with warm throughput enabled.

SDK for Java 2.x

Create DynamoDB table with warm throughput setting.

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.GlobalSecondaryIndex;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.Projection;
import software.amazon.awssdk.services.dynamodb.model.ProjectionType;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
```

```
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.WarmThroughput;

    public static WarmThroughput buildWarmThroughput(final Long readUnitsPerSecond,
                                                    final Long writeUnitsPerSecond)
    {
        return WarmThroughput.builder()
            .readUnitsPerSecond(readUnitsPerSecond)

Create a web application to track DynamoDB data

The following code example shows how to create a web application that tracks work items in an Amazon DynamoDB table and uses Amazon Simple Email Service (Amazon SES) to send reports.

SDK for Java 2.x

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SES

Create an item with a TTL

The following code example shows how to create an item with TTL.

SDK for Java 2.x

```
package com.amazon.samplelib.ttl;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.PutItemRequest;
import software.amazon.awssdk.services.dynamodb.model.PutItemResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import software.amazon.awssdk.utils.ImmutableMap;

import java.io.Serializable;
import java.util.Map;
import java.util.Optional;

public class CreateTTL {
    public static void main(String[] args) {
        final String usage = ""
            Usage:
                <tableName> <primaryKey> <sortKey> <region>
            Where:
                tableName - The Amazon DynamoDB table being queried.
```

```

        primaryKey - The name of the primary key. Also known as the hash
or partition key.
        sortKey - The name of the sort key. Also known as the range
attribute.
        region (optional) - The AWS region that the Amazon DynamoDB
table is located in. (Default: us-east-1)
        """;
    // Optional "region" parameter - if args list length is NOT 3 or 4, short-
circuit exit.
    if (!(args.length == 3 || args.length == 4)) {

Detect PPE in images

The following code example shows how to build an app that uses Amazon Rekognition to detect Personal Protective Equipment (PPE) in images.

SDK for Java 2.x

Shows how to create an AWS Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

Monitor DynamoDB performance

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- CloudWatch
- DynamoDB

Query a table by using batches of PartiQL statements

The following code example shows how to:

- Get a batch of items by running multiple SELECT statements.
- Add a batch of items by running multiple INSERT statements.
- Update a batch of items by running multiple UPDATE statements.
- Delete a batch of items by running multiple DELETE statements.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Query a table using PartiQL

The following code example shows how to:

- Get an item by running a SELECT statement.
- Add an item by running an INSERT statement.
- Update an item by running an UPDATE statement.
- Delete an item by running a DELETE statement.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public class ScenarioPartiQ {

Use Step Functions to invoke Lambda functions

The following code example shows how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

Serverless examples

Invoke a Lambda function from a DynamoDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DynamoDB stream. The function retrieves the DynamoDB payload and logs the record contents.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming a DynamoDB event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.DynamodbEvent;
import
    com.amazonaws.services.lambda.runtime.events.DynamodbEvent.DynamodbStreamRecord;
import com.google.gson.Gson;
import com.google.gson.GsonBuilder;

public class example implements RequestHandler<DynamodbEvent, Void> {

    private static final Gson GSON = new GsonBuilder().setPrettyPrinting().create();

    @Override
    public Void handleRequest(DynamodbEvent event, Context context) {
        System.out.println(GSON.toJson(event));
        event.getRecords().forEach(this::logDynamoDBRecord);
    }
}
```

```
        return null;
    }

    private void logDynamoDBRecord(DynamodbStreamRecord record) {
        System.out.println(record.getEventID());
        System.out.println(record.getEventName());
        System.out.println("DynamoDB Record: " + GSON.toJson(record.getDynamodb()));
    }
}
```

Reporting batch item failures for Lambda functions with a DynamoDB trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a DynamoDB stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Reporting DynamoDB batch item failures with Lambda using Java.

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Amazon EC2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon EC2.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon EC2

The following code examples show how to get started using Amazon EC2.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
```

```

    * Asynchronously describes the security groups for the specified group ID.
    *
    * @param groupName the name of the security group to describe
    * @return a {@link CompletableFuture} that represents the asynchronous
operation
    *       of describing the security groups. The future will complete with a
    *       {@link DescribeSecurityGroupsResponse} object that contains the
    *       security group information.
    */
    public CompletableFuture<String> describeSecurityGroupArnByNameAsync(String
groupName) {
        DescribeSecurityGroupsRequest request =
DescribeSecurityGroupsRequest.builder()
            .groupNames(groupName)
            .build();

        DescribeSecurityGroupsPublisher paginator =
getAsyncClient().describeSecurityGroupsPaginator(request);
        AtomicReference<String> groupIdRef = new AtomicReference<>();
        return paginator.subscribe(response -> {
            response.securityGroups().stream()
                .filter(securityGroup ->
securityGroup.groupName().equals(groupName))
                .findFirst()
                .ifPresent(securityGroup ->
groupIdRef.set(securityGroup.groupId()));
        }).thenApply(v -> {
            String groupId = groupIdRef.get();
            if (groupId == null) {
                throw new RuntimeException("No security group found with the name: "
+ groupName);
            }
            return groupId;
        }).exceptionally(ex -> {
            logger.info("Failed to describe security group: " + ex.getMessage());
            throw new RuntimeException("Failed to describe security group", ex);
        });
    }
}

```

- [Scenarios](#)

Basics

Learn the basics

The following code example shows how to:

- Create a key pair and security group.
- Select an Amazon Machine Image (AMI) and compatible instance type, then create an instance.
- Stop and restart the instance.
- Associate an Elastic IP address with your instance.
- Connect to your instance with SSH, then clean up resources.

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Creates an RSA key pair and saves the private key data as a .pem file.
 * 2. Lists key pairs.
 * 3. Creates a security group for the default VPC.
 * 4. Displays security group information.
 * 5. Gets a list of Amazon Linux 2 AMIs and selects one.
 * 6. Gets additional information about the image.
 * 7. Gets a list of instance types that are compatible with the selected AMI's
 * architecture.
 * 8. Creates an instance with the key pair, security group, AMI, and an
 * instance type.
 * 9. Displays information about the instance.
 * 10. Stops the instance and waits for it to stop.
 * 11. Starts the instance and waits for it to start.
 * 12. Allocates an Elastic IP address and associates it with the instance.
 * 13. Displays SSH connection info for the instance.
 * 14. Disassociates and deletes the Elastic IP address.
 * 15. Terminates the instance and waits for it to terminate.
 * 16. Deletes the security group.
 * 17. Deletes the key pair.
 */

```

```
    Amazon Elastic Compute Cloud (EC2) is a web service that provides  
secure, resizable compute
```

```
    capacity in the cloud. It allows developers and organizations to easily  
launch and manage
```

```
    virtual server instances, known as EC2 instances, to run their  
applications.
```

```
    EC2 provides a wide range of instance types, each with different  
compute, memory,
```

```
    and storage capabilities, to meet the diverse needs of various  
workloads. Developers
```

```
    can choose the appropriate instance type based on their application's  
requirements,
```

```
    such as high-performance computing, memory-intensive tasks, or GPU-  
accelerated workloads.
```

```
    The `Ec2AsyncClient` interface in the AWS SDK for Java 2.x provides a  
set of methods to
```

```
    programmatically interact with the Amazon EC2 service. This allows  
developers to
```

```
    automate the provisioning, management, and monitoring of EC2 instances  
as part of their
```

application deployment pipelines. With EC2, teams can focus on building and deploying their applications without having to worry about the underlying infrastructure required to host and manage physical servers.

This scenario walks you through how to perform key operations for this service.

    TerminateInstancesRequest terminateRequest =
    TerminateInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    CompletableFuture<TerminateInstancesResponse> responseFuture =
    getAsyncClient().terminateInstances(terminateRequest);
    return responseFuture.thenCompose(terminateResponse -> {
        if (terminateResponse == null) {
            throw new RuntimeException("No response received for terminating
            instance " + instanceId);
        }
        System.out.println("Going to terminate an EC2 instance and use a waiter
        to wait for it to be in terminated state");
        return getAsyncClient().waiter()
            .waitUntilInstanceTerminated(r -> r.instanceIds(instanceId))
            .thenApply(waiterResponse -> null);
    }).exceptionally(throwable -> {
        // Handle any exceptions that occurred during the async call
        throw new RuntimeException("Failed to terminate EC2 instance: " +
        throwable.getMessage(), throwable);
    });
}
```

- For API details, see [TerminateInstances](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

Note

Amazon ECR examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon ECR.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon ECR

The following code examples show how to get started using Amazon ECR.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ecr.EcrClient;
import software.amazon.awssdk.services.ecr.model.EcrException;
import software.amazon.awssdk.services.ecr.model.ListImagesRequest;
import software.amazon.awssdk.services.ecr.paginators.ListImagesIterable;

public class HelloECR {

    public static void main(String[] args) {
        final String usage = ""
            Usage:    <repositoryName>

            Where:
                repositoryName - The name of the Amazon ECR repository.
            "";

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String repoName = args[0];
        EcrClient ecrClient = EcrClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listImageTags(ecrClient, repoName);
    }
}
```

```
public static void listImageTags(EcrClient ecrClient, String repoName){
    ListImagesRequest listImagesPaginator = ListImagesRequest.builder()
        .repositoryName(repoName)
        .build();

    ListImagesIterable imagesIterable =
    ecrClient.listImagesPaginator(listImagesPaginator);
    imagesIterable.stream()
        .flatMap(r -> r.imageIds().stream())
        .forEach(image -> System.out.println("The docker image tag is: "
+image.imageTag()));
    }
}
```

- For API details, see [listImages](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon ECR repository.
- Set repository policies.
- Retrieve repository URIs.
- Get Amazon ECR authorization tokens.
- Set lifecycle policies for Amazon ECR repositories.
- Push a Docker image to an Amazon ECR repository.
- Verify the existence of an image in an Amazon ECR repository.
- List Amazon ECR repositories for your account and get details about them.
- Delete Amazon ECR repositories.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario demonstrating Amazon ECR features.

```
import software.amazon.awssdk.services.ecr.model.EcrException;
import software.amazon.awssdk.services.ecr.model.RepositoryPolicyNotFoundException;

import java.util.Scanner;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example requires an IAM Role that has permissions to interact with
 * the Amazon ECR service.
 *
 * To create an IAM role, see:
 *
 * https://docs.aws.amazon.com/IAM/latest/UserGuide/id\_roles\_create.html
 *
 * This Java scenario example requires a local docker image named echo-text. Without
 * a local image,
 * this Java program will not successfully run. For more information including how
 * to create the local
 * image, see:
 *
 * /getting\_started\_scenarios/ecr\_scenario/README
 */
public class ECRScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    public static void main(String[] args) {
        final String usage = ""
```

```
Usage: <iamRoleARN> <accountId>

Where:
    iamRoleARN - The IAM role ARN that has the necessary permissions to
access and manage the Amazon ECR repository.
    accountId - Your AWS account number.

String localImageName;

Scanner scanner = new Scanner(System.in);
System.out.println("""
    The Amazon Elastic Container Registry (ECR) is a fully-managed Docker
container registry
    service provided by AWS. It allows developers and organizations to
securely
    store, manage, and deploy Docker container images.
    ECR provides a simple and scalable way to manage container images
throughout their lifecycle,
    from building and testing to production deployment.\s

    The `EcrAsyncClient` interface in the AWS SDK for Java 2.x provides a
set of methods to
    programmatically interact with the Amazon ECR service. This allows
developers to
    automate the storage, retrieval, and management of container images as
part of their application
    deployment pipelines. With ECR, teams can focus on building and
deploying their
    applications without having to worry about the underlying
infrastructure required to
    host and manage a container registry.

    This scenario walks you through how to perform key operations for this
service.

    Let's get started...
```

```

    You have two choices:
    1 - Run the entire program.
    2 - Delete an existing Amazon ECR repository named echo-text (created
from a previous execution of
    this program that did not complete).
    """);

while (true) {
    String input = scanner.nextLine();
    if (input.trim().equalsIgnoreCase("1")) {
        System.out.println("Continuing with the program...");
        System.out.println("");
        break;
    } else if (input.trim().equalsIgnoreCase("2")) {
        String repoName = "echo-text";
        ecrActions.deleteECRRepository(repoName);
        return;
    } else {
        // Handle invalid input.
        System.out.println("Invalid input. Please try again.");
    }
}

waitForInputToContinue(scanner);
System.out.println(DASHES);

System.out.println("""
    1. Create an ECR repository.

    The first task is to ensure we have a local Docker image named echo-
text.

    If this image exists, then an Amazon ECR repository is created.

    An ECR repository is a private Docker container repository provided
    by Amazon Web Services (AWS). It is a managed service that makes it easy
    to store, manage, and deploy Docker container images.\s
    """);

// Ensure that a local docker image named echo-text exists.
boolean doesExist = ecrActions.isEchoTextImagePresent();

Amazon ECS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon ECS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Elastic Load Balancing - Version 2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Elastic Load Balancing - Version 2.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Elastic Load Balancing

The following code examples show how to get started using Elastic Load Balancing.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public class HelloLoadBalancer {

    public static void main(String[] args) {
        ElasticLoadBalancingV2Client loadBalancingV2Client =
ElasticLoadBalancingV2Client.builder()
                                .region(Region.US_EAST_1)
                                .build();

        DescribeLoadBalancersResponse loadBalancersResponse =
loadBalancingV2Client
```

```
                .describeLoadBalancers(r -> r.pageSize(10));
        List<LoadBalancer> loadBalancerList =
loadBalancersResponse.loadBalancers();
        for (LoadBalancer lb : loadBalancerList)
            System.out.println("Load Balancer DNS name = " +
lb.dnsName());
    }
}
```

- For API details, see [DescribeLoadBalancers](#) in *AWS SDK for Java 2.x API Reference*.

Actions

CreateListener

The following code example shows how to use `CreateListener`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/*
 * Creates an Elastic Load Balancing load balancer that uses the specified
 * subnets
 * and forwards requests to the specified target group.
 */
public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
    String protocol) {
    try {
        List<String> subnetIdStrings = subnetIds.stream()
```

```
        .map(Subnet::subnetId)
        .collect(Collectors.toList());

    CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
        .subnets(subnetIdStrings)
        .name(lbName)
        .scheme("internet-facing")
        .build();

    // Create and wait for the load balancer to become available.
    CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
    String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

    ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
    DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
        .loadBalancerArns(lbARN)
        .build();

    System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
    WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
        .waitUntilLoadBalancerAvailable(request);
    waiterResponse.matched().response().ifPresent(System.out::println);
    System.out.println("Load Balancer " + lbName + " is available.");

    // Get the DNS name (endpoint) of the load balancer.
    String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
    System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

    // Create a listener for the load balance.
    Action action = Action.builder()
        .targetGroupArn(targetGroupARN)
        .type("forward")
        .build();

    CreateListenerRequest listenerRequest = CreateListenerRequest.builder()

.loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
        .defaultActions(action)
```

```

        .port(port)
        .protocol(protocol)
        .defaultActions(action)
        .build();

        getLoadBalancerClient().createListener(listenerRequest);
        System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
        + targetGroupARN);

        // Return the load balancer DNS name.
        return lbDNSName;

    } catch (ElasticLoadBalancingV2Exception e) {
        e.printStackTrace();
    }
    return "";
}

```

- For API details, see [CreateListener](#) in *AWS SDK for Java 2.x API Reference*.

CreateLoadBalancer

The following code example shows how to use `CreateLoadBalancer`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

/*
 * Creates an Elastic Load Balancing load balancer that uses the specified
 * subnets
 * and forwards requests to the specified target group.
 */
public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
String protocol) {

```

```
try {
    List<String> subnetIdStrings = subnetIds.stream()
        .map(Subnet::subnetId)
        .collect(Collectors.toList());

    CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
    .subnets(subnetIdStrings)
    .name(lbName)
    .scheme("internet-facing")
    .build();

    // Create and wait for the load balancer to become available.
    CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
    String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

    ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
    DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
    .loadBalancerArns(lbARN)
    .build();

    System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
    WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
        .waitUntilLoadBalancerAvailable(request);
    waiterResponse.matched().response().ifPresent(System.out::println);
    System.out.println("Load Balancer " + lbName + " is available.");

    // Get the DNS name (endpoint) of the load balancer.
    String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
    System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

    // Create a listener for the load balance.
    Action action = Action.builder()
        .targetGroupArn(targetGroupARN)
        .type("forward")
        .build();

    CreateListenerRequest listenerRequest = CreateListenerRequest.builder()
```

```

        .loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
        .defaultActions(action)
        .port(port)
        .protocol(protocol)
        .defaultActions(action)
        .build();

        getLoadBalancerClient().createListener(listenerRequest);
        System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
        + targetGroupARN);

        // Return the load balancer DNS name.
        return lbDNSName;

    } catch (ElasticLoadBalancingV2Exception e) {
        e.printStackTrace();
    }
    return "";
}

```

- For API details, see [CreateLoadBalancer](#) in *AWS SDK for Java 2.x API Reference*.

CreateTargetGroup

The following code example shows how to use `CreateTargetGroup`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

/*
 * Creates an Elastic Load Balancing target group. The target group specifies
 * how
 * the load balancer forward requests to instances in the group and how instance

```

```
    * health is checked.
    */
    public String createTargetGroup(String protocol, int port, String vpcId, String
targetGroupName) {
        CreateTargetGroupRequest targetGroupRequest =
CreateTargetGroupRequest.builder()
            .healthCheckPath("/healthcheck")
            .healthCheckTimeoutSeconds(5)
            .port(port)
            .vpcId(vpcId)
            .name(targetGroupName)
            .protocol(protocol)
            .build();

        CreateTargetGroupResponse targetGroupResponse =
getLoadBalancerClient().createTargetGroup(targetGroupRequest);
        String targetGroupArn =
targetGroupResponse.targetGroups().get(0).targetGroupArn();
        String targetGroup =
targetGroupResponse.targetGroups().get(0).targetGroupName();
        System.out.println("The " + targetGroup + " was created with ARN" +
targetGroupArn);
        return targetGroupArn;
    }
}
```

- For API details, see [CreateTargetGroup](#) in *AWS SDK for Java 2.x API Reference*.

DeleteLoadBalancer

The following code example shows how to use DeleteLoadBalancer.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// Deletes a load balancer.
```

```
public void deleteLoadBalancer(String lbName) {
    try {
        // Use a waiter to delete the Load Balancer.
        DescribeLoadBalancersResponse res = getLoadBalancerClient()
            .describeLoadBalancers(describe -> describe.names(lbName));
        ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
        DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
            .loadBalancerArns(res.loadBalancers().get(0).loadBalancerArn())
            .build();

        getLoadBalancerClient().deleteLoadBalancer(
            builder ->
builder.loadBalancerArn(res.loadBalancers().get(0).loadBalancerArn()));
        WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
            .waitUntilLoadBalancersDeleted(request);
        waiterResponse.matched().response().ifPresent(System.out::println);

    } catch (ElasticLoadBalancingV2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
    System.out.println(lbName + " was deleted.");
}
```

- For API details, see [DeleteLoadBalancer](#) in *AWS SDK for Java 2.x API Reference*.

DeleteTargetGroup

The following code example shows how to use DeleteTargetGroup.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// Deletes the target group.
```

```
public void deleteTargetGroup(String targetGroupName) {
    try {
        DescribeTargetGroupsResponse res = getLoadBalancerClient()
            .describeTargetGroups(describe ->
describe.names(targetGroupName));
        getLoadBalancerClient()
            .deleteTargetGroup(builder ->
builder.targetGroupArn(res.targetGroups().get(0).targetGroupArn()));
    } catch (ElasticLoadBalancingV2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
    System.out.println(targetGroupName + " was deleted.");
}
```

- For API details, see [DeleteTargetGroup](#) in *AWS SDK for Java 2.x API Reference*.

DescribeTargetHealth

The following code example shows how to use DescribeTargetHealth.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// Checks the health of the instances in the target group.
public List<TargetHealthDescription> checkTargetHealth(String targetGroupName) {
    DescribeTargetGroupsRequest targetGroupsRequest =
DescribeTargetGroupsRequest.builder()
        .names(targetGroupName)
        .build();

    DescribeTargetGroupsResponse tgResponse =
getLoadBalancerClient().describeTargetGroups(targetGroupsRequest);

    DescribeTargetHealthRequest healthRequest =
DescribeTargetHealthRequest.builder()
```

```
                .targetGroupArn(tgResponse.targetGroups().get(0).targetGroupArn())
                .build();

        DescribeTargetHealthResponse healthResponse =
            getLoadBalancerClient().describeTargetHealth(healthRequest);
        return healthResponse.targetHealthDescriptions();
    }
}
```

- For API details, see [DescribeTargetHealth](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run the interactive scenario at a command prompt.

```

MediaStore examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with MediaStore.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

OpenSearch Service examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with OpenSearch Service.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello OpenSearch Service

The following code example shows how to get started using OpenSearch Service.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import software.amazon.awssdk.services.opensearch.OpenSearchAsyncClient;
import software.amazon.awssdk.services.opensearch.model.ListVersionsRequest;
import java.util.List;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloOpenSearch {
    public static void main(String[] args) {
        try {
            CompletableFuture<Void> future = listVersionsAsync();
            future.join();
            System.out.println("Versions listed successfully.");
        } catch (RuntimeException e) {
            System.err.println("Error occurred while listing versions: " +
                e.getMessage());
        }
    }
}
```

```
}

private static OpenSearchAsyncClient getAsyncClient() {
    return OpenSearchAsyncClient.builder().build();
}

public static CompletableFuture<Void> listVersionsAsync() {
    ListVersionsRequest request = ListVersionsRequest.builder()
        .maxResults(10)
        .build();

    return getAsyncClient().listVersions(request).thenAccept(response -> {
        List<String> versionList = response.versions();
        for (String version : versionList) {
            System.out.println("Version info: " + version);
        }
    }).exceptionally(ex -> {
        // Handle the exception, or propagate it as a RuntimeException
        throw new RuntimeException("Failed to list versions", ex);
    });
}
}
```

- For API details, see [ListVersions](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)

Basics

Learn OpenSearch Service core operations

The following code example shows how to:

- Create an OpenSearch Service domain.
- Provides detailed information about a specific OpenSearch Service domain.
- Lists all the OpenSearch Service domains owned by the account.
- Waits until the OpenSearch Service domain's change status reaches a completed state.

- Modifies the configuration of an existing OpenSearch Service domain.
- Add a tag to the OpenSearch Service domain.
- Lists the tags associated with an OpenSearch Service domain.
- Removes tags from an OpenSearch Service domain.
- Deletes the OpenSearch Service domain.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario demonstrating OpenSearch Service features.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.opensearch.model.*;
import java.util.List;
import java.util.Scanner;
import java.util.concurrent.CompletableFuture;

public class OpenSearchScenario {

    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    private static final Logger logger =
        LoggerFactory.getLogger(OpenSearchScenario.class);
    static Scanner scanner = new Scanner(System.in);

    static OpenSearchActions openSearchActions = new OpenSearchActions();

    public static void main(String[] args) throws Throwable {
        logger.info("""
            Welcome to the Amazon OpenSearch Service Basics Scenario.

            Use the Amazon OpenSearch Service API to create, configure, and manage
            OpenSearch Service domains.
```

The operations exposed by the AWS OpenSearch Service client are focused on managing the OpenSearch Service domains and their configurations, not the data within the domains (such as indexing or querying documents).

For document management, you typically interact directly with the OpenSearch REST API or use other libraries, such as the OpenSearch Java client (<https://opensearch.org/docs/latest/clients/java/>).

```
        Let's get started...
        """);

DeleteDomain

The following code example shows how to use DeleteDomain.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Deletes a specific domain asynchronously.
 * @param domainName the name of the domain to be deleted
 * @return a {@link CompletableFuture} that completes when the domain has been
 deleted
 * or throws a {@link RuntimeException} if the deletion fails
 */
public CompletableFuture<DeleteDomainResponse> deleteSpecificDomainAsync(String
domainName) {
    DeleteDomainRequest domainRequest = DeleteDomainRequest.builder()
        .domainName(domainName)
        .build();

    // Delete domain asynchronously
    return getAsyncClient().deleteDomain(domainRequest)
        .whenComplete((response, exception) -> {
            if (exception != null) {
                throw new RuntimeException("Failed to delete the domain: " +
domainName, exception);
            }
        });
}
```

- For API details, see [DeleteDomain](#) in *AWS SDK for Java 2.x API Reference*.

DescribeDomain

The following code example shows how to use DescribeDomain.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Updates the configuration of a specific domain asynchronously.
 * @param domainName the name of the domain to update
 * @return a {@link CompletableFuture} that represents the asynchronous
 * operation of updating the domain configuration
 */
public CompletableFuture<UpdateDomainConfigResponse>
updateSpecificDomainAsync(String domainName) {
    ClusterConfig clusterConfig = ClusterConfig.builder()
        .instanceCount(3)
        .build();

    UpdateDomainConfigRequest updateDomainConfigRequest =
UpdateDomainConfigRequest.builder()
        .domainName(domainName)
        .clusterConfig(clusterConfig)
        .build();

    return getAsyncClient().updateDomainConfig(updateDomainConfigRequest)
        .whenComplete((response, exception) -> {
            if (exception != null) {
                throw new RuntimeException("Failed to update the domain
configuration", exception);
            }
            // Handle success if needed (e.g., logging or additional actions)
        });
}
```

        .clusterConfig(clusterConfig)
        .build();

    return getAsyncClient().updateDomainConfig(updateDomainConfigRequest)
        .whenComplete((response, exception) -> {

```

```
        if (exception != null) {
            throw new RuntimeException("Failed to update the domain
configuration", exception);
        }
        // Handle success if needed (e.g., logging or additional actions)
    });
}
```

- For API details, see [UpdateDomainConfig](#) in *AWS SDK for Java 2.x API Reference*.

EventBridge examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with EventBridge.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge

The following code examples show how to get started using EventBridge.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloEventBridge {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        EventBridgeClient eventBrClient = EventBridgeClient.builder()
            .region(region)
            .build();

        listBuses(eventBrClient);
        eventBrClient.close();
    }

    public static void listBuses(EventBridgeClient eventBrClient) {
        try {
            ListEventBusesRequest busesRequest = ListEventBusesRequest.builder()
                .limit(10)
                .build();

            ListEventBusesResponse response =
eventBrClient.listEventBuses(busesRequest);
            List<EventBus> buses = response.eventBuses();
            for (EventBus bus : buses) {
                System.out.println("The name of the event bus is: " + bus.name());
                System.out.println("The ARN of the event bus is: " + bus.arn());
            }

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see [ListEventBuses](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)
- [Scenarios](#)

Basics

Learn the basics

The following code example shows how to:

- Create a rule and add a target to it.
- Enable and disable rules.
- List and update rules and targets.
- Send events, then clean up resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * This Java V2 example performs the following tasks with Amazon EventBridge:
 *
 * 1. Creates an AWS Identity and Access Management (IAM) role to use with
 * Amazon EventBridge.
```

- * 2. Amazon Simple Storage Service (Amazon S3) bucket with EventBridge events enabled.
- * 3. Creates a rule that triggers when an object is uploaded to Amazon S3.
- * 4. Lists rules on the event bus.
- * 5. Creates a new Amazon Simple Notification Service (Amazon SNS) topic and lets the user subscribe to it.
- * 6. Adds a target to the rule that sends an email to the specified topic.
- * 7. Creates an EventBridge event that sends an email when an Amazon S3 object is created.
- * 8. Lists Targets.
- * 9. Lists the rules for the same target.
- * 10. Triggers the rule by uploading a file to the Amazon S3 bucket.
- * 11. Disables a specific rule.
- * 12. Checks and print the state of the rule.
- * 13. Adds a transform to the rule to change the text of the email.
- * 14. Enables a specific rule.
- * 15. Triggers the updated rule by uploading a file to the Amazon S3 bucket.
- * 16. Updates the rule to be a custom rule pattern.
- * 17. Sending an event to trigger the rule.
- * 18. Cleans up resources.
- *
- */

Actions

DeleteRule

The following code example shows how to use DeleteRule.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void deleteRuleByName(EventBridgeClient eventBrClient, String
ruleName) {
    DeleteRuleRequest ruleRequest = DeleteRuleRequest.builder()
        .name(ruleName)
        .build();

    eventBrClient.deleteRule(ruleRequest);
    System.out.println("Successfully deleted the rule");
}
```

- For API details, see [DeleteRule](#) in *AWS SDK for Java 2.x API Reference*.

DescribeRule

The following code example shows how to use DescribeRule.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void checkRule(EventBridgeClient eventBrClient, String
eventRuleName) {
    try {
        DescribeRuleRequest ruleRequest = DescribeRuleRequest.builder()
            .name(eventRuleName)
            .build();
```

```
DescribeRuleResponse response = eventBrClient.describeRule(ruleRequest);
System.out.println("The state of the rule is " +
response.stateAsString());

    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [DescribeRule](#) in *AWS SDK for Java 2.x API Reference*.

DisableRule

The following code example shows how to use `DisableRule`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Disable a rule by using its rule name.

```
public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
    try {
        if (!isEnabled) {
            System.out.println("Disabling the rule: " + eventRuleName);
            DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                .name(eventRuleName)
                .build();

            eventBrClient.disableRule(ruleRequest);
        } else {
            System.out.println("Enabling the rule: " + eventRuleName);
            EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                .name(eventRuleName)
                .build();
        }
    }
}
```

```
        eventBrClient.enableRule(ruleRequest);
    }

    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [DisableRule](#) in *AWS SDK for Java 2.x API Reference*.

EnableRule

The following code example shows how to use `EnableRule`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Enable a rule by using its rule name.

```
public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
    try {
        if (!isEnabled) {
            System.out.println("Disabling the rule: " + eventRuleName);
            DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                .name(eventRuleName)
                .build();

            eventBrClient.disableRule(ruleRequest);
        } else {
            System.out.println("Enabling the rule: " + eventRuleName);
            EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                .name(eventRuleName)
                .build();
            eventBrClient.enableRule(ruleRequest);
        }
    }
}
```

```
    }  
  
    } catch (EventBridgeException e) {  
        System.err.println(e.awsErrorDetails().errorMessage());  
        System.exit(1);  
    }  
}
```

- For API details, see [EnableRule](#) in *AWS SDK for Java 2.x API Reference*.

ListRuleNamesByTarget

The following code example shows how to use `ListRuleNamesByTarget`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

List all of the rule names by using the target.

```
public static void listTargetRules(EventBridgeClient eventBrClient, String  
topicArn) {  
    ListRuleNamesByTargetRequest ruleNamesByTargetRequest =  
ListRuleNamesByTargetRequest.builder()  
        .targetArn(topicArn)  
        .build();  
  
    ListRuleNamesByTargetResponse response =  
eventBrClient.listRuleNamesByTarget(ruleNamesByTargetRequest);  
    List<String> rules = response.ruleNames();  
    for (String rule : rules) {  
        System.out.println("The rule name is " + rule);  
    }  
}
```

- For API details, see [ListRuleNamesByTarget](#) in *AWS SDK for Java 2.x API Reference*.

ListRules

The following code example shows how to use `ListRules`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Enable a rule by using its rule name.

```
public static void listRules(EventBridgeClient eventBrClient) {
    try {
        ListRulesRequest rulesRequest = ListRulesRequest.builder()
            .eventBusName("default")
            .limit(10)
            .build();

        ListRulesResponse response = eventBrClient.listRules(rulesRequest);
        List<Rule> rules = response.rules();
        for (Rule rule : rules) {
            System.out.println("The rule name is : " + rule.name());
            System.out.println("The rule description is : " +
rule.description());
            System.out.println("The rule state is : " + rule.stateAsString());
        }

    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [ListRules](#) in *AWS SDK for Java 2.x API Reference*.

ListTargetsByRule

The following code example shows how to use `ListTargetsByRule`.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

List all of the targets for a rule by using the rule name.

```
public static void listTargets(EventBridgeClient eventBrClient, String ruleName)
{
    ListTargetsByRuleRequest ruleRequest = ListTargetsByRuleRequest.builder()
        .rule(ruleName)
        .build();

    ListTargetsByRuleResponse res =
eventBrClient.listTargetsByRule(ruleRequest);
    List<Target> targetsList = res.targets();
    for (Target target: targetsList) {
        System.out.println("Target ARN: "+target.arn());
    }
}
```

- For API details, see [ListTargetsByRule](#) in *AWS SDK for Java 2.x API Reference*.

PutEvents

The following code example shows how to use PutEvents.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
public static void triggerCustomRule(EventBridgeClient eventBrClient, String
email) {
```

```
String json = "{" +
    "\"UserEmail\": \"" + email + "\",\" +
    "\"Message\": \"This event was generated by example code.\",\" +
    "\"UtcTime\": \"Now.\"\" +
    "}";

PutEventsRequestEntry entry = PutEventsRequestEntry.builder()
    .source("ExampleSource")
    .detail(json)
    .detailType("ExampleType")
    .build();

PutEventsRequest eventsRequest = PutEventsRequest.builder()
    .entries(entry)
    .build();

eventBrClient.putEvents(eventsRequest);
}
```

- For API details, see [PutEvents](#) in *AWS SDK for Java 2.x API Reference*.

PutRule

The following code example shows how to use PutRule.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a scheduled rule.

```
public static void createEBRule(EventBridgeClient eventBrClient, String
ruleName, String cronExpression) {
    try {
        PutRuleRequest ruleRequest = PutRuleRequest.builder()
            .name(ruleName)
            .eventBusName("default")
```

```

        .scheduleExpression(cronExpression)
        .state("ENABLED")
        .description("A test rule that runs on a schedule created by the
Java API")
        .build();

    PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
    System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

```

Create a rule that triggers when an object is added to an Amazon Simple Storage Service bucket.

```

// Create a new event rule that triggers when an Amazon S3 object is created in
// a bucket.
public static void addEventRule(EventBridgeClient eventBrClient, String roleArn,
String bucketName,
    String eventRuleName) {
    String pattern = "{\n" +
        "  \"source\": [\"aws.s3\"],\n" +
        "  \"detail-type\": [\"Object Created\"],\n" +
        "  \"detail\": {\n" +
        "    \"bucket\": {\n" +
        "      \"name\": [\"" + bucketName + "\"]\n" +
        "    }\n" +
        "  }\n" +
        "}";

    try {
        PutRuleRequest ruleRequest = PutRuleRequest.builder()
            .description("Created by using the AWS SDK for Java v2")
            .name(eventRuleName)
            .eventPattern(pattern)
            .roleArn(roleArn)
            .build();
    }
}

```

```

        PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
        System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

```

PutTargets

The following code example shows how to use PutTargets.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Add an Amazon SNS topic as a target for a rule.

```

// Add a rule which triggers an SNS target when a file is uploaded to an S3
// bucket.
public static void addSnsEventRule(EventBridgeClient eventBrClient, String
ruleName, String topicArn,
    String topicName, String eventRuleName, String bucketName) {
    String targetID = java.util.UUID.randomUUID().toString();
    Target myTarget = Target.builder()
        .id(targetID)
        .arn(topicArn)
        .build();

    List<Target> targets = new ArrayList<>();
    targets.add(myTarget);
    PutTargetsRequest request = PutTargetsRequest.builder()
        .eventBusName(null)

```

```

        .targets(targets)
        .rule(ruleName)
        .build();

    eventBrClient.putTargets(request);
    System.out.println("Added event rule " + eventRuleName + " with Amazon SNS
target " + topicName + " for bucket "
        + bucketName + ".");
}

```

Add an input transformer to a target for a rule.

```

    public static void updateCustomRuleTargetWithTransform(EventBridgeClient
eventBrClient, String topicArn,
        String ruleName) {
        String targetId = java.util.UUID.randomUUID().toString();
        InputTransformer inputTransformer = InputTransformer.builder()
            .inputTemplate("\nNotification: sample event was received.\n")
            .build();

        Target target = Target.builder()
            .id(targetId)
            .arn(topicArn)
            .inputTransformer(inputTransformer)
            .build();

        try {
            PutTargetsRequest targetsRequest = PutTargetsRequest.builder()
                .rule(ruleName)
                .targets(target)
                .eventBusName(null)
                .build();

            eventBrClient.putTargets(targetsRequest);
        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}

```

- For API details, see [PutTargets](#) in *AWS SDK for Java 2.x API Reference*.

RemoveTargets

The following code example shows how to use RemoveTargets.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Remove all of the targets for a rule by using the rule name.

```
public static void deleteTargetsFromRule(EventBridgeClient eventBrClient, String
eventRuleName) {
    // First, get all targets that will be deleted.
    ListTargetsByRuleRequest request = ListTargetsByRuleRequest.builder()
        .rule(eventRuleName)
        .build();

    ListTargetsByRuleResponse response =
eventBrClient.listTargetsByRule(request);
    List<Target> allTargets = response.targets();

    // Get all targets and delete them.
    for (Target myTarget : allTargets) {
        RemoveTargetsRequest removeTargetsRequest =
RemoveTargetsRequest.builder()
            .rule(eventRuleName)
            .ids(myTarget.id())
            .build();

        eventBrClient.removeTargets(removeTargetsRequest);
        System.out.println("Successfully removed the target");
    }
}
```

- For API details, see [RemoveTargets](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Send event notifications to EventBridge

The following code example shows how to enable a bucket to send S3 event notifications to EventBridge and route notifications to an Amazon SNS topic and Amazon SQS queue.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/** This method configures a bucket to send events to AWS EventBridge and
creates a rule
 * to route the S3 object created events to a topic and a queue.
 *
 * @param bucketName Name of existing bucket
 * @param topicArn ARN of existing topic to receive S3 event notifications
 * @param queueArn ARN of existing queue to receive S3 event notifications
 *
 * An AWS CloudFormation stack sets up the bucket, queue, topic before the
method runs.
 */
public static String setBucketNotificationToEventBridge(String bucketName,
String topicArn, String queueArn) {
    try {
        // Enable bucket to emit S3 Event notifications to EventBridge.
        s3Client.putBucketNotificationConfiguration(b -> b
            .bucket(bucketName)
            .notificationConfiguration(b1 -> b1
                .eventBridgeConfiguration(
                    SdkBuilder::build)
            ).build()).join();

        // Create an EventBridge rule to route Object Created notifications.
        PutRuleRequest putRuleRequest = PutRuleRequest.builder()
            .name(RULE_NAME)
            .eventPattern("""
                {
```

```

        "source": ["aws.s3"],
        "detail-type": ["Object Created"],
        "detail": {
            "bucket": {
                "name": ["%s"]
            }
        }
    }
    """".formatted(bucketName))
    .build();

    // Add the rule to the default event bus.
    PutRuleResponse putRuleResponse =
eventBridgeClient.putRule(putRuleRequest)

Use scheduled events to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

EventBridge Scheduler examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with EventBridge Scheduler.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge Scheduler

The following code examples show how to get started using EventBridge Scheduler.

SDK for Java 2.x

Note

Scenarios

Scheduled Events

The following code example shows how to:

- Deploy a AWS CloudFormation stack with required resources.
- Create a EventBridge Scheduler schedule group.
- Create a one-time EventBridge Scheduler schedule with a flexible time window.
- Create a recurring EventBridge Scheduler schedule with a specified rate.
- Delete EventBridge Scheduler the schedule and schedule group.
- Clean up resources and delete the stack.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run the scenario.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.scheduler.model.SchedulerException;
import javax.mail.internet.AddressException;
import javax.mail.internet.InternetAddress;
import java.time.LocalDateTime;
import java.time.format.DateTimeFormatter;
import java.util.Map;
import java.util.Scanner;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.CompletionException;

/**
 * This Java code example performs the following tasks for the Amazon EventBridge
 * Scheduler workflow:
 * <p>
 * 1. Prepare the Application:
```

```

* - Prompt the user for an email address to use for the subscription for the SNS
topic subscription.
* - Deploy the Cloud Formation template in resources/cfn_template.yaml for resource
creation.
* - Store the outputs of the stack into variables for use in the workflow.
* - Create a schedule group for all workflow schedules.
* <p>
* 2. Create one-time Schedule:
* - Create a one-time schedule to send an initial event.
* - Use a Flexible Time Window and set the schedule to delete after completion.
* - Wait for the user to receive the event email from SNS.
* <p>
* 3. Create a time-based schedule:
* - Prompt the user for how many X times per Y hours a recurring event should be
scheduled.
* - Create the scheduled event for X times per hour for Y hours.
* - Wait for the user to receive the event email from SNS.
* - Delete the schedule when the user is finished.
* <p>
* 4. Clean up:
* - Prompt the user for y/n answer if they want to destroy the stack and clean up
all resources.
* - Delete the schedule group.
* - Destroy the Cloud Formation stack and wait until the stack has been removed.
*/

        Amazon EventBridge Scheduler is a fully managed service that helps you
schedule and execute
        a wide range of tasks and events in the cloud. It's designed to simplify
the process of
        scheduling and managing recurring or one-time events, making it easier
for developers and
        businesses to automate various workflows and processes.

        One of the key features of Amazon EventBridge Scheduler is its ability
to schedule events
        based on a variety of triggers, including time-based schedules, custom
event patterns, or
        even integration with other AWS services. For example, you can use
EventBridge Scheduler
        to schedule a report generation task to run every weekday at 9 AM, or to
trigger a
        Lambda function when a specific Amazon S3 object is created.

        This flexibility allows you to build complex and dynamic event-driven
architectures
        that adapt to your business needs.

        Lets get started...

Forecast examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Forecast.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

AWS Glue examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS Glue.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS Glue

The following code examples show how to get started using AWS Glue.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
package com.example.glue;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.ListJobsRequest;
import software.amazon.awssdk.services.glue.model.ListJobsResponse;
import java.util.List;

public class HelloGlue {
    public static void main(String[] args) {
        GlueClient glueClient = GlueClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listJobs(glueClient);
    }

    public static void listJobs(GlueClient glueClient) {
        ListJobsRequest request = ListJobsRequest.builder()
            .maxResults(10)
            .build();
        ListJobsResponse response = glueClient.listJobs(request);
        List<String> jobList = response.jobNames();
        jobList.forEach(job -> {
            System.out.println("Job Name: " + job);
        });
    }
}
```

- For API details, see [ListJobs](#) in *AWS SDK for Java 2.x API Reference*.

Topics

- [Basics](#)
- [Actions](#)

Basics

Learn the basics

The following code example shows how to:

- Create a crawler that crawls a public Amazon S3 bucket and generates a database of CSV-formatted metadata.
- List information about databases and tables in your AWS Glue Data Catalog.
- Create a job to extract CSV data from the S3 bucket, transform the data, and load JSON-formatted output into another S3 bucket.
- List information about job runs, view transformed data, and clean up resources.

For more information, see [Tutorial: Getting started with AWS Glue Studio](#).

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To set up the resources, see this documentation topic:
 *
 * https://docs.aws.amazon.com/glue/latest/ug/tutorial-add-crawler.html
 *
```

```

* This example performs the following tasks:
*
* 1. Create a database.
* 2. Create a crawler.
* 3. Get a crawler.
* 4. Start a crawler.
* 5. Get a database.
* 6. Get tables.
* 7. Create a job.
* 8. Start a job run.
* 9. List all jobs.
* 10. Get job runs.
* 11. Delete a job.
* 12. Delete a database.
* 13. Delete a crawler.
*/

public class GlueScenario {

    System.out.println("Welcome to the AWS Glue scenario.");
    System.out.println("""
        AWS Glue is a fully managed extract, transform, and load (ETL) service
provided by Amazon
        Web Services (AWS). It is designed to simplify the process of building,
running, and maintaining
        ETL pipelines, which are essential for data integration and data
warehousing tasks.

        One of the key features of AWS Glue is its ability to automatically
discover and catalog data
        stored in various sources, such as Amazon S3, Amazon RDS, Amazon
Redshift, and other databases.
        This cataloging process creates a central metadata repository, known as
the AWS Glue Data Catalog,
        which provides a unified view of an organization's data assets. This
metadata can then be used to
        create ETL jobs, which can be scheduled and run on-demand or on a
regular basis.

        Lets get started.

HealthImaging examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with HealthImaging.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.
